Messrs Chas Griffin and Co, Limited, will issue "Diseases of the Heart (Diagnosis of)," by A Ernest Sansom, M D, F R C P, with 13 plates and illustrations in the text, "Ruptures, a Treatise on," by J F C Macready, F R C S, with numerous plates engraved on the stone after photographs, "Clinical Diagnosis the Chemical, Microscopical, and Bacteriological Evidence of Disease," by Prof von Jaksch, of Prague, translated from the third German edition by Jas Cagney, M D, with additional illustrations, many in colours, second edition, "The Diseases of Children Medical and Surgical," by H Bryan Donkin, M B, F R C P, and Bilton Pollard, M D, F R C S, "Gynæcology," a practical treatise on, by J Halliday Croom, M D, with the collaboration of MM. Milne Murray, M B, and Johnson Symington, M D, "Midwifery," a practical treatise on, by John Phillips, M D, "A Manual of Obstetrics," for the use of students, nurses, and midwives, by Arch. Donald, M D, "Forensic Medicine and Toxicology" (a text book of), by J Dixon Mann, M D, F R C.P, "A Medical Handbook for the Use of Students," by R S Aitchison, M B, F R C P, Edin, "Inorganic Chemistry" (a Text-Book of), by Dr Dupré, F R S, and Dr Wilson Hake, second edition, revised, "Mind in Matter," by the Rev James Tait, third edition, revised and enlarged, with special reference to later Darwinism, "Biology" (a Text-Book of), by Prof. J R Ainsworth Davis, new edition, revised and enlarged, in two parts (1) Vegetable Morphology and Physiology, (2) Animal Morphology and Physiology, with additional illustrations, "Coal Mining" (a Text-Book of), by H W Hughes, F.G S, with frontispiece and 490 illustrations, reduced from working drawings; "Ore and Stone Mining," by Prof. C Le Neve Foster, D Sc, with numerous illustrations; "Dyeing" (a manual of), for the use of practical dyers, manufacturers, and students, by Dr Knecht, Chr Rawson, and Dr. R Loewenthal, with numerous illustrations and specimens of dyed fabrics,

"Oils, Fats, Waxes, and Allied Materials, and the Manufacture therefrom of Candles, Soaps, and other Products," by C R Alder Wright, D Sc, F R S, with numerous illustrations, "Painters' Colours, Oils, and Varnishes" (a practical Manual), by Geo H Hurst, with illustrations, "Applied Mechanics (an Elementary Manual of), for first year students, by Prof A Jamieson, F R S E, with very numerous illustrations, and "Griffin's Electrical Price Book," for the use of electrical, civil, marine, and borough engineers, local authorities, architects, railway contractors, &c, edited by H J Dowsing

MESSRS SWAN SONNENSCHEIN AND CO's list contains — "Text Book of Embryology Man and Mammals," by Dr Oscar Hertwig, translated and edited from the third German edition by Dr E L Mark, fully illustrated, "Text-Book of Embryology Invertebrates," by Drs Korschelt and Heider, translated and edited by Dr E L Mark and Dr W M Woodworth, fully illustrated, "Text Book of Comparative Geology," adapted from the work of Dr Kayser, by Philip Lake, fully illustrated, "Text Book of Palæontology for Zoological Students," by Theodore T Groom, fully illustrated, "Text Book of Petrology," by F H Hatch, D Sc, a revised and enlarged edition of "An Introduction to the Study of Petrology, with 86 illustrations, "Handbook of Systematic Botany," by Dr F Warming, translated and edited by M C Potter, fully illustrated "Practical Bacteriology," by Dr Migula, translated and edited by H J Campbell, M D, "The Geographical Distribution of Disease in England and Wales," by Alfred Haviland, M D, with several coloured maps, "A Treatise on Public Hygiene and its applications in different European Countries," by Dr Albert Palmberg, translated, and the English portion edited and revised, by Arthur Newsholme, M D, fully illustrated, "The Photographer's Pocket Book," by Dr E Vogel, translated by F C Conrad, illustrated, "The Recrudescence of Leprosy and the Report of the Leprosy Commission," by William Tebb, "Roaring in Horses its Pathology and Treatment," by P J Cadiot, translated by Thomas J Watt Dollar, M R C V S "Introductory Science Text-Books" additions—Introductions to the Study of "Zoology," by B Lindsay, illustrated, 'The Amphioxus," by Dr B Hatschek and James Tuckey, illustrated, "Geology," by Edward B Aveling, D Sc (Lond), illustrated, "Physiological Psychology," by Dr Th Ziehen, adapted by Dr Otto Beyer and C C Vanliew, with 21 illustrations, "Biology," by H J Campbell, M D "Young Collector Series" additions—"Flowering Plants," by James Britten, F L S, "Grasses," by W Hutchinson, "Fishes" by the Rev H C Macpherson, and "Mammalia," by the Rev H C Macpherson

THE SOCIETY FOR PROMOTING CHRISTIAN KNOWLEDGE has nearly ready for publication —"Star Atlas," gives all the stars from 1 to 6 5 magnitude between the North Pole and 34° south declination and all nebulæ and star clusters which are visible in telescopes of moderate powers, translated and adapted from the German of Dr Klein, by the Rev E McClure, M A, new edition brought up to date, with eighteen charts and eighty pages illustrative letterpress "Vegetable Wasps and Plant Worms," by M C Cooke, LL D, illustrated "Our Secret Friends and Foes," by Prof Frankland, F R S

MESSRS LONGMANS AND CO are preparing for publication —"The Ruined Cities of Mashonaland being a Record of Excavations and Explorations, 1891–92," by J Theodore Bent, F R G S., with numerous illustrations of Mashonaland, and of the author's interesting discoveries of the remains of a prehistoric people at the Zimbabwe ruins. An English translation of Wüllner's "Lehrbuch der Electricitat," in 2 vols, translated and edited by G W de Tunzelmann, B Sc, with 310 illustrations. The English editor has added much new matter, and by some changes of arrangement and mode of presenting the subject has endeavoured to make it a truthful representation of the present state of electrical science "Chemical Lecture Experiments," by G S. Newth

MESSRS LAWRENCE AND BULLEN will publish —"Matriculation Chemistry," by Temple Orme

MESSRS. J AND A CHURCHILL promise "Physiology" (Student's Guide Series), by E H Starling, M D. Lond, with 100 illustrations, "A Guide to the Science of Photo-micrography," by Edward C Bousfield, second edition, with 34 woodcuts and frontispiece, "Chemical Technology or, Chemistry in its application to Arts and Manufactures," with which is incorporated "Richardson and Watts' Chemical Technology," edited by Charles Edward Groves, F.R S., and William Thorp, B Sc vol. ii Lighting—Sections Stearine, by Mr John McArthur, Candles, by Mr Field, Oils, Oil Fields, Lamps, by Boverton Redwood, Gas, by Chas Hunt, Electric Lighting, by Prof Garnett, "Commercial Organic Analysis," by Alfred H Allen, F I C, F C S A treatise on the properties, proximate analytical examination, and modes of assaying the various organic chemicals and products employed in the arts, manufactures, medicine, &c, with concise methods for the detection and determination of their impurities, adulterations, and products of decomposition Vol iii, Part 2, Organic bases, cyanogen compounds, albuminoids, &c "Wilson's Anatomy," edited by Prof Henry E Clark, eleventh edition, with 26 coloured plates, and 492 woodcuts, "Morris's Anatomy," a treatise by various authors J B Sutton, H Morris, J N Davies Colley, W J Walsham, H St John Brooks, R M Gunn, A Hensman, F Treves, W Anderson, and W H A Jacobson, with more than 500 illustrations, many being coloured, "Ambulance Lectures," to which is added a Nursing Lecture, in accordance with the regulations of the St John Ambulance Association, by John M H Martin, M D, third edition, with 60 engravings, 142 pp, and an English edition of Tommasi Crudeli's well known work on the Climate of Rome

MR LEWIS'S announcements are —"Various Forms of Hysterical or Functional Paralysis," by H C Charlton Bastian, M D, F R S, "Diseases of the Skin Their Description, Pathology, Diagnosis and Treatment," by H Radcliffe Crocker, M D, F R C P, second edition, with numerous illustrations, "A Text book of Ophthalmology," by Dr Ernest Fuchs, translated from the German by A Duane, M D, in one large octavo volume, with 178 illustrations, "Public Health Laboratory Work," by H R Kenwood, M B, with illustrations, "Hygiene and Public Health," by Lucius C Parkes, M D, third edition, with numerous illustrations, "A Handbook of the Diseases of the Eye and their Treatment," by Henry R Swanzy, M B, F R C S I, fourth edition, illustrated with wood engravings, colour tests, etc "A Pharmacopœia for Diseases of the Skin," edited by James Startin, third edition, and "The Sanitary Inspector's Handbook and Text book for Students preparing for the Examinations of the Sanitary Institute, London," by Albert Taylor, with illustrations

MESSRS G PHILIP AND SON have in the press —"British New Guinea," a compendium of all the most recent information respecting our Papuan Possession, by J P Thomson, with valuable scientific appendix dealing with the Geology, Fauna, Flora, &c, illustrated with numerous engravings and photographs, and a coloured map, "Christopher Columbus," by Clements R Markham, C B, forming vol vii of the World's Great Explorers and Explorations, with 25 illustrations and numerous coloured maps, "The Development of Africa," a Study in Applied Geography, by Arthur Silva White, illustrated with a set of 14 coloured maps, specially designed by E G Ravenstein, F R G S, second edition, revised to April 1892, "Atlas of Astronomy," a Series of Seventy-two beautifully executed Plates, with Explanatory Notes, by Sir Robert Stawell Ball, F R S, "Astronomy for Every Day Readers," and a Popular Manual of Elementary Astronomy, by B J Hopkins, with numerous illustrations

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, Sept 12 —M. Duchartre in the chair —On the heat of combustion of glycolic acid, by M Berthelot —Note on several new facts relating to the physiology of epilepsy, by M Brown-Sequard If by epilepsy is understood a group of reflex convulsive movements, it is invariably induced in guinea-pigs by cutting one of the sciatic nerves. If, however, the section has been made in the lower part of the thigh, the convulsive manifestations often are confined to the side of the lesion, and the animal retains consciousness. This is due to the regeneration of the nerve, which takes place rapidly, and which stops the development of the disease, or even cures it altogether. Generally, the greater the number of nerve fibres severed, the stronger is the tendency towards epileptic fits. A set of absolutely decisive facts have shown that a violent attack can be produced which is due to the spinal marrow alone. This epilepsy as displayed in guinea pigs is absolutely equivalent to the idiopathic or cerebral disease in man. Clinical as

well as experimental facts show that epilepsy has no special seat in the brain, but that all parts of the nervous system, central or peripheral, may give rise to it.—The meadows in the dry summer of 1892, by M. A. Chatin.—Absolute positions and proper motions of circumpolar stars, by M. F. Gonnessiat.—On a problem of analysis involved in the equations of dynamics, by M. R. Liouville.—On a recurring series of pentagons inscribed in the same general curve of the third order, which can be constructed with the sole help of the straight edge, by M. Paul Serret.—On the calorific distribution of the heat of the sun at the surface of the northern and southern hemispheres of the terrestrial globe, by M. le Goarant de Tromelin. It is sometimes thought that the fact of the sun being eight days longer in the northern hemisphere than in the southern, is the principal cause of the inequality of the distribution of heat in the two hemispheres. It can, however, be shown that the quantities of heat received by two symmetrical elements of the earth's surface, or by two caps symmetrical with respect to the earth's centre, are the same during the durations of the earth's journey comprised between two pairs of opposite vectors. Hence the total heat received by the northern hemisphere during spring and summer is equal to that received by the southern hemisphere during autumn and winter. The true cause of the difference of mean annual temperature in the two hemispheres lies in the difference of loss by radiation. By the law of cooling bodies, if two bodies have the same mean temperature, but different extremes, the one with the greatest extremes will lose most heat by radiation. Thus the southern hemisphere, which is nearer the sun in its summer and further away in its winter than the northern, will lose the greater quantity of heat.—Theory of a condenser interposed in the secondary circuit of a transformer, by M. Désiré Korda.—On the thermal variation of the electrical resistance of mercury, by M. Ch. Ed. Guillaume. The relation between temperature and conductivity was determined by comparing the resistance of a mercury standard of about one ohm at different temperatures with another standard maintained at a constant temperature, with a special arrangement to eliminate the resistances of the contacts. The formula deduced was—

$$\rho_T = \rho_0(1 + 0.00088879T + 0.00000102221T^2),$$

and the value of the standard mercury ohm—

$$106.3 \frac{\text{cm}}{(\text{microlitre})^{\frac{1}{2}}} \text{ Hg at } 0^{\circ}$$

—On a ptomaine obtained from a cultivation of *Micrococcus tetragenus*, by M. A. B. Griffiths. This Micrococcus, found associated with human phthisis, gives rise to a ptomaine if cultivated on peptonised gelatine for several days. This ptomaine is a white solid, crystallizing in prismatic needles. It is soluble in water, giving a feeble alkaline reaction. It forms a chlorohydrate, a chloroaurate, and a chloroplatinate, all crystallizable. Nessler's reagent gives a green precipitate, tannic acid a brown one, slightly soluble. The formula appears to be $C_5H_8NO_2$. It is a poison, and produces death in thirty-six hours. It is undoubtedly the product of the decomposition of the albumin by the microbe.—On echinochrome, a respiratory pigment, by M. A. B. Griffiths. Mr. McMunn discovered a brown pigment in the perivisceral fluid of certain echinoderms in 1883. This was separated by desiccating the fluid and dissolving out by chloroform. The formula of echinochrome is $C_{102}H_{99}N_{12}FeS_2O_{12}$. It serves a purpose in the body of the echinoderm analogous to that of hæmoglobine in the human body, but is not so highly developed as the latter. The respiratory pigments in the lower animals not only carry oxygen to the tissues, but also retain oxygen in combination till taken up by the cellules. Hence echinochrome, like hæmocyanine, chlorocruorine, and similar bodies, is more stable than hæmoglobine.—Physiology of the pancreas, experimental dissociation of the external and internal secretions of the glands, by M. J. Thiroloix.—Influence of some deleterious gases on the progress of anthrax infection, by MM. A. Charrin and H. Roger.—Contribution towards the aseptic method in hypodermic therapeutics, by M. Barthélémy.—On the construction of a luminous fountain with automatically variable colours, by M. G. Trouvé.

BOOKS, PAMPHLETS, and SERIALS RECEIVED

BOOKS.—The Locomotive Engine and its Development: C. E. Stretton (Lockwood).—Universal Atlas, Part 18 (Cassell).—Life Histories of North American Birds: C. Bendire (Washington).—Traité Encyclopédique de Photographie: C. Fabre. Premier Supplément (Paris, Gauthier-Villars).—VI. Jahresbericht (1890) der Ornithologischen Beobachtungsstationen im Königreiche Sachsen: A. B. Meyer u. F. Helm (Berlin, Friedländer).—Elementary Physiography: R. A. THE SPEECH OF MONKEYS

The Speech of Monkeys By R L Garner (London Heinemann, 1892)

IT is somewhat unfortunate, and is certainly not a little embarrassing to the critic who desires to take Mr Garner seriously, that he has chosen to present to the world "this first contribution to science on the subject" of the speech of monkeys in the form of popular and chatty anecdotes, with reflections thereon suitable for the delectation of elderly spinsters This is the style of writing to which we refer, and of which the book before us largely consists

"I shall long remember how this dear little monk (Pedro the Capuchin) would cuddle up under my chin, and try so hard to make me understand some sad story which seemed to be the burden of his life I have frequently been entertained by a like speech from little Dodo, who was the Juliet of the Simian tribe She belonged to the same species as the others, but her oratory was of a type far superior to that of any other of its kind that I have ever heard At almost any hour of the day, at the approach of her keeper she would stand upright and deliver to him the most touching and impassioned address The sounds which she used, and the gestures with which she accented them, as far as I could determine, were the same as those used by Dago and Pedro in their remarks to me as above described, except that Dodo delivered her lines in a much more impressive manner than either of the others I have not been able up to this time to translate these sounds literally, but their import cannot be misunderstood My belief is that her speech was a complaint against the inmates of the cage, and that she was begging her keeper not to leave her alone in that great iron prison with all those big, bad monkeys who were so cruel to her"

This is the anecdotal style, the heading of the chapter in which Dodo is introduced running thus "Dago talks about the Weather—Tells Me of His Troubles—Dodo in the 'Balcony Scene,'" &c It is not easy, we repeat, to deal with this kind of thing in a spirit of serious criticism And then we have passages of which the following is a sample —

"I assert that all mammals reason by the same means and to the same ends, but not to the same degree The reason which controls the conduct of a man is just the same in kind as that which prompts the ape That same faculty which guided man to tame the winds of commerce, taught the nautilus to lift its tentacles and embrace the passing breeze That psychic spark which dimly glows in the animal bursts into a blaze of effulgence in man The one differs from the other just as a single ray of sunlight differs from the glaring light of noon. If man could disabuse his mind of that contempt for things below his plane of life, and hush the siren voice of self conceit, his better senses might be touched by the eloquence of truth But while the vassals of his empty pride control his mind, the plainest facts appeal to him in vain, and all the cogency of proof is lost. He is unwilling to forego that vain belief that he is Nature's idol, and that he is a duplicate of Deity Held in check by the strong reins of theology and tradition"—and so forth for another page, and a half

These be the reflections suitable for the delectation of elderly spinsters. We must excuse ourselves from criticising Mr Garner's remarks on reason in animals, for there is no evidence in his book that he has, by a careful training in psychology, earned for himself the right of expressing a scientific opinion on this difficult question

And yet Mr Garner is at work upon an interesting and important problem in the elucidation of which scientific results will be of great value, and he is working on the right lines, namely, those of experiment and observation in close contact with phenomena It is worth while therefore, to dig out from his volume the few results of scientific value he has at present reached, to endeavour to set them in their true light, and to encourage him in the further prosecution of his labours

It is well known to all observers that animals emit sounds expressive of their emotional states, and that these sounds convey, and are often apparently intended to convey, an intimation to their fellow creatures of such emotional states No one who has watched a dog growling, a cat swearing, or a lamb bleating, can question this elementary fact The present writer has lately been observing and making experiments with young chicks Towards the close of the first week there were at least five well-distinguished sounds the soft "cheep" of contentment, the more excited note of unusual satisfaction, the complaining "weep-weep" of slight discomfort, the sharper cry when they were caught up, for example, by a strange hand, and, quite distinct from all the rest, the danger 'churr" There can be little doubt that these several sounds, as emitted by one of the chicks, were of suggestive value to its little brothers and sisters And they were quite spontaneous and not the result of imitation, for the chicks had never seen any of their kind Had these chicks been reared in the ordinary way, and not as experimental orphans, their hen mother would no doubt have given opportunity for observing that by certain sounds she could call her brood's attention to things good to eat And there can be little doubt that a dog can call its companion's attention to something worriable, though whether there are differentiations, *e g*, for cat and rat, we cannot say We have ourselves been unable to detect such differences in our own dogs

It is thus a matter of familiar observation that animals emit sounds which are of suggestive value, and that these sounds are in some cases suggestive of emotional states, and in others of external objects It is to such sounds as emitted by monkeys that Mr Garner has mainly directed his attention Let us give in his own words some of his results —

"Standing near the cage of a little Capuchin, I imitated a sound which I had translated 'milk,' but from many tests I concluded it meant 'food,' which opinion has been somewhat modified by many later experiments which led me to believe that he uses it in a still wider sense It is difficult to find any formula of human speech equivalent to it While the Capuchin uses it relating to food and sometimes to drink, I was unable to detect any difference in the sounds. He also seemed to connect the same sound to every kindly office done him, and to use it as a kind of 'shibboleth' More recently, however, I have detected in the sound slight changes of inflection under different conditions, until I am now led to believe that the meaning of the word depends somewhat, if not wholly, on its modulation"

Again —

"I approached the cage [of another Capuchin], and uttered the sound which I have described and translated

'drink' My first effort caught his attention and caused him to turn and look at me; he then arose and answered me with the same word, and came at once to the front of the cage. He looked at me as if in doubt, and I repeated the word; he responded with the same, and turned to a small pan in his cage which he took up and placed near the door, through which the keeper usually passed his food, returned to me, and uttered the word again. I asked the keeper for some milk, which he did not have, but brought me some water instead. I allowed the monkey to dip his hand into the glass, and he would then lick the water from his fingers and reach again. I kept the glass out of reach of his hand, and he would repeat the sound earnestly, and look at me beseechingly, as if to say, 'Please give me some more.' I was thus convinced that the word which I had translated 'milk,' must also mean 'water,' and from this and other tests I at last determined that it meant 'drink' in its broad sense, and possibly 'thirst.' It evidently expressed his desire for something with which to allay his thirst. The sound is very difficult to imitate, and quite impossible to write exactly."

We submit that these passages seem to indicate that Mr. Garner has not yet, in this matter, reached results which have much definiteness and precision. It would seem that the Capuchin emits sounds which are mainly expressive of a craving for something, and perhaps vaguely indicate that this something is water or other drink; though with regard to this objective implication we must remember that one of the capuchins "seemed to connect this sound to every kindly office done him."

This is one of the nine words or sounds belonging to Capuchins. Another is the sound which Mr. Garner has translated "food." Of it he says:—

"I observed that this sound seemed to be a salutation or peace making term with them, which I attributed to the fact that food was the central thought of every monkey's life, and that consequently that word would naturally be the most important of his whole speech."

Another sound which was emitted by a monkey when a storm was going on, and which, when reproduced by the phonograph, made the little fellow look out of window, Mr. Garner translated "weather," or thought that it "in some way alluded to the state of the weather." But he does not seem quite clear about it.

"I am not sure," he says, "how far it may be relied upon as a separate word. It was so closely connected to the speech of discontent or pain, that I have not been able since to separate the sounds, and I finally abandoned it as a separate word; but reviewing my work, and recalling the peculiar conduct of this monkey and the conditions attending it, I believe it is safe to say that he had in mind the state of the weather."

Three other sounds are plainly emotional in their nature—(1) an alarm sound, used under stress of great fear, high in pitch, shrill and piercing; (2) a sound written thus "e-c-g-k" expressive of apprehension; and (3) a sound which is like a guttural whisper "c-h-t" expressive of the approach of something which the monkey does not fear.

Such are some of the sounds which Mr. Garner misnames (as we think) the "speech" of monkeys, and concerning which he exclaims:—

"Standing on this frail bridge of speech, I see into that broad field of life and thought which lies beyond the confines of our care, and into which, through the gates that I have now unlocked, may soon be borne the sunshine of human intellect. What prophet now can foretell the relations which may yet obtain between the human race and those inferior forms which fill some place in the design, and execute some function in the economy of nature?"

This, however, is one of those reflections which savour of the prattle of the parlour tea-table rather than the sober discussion of the study. We should rather say that Mr. Garner's investigations, if followed up in a spirit of critical accuracy, give promise of enabling him to extend our knowledge of the sounds emitted by monkeys—sounds which, we gather from his descriptions, are mainly, if not entirely, of emotional origin, but which may perhaps carry with them a more or less definite objective import. We are of opinion that such extension of our knowledge of these emotional or other sounds may prove a definite and valuable contribution to science, and we therefore heartily wish Mr. Garner all success in the prosecution of his inquiry.

C. Ll. M.

BEE-KEEPING.

Bees for Pleasure and Profit. By G. Gordon Samson. (London: Crosby Lockwood and Son, 1892.)

"HOW doth the little busy bee, &c.?" asked Dr. Watts a hundred and fifty years ago. So long as straw skeps predominated, the problem was insoluble. The bees improved each shining hour in perfunctory fashion, building crooked combs, confusing brood with honey, exhausting their republic with superfluous swarms, dying finally in the smoke-reek of an old pair of corduroys, enriched for malarious exhalation by more than one generation of bucolic wearers. With frame hives came an Earthly Providence to answer the pious query; to control the economy of the hive, to prescribe the number of drones, multiply or restrict the queens, straighten out the combs, combine defective stocks into a single opulent society, disintegrate an overgrown community into new and independent nuclei, supplement the tardy growth of brood or honey, increase fourfold the productiveness of every hive. It is as an adept in Providential operations that Mr. Samson writes. He renounces scientific erudition; and his allusion to "powerful microscopes," his reliance on "wonderful provisions of Nature," his belief that by confining their visits to one kind of flower in a single journey the bees prevent the hybridization of species, show his disclaimer to be correct; but apiarian science was brought up to date last year in Mr. Cowan's admirable book (NATURE, vol. 43, p. 578), leaving room for just such a practical treatise on manipulation and management as Mr. Samson is competent to give.

No repetition can exhaust the interest attaching to the strange life-history of the hive bees. While the solitary bees are created male and female, there appears in the gregarious bees a third sex, the workers or neuters (not *neutrals*, as Mr. Samson calls them), having rudimentary ovaries and spermatotheca, incapable of laying eggs, with the ovipositor modified into a sting; themselves, in queenless hives, sometimes developed into more advanced yet still imperfect females, known as fertile workers, and producing only drones. In ordinary cases a single queen is the mother of the entire hive, bearing drone eggs only in her virgin state, fecundated once for all by a solitary nuptial act for the production of more

than half a million of offspring During twenty-one days as egg, larva, pupa, the infant bee resides in the comb, fed by its older sisters on a paste of brood-food or chyle, to which in the case of workers honey is added after the first three days For a week after emergence the young bee remains at home in order to secrete wax, which is detached from the wax pockets by others, it is then promoted to the office of nurse, for a fortnight or three weeks afterwards it gathers honey, spends its maturity in the difficult work of comb-building, dies at the end of six or seven weeks, unless winter hibernation arrests its labour and prolongs its life The moral of its unique biography has been pointed by many writers, the social lesson of its communistic orderliness, the industrial ideal flowing from its co-operative toil and profit, the political example impressed by the curious completeness with which, at once a red republican and an ardent cavalier, it combines extremest democratic sturdiness with devoted personal loyalty

The common hive bee, as distinguished from the Bumble, Carpenter, Mason, and other bees, belongs to the genus Apis, of which one species only, *A mellifica*, is indigenous to Britain During the last few years the Ligurian, Carniolian, and Syrian bees have been largely introduced, from amongst which the cross known as Syrio-Carniolian bears the palm for fecundity, docility, honey-gathering, and hardiness through the winter With a swarm of these and a ten-frame hive the tyro may begin bee-keeping In manipulating he must not wear gloves, they make the fingers clumsy, and the sting, painful at first, causes diminishing inconvenience on each successive infliction, till the system is inoculated by the acid, and the sting is harmless In creating their new home the bees require assistance, one or two frames of brood-comb from the parent hive, with a limited number of drone cells, must be inserted As the frames fill, the master, utilizing the fact that honey is always stored above the brood, places "supers" over the frames, removing them as fast as they are filled, while the full-charged combs from below are placed in an extractor and the liquid honey is withdrawn As much as 100 pounds of honey have sometimes been thus obtained in one season from a single hive The honey harvest begins with the blooming fruit trees in early spring, and slackens after the lime trees fade, but in heather districts a rich autumn store is raised, and Scottish bee-keepers, having reaped the early crop from bean and clover, send their hives by rail or boat to a considerable distance, to be placed upon the heath-clad moors in early August When an unfavourable winter has depopulated the hives, it is possible to build up one strong colony out of two or more weak stocks, retaining only the youngest and most prolific queen The bees will resent the coalition, and a general fight will impend, but if sprinkled with thin syrup and with flour their power of discerning Trojan from Tyrian is cancelled by the identity of appearance and o scent.

> "Just so the prudent husbandman, that sees
> The idle tumult of his factious bees,
> Powders them o'er, till none discern his foes,
> And all themselves in meal and friendship lose.
> The insect kingdom straight begins to thrive,
> And all work honey for the common hive."

Mr. Samson does well to press the economic value of bees not only as honey-makers, but as fruit-setters. In cold sunless springs their agency is essential to the fertilization of the bloom, in districts adjoining a large apiary the fruit trees are invariably laden with heavy crops, deteriorating as we remove further from its neighbourhood, and instances are well authenticated from the cider counties in which a general destruction of bees by a long and variable winter has been followed by the loss of the apple crop Both fruit and honey are at present for the most part imported from abroad, if fruit is to be largely cultivated in the small holdings of the future, it must be sustained and enriched by bee-keeping

In this, as in other industries, there are occasional difficulties baffling to all but experts Queens will refuse to be reared, supers will remain unfilled, stocks will need stimulation in the spring and building up in early winter, foul brood, deadliest of bee maladies, will infect the hive In all such complications and for many more Mr Samson offers full and clear instruction Portable in form and cheap of cost, his book should form part, along with "smoker," bee veil, queen cage, "driving irons," and "doubling box," of every bee-keeper's equipment

W TUCKWELL.

A NEW COURSE OF CHEMICAL INSTRUCTION

A New Course of Experimental Chemistry, with Key By John Castell-Evans, F I C (London Thomas Murby)

THE basis of the course of instruction here put forward consists in making the student perform an experiment with a definite object in view The result of the experiment is carefully withheld, and must be discovered by the student himself In this way he is led to acquire knowledge by his own exertions, and theoretically at least such a method has more to recommend it than any other In practice, however, the time required to rigorously carry out this system is no doubt an obstacle to its general adoption.

If with the author we lay down the law that "the student must not be allowed to use any chemical *name* or *term* until he has discovered for himself the *thing* or *process* represented by it," to acquire but a moderate knowledge of the chemistry of to-day appears well-nigh an impossibility It was thus a matter of interest to see how a work based on this system could be comprised within reasonable limits of space The author, however, does not seem to intend the above restriction to be literally enforced To go no further than the first lesson, we find the student employing the ordinary chemicals, phosphorus, ammonium nitrite, potassium chlorate, &c, things which he makes no attempt to discover, only in the case of the more important processes and substances usually met with in a chemical course is any such attempt made.

The book consists of two parts The first part contains a series of experiments and problems, the latter being set upon a course of lectures which are intended to be given concurrently with the laboratory instruction, and which deal more especially with the physical aspect of the subject Outlines of these lectures, results of the experiments, and full solutions of the problems are to be found in the Key, which may be obtained separately or bound up with the

two parts The experiments start off with the commonly occurring phenomena of combustion, and lead up to the laws of chemical combination, the determination of chemical equivalents, vapour densities, &c

Part II consists of qualitative and quantitative analysis taken together, no attempt being made to separate the two The results of the experiments are here carefully withheld from the student, and are given in the Key A useful table for the detection of the positive radicles is published separately, and may be used in connection with this part

The book can be recommended as a trustworthy one, and, apart from the novelty of the system adopted, as a storehouse of knowledge useful to the chemist, it will be appreciated by many a teacher

The problems are actual examples met with in the laboratory, and appear to be free from the artificial exercises so common in text books It is also noteworthy that they, as well as the lectures, are concerned to a considerable extent with the energy changes as well as with the material changes which constitute chemical phenomena

In glancing at the tables of physical constants to be found as answers in the Key, it is frequently noticeable that these magnitudes are given to an accuracy which is altogether fictitious For example, to express heats of vaporization or absorption coefficients to one part in thousands of millions, or to give a boiling point such as that of bromine to one thousandth of a degree Fahrenheit, tends to create an erroneous idea of the accuracy with which such determinations can be made In one or two instances the information is not quite up to date Hydrofluoric acid, for instance, is still formulated H_2F_2, and Bunsen's values for the absorption coefficients of hydrogen and oxygen are still given, although they have been superseded by the observations of Winkler and Timoféef Van der Waals's work might have been included in the otherwise serviceable account of the kinetic theory of gases, and it is somewhat unfortunate that the author insists upon the narrow view that specific gravity has no other meaning than that which is perhaps more correctly attributed to relative density

The printing and the woodcuts are hardly up to the standard usually attained in books of this kind

J W R

OUR BOOK SHELF

Die Pflanze in ihren Beziehungen zum Eisen Von Dr Hans Molisch Iron in its Relations to Plant-life 8vo, 119 pages, with one coloured plate (Jena Gustav Fischer, 1892)

AN interesting essay on the presence, function, and form of iron in plants, embodying the results of previous investigators and of the author's experiments and researches extending over several years Though the outcome of much labour, Dr Molisch regards it as preliminary to more extended inquiries, and the whole subject as being yet in its infancy He discusses the determination of the presence in the vegetable cell of iron in loose combinations and in dense combinations, or what he terms the masked condition He then describes the occurrence and distribution of iron in plants in loose and dense combinations, and enters somewhat fully into the description of a new method he claims to have discovered for proving the existence of iron in the masked condition, even when it is present only in infinitesimally small quantities This is done by soaking the objects one or more days or weeks in saturated aqueous liquor potassæ, and then, after quickly washing them in pure water, subjecting them to the usual reagents He further claims to have proved that iron is not one of the constituents of chlorophyll There is also a short chapter on healing vegetable chlorosis by the use of chloride of iron, sulphate of iron, and other salts of iron W B H

Up the Niger By Captain A F Mockler-Ferryman (London George Philip and Son, 1892)

SEVERAL years ago complaints were made about the conduct of various British subjects in the territories placed under the Royal Niger Company The British Government accordingly sent Major Claude Macdonald to inquire into the matter He was accompanied by Captain Mockler-Ferryman, who in the present volume gives a full account of the proceedings of the Mission During the entire journey, which extended over more than 3000 miles, nothing "of a blood-curdling nature" occurred, so that any one who is attracted to books of travel mainly by the chance of finding them full of sensational narratives, need not trouble himself with Captain Mockler-Ferryman's pages On the other hand, those who like to read about remote regions and their native inhabitants, will find in this book much to interest them The author is an accurate observer, and notes in a clear and unpretending style the facts by which his attention has been most strongly attracted His descriptions of the native tribes of the Niger country, so far as he himself observed them, are particularly good, and will not only please the general reader, but be of service to ethnologists and anthropologists A capital chapter on music and musical instruments, prepared from materials collected by the members of the mission, is contributed by Captain C R Day, and the value of the volume as a whole is much increased by a map and illustrations

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications*]

Density of Nitrogen

I AM much puzzled by some recent results as to the density of *nitrogen*, and shall be obliged if any of your chemical readers can offer suggestions as to the cause According to two methods of preparation I obtain quite distinct values The relative difference, amounting to about $\frac{1}{1000}$ part, is small in itself, but it lies entirely outside the errors of experiment, and can only be attributed to a variation in the character of the gas

In the first method the oxygen of atmospheric air is removed in the ordinary way by metallic copper, itself reduced by hydrogen from the oxide The air, freed from CO_2 by potash, gives up its oxygen to copper heated in hard glass over a large Bunsen, and *then* passes over about a foot of red hot copper in a furnace This tube was used merely as an indicator, and the copper in it remained bright throughout The gas then passed through a wash bottle containing sulphuric acid, thence again through the furnace over *copper oxide*, and finally over sulphuric acid, potash, and phosphoric anhydride

In the second method of preparation, suggested to me by Prof Ramsay, everything remained unchanged, except that the *first* tube of hot copper was replaced by a wash-bottle containing liquid *ammonia*, through which the air was allowed to bubble The ammonia method is very convenient, but the nitrogen obtained by means of it was $\frac{1}{1000}$ part *lighter* than the nitrogen of the first method. The question is, to what is the discrepancy due?

The first nitrogen would be too heavy, if it contained residual oxygen. But on this hypothesis something like 1 per cent would be required. I could detect none whatever by means of alkaline pyrogallate. It may be remarked the density of this nitrogen agrees closely with that recently obtained by Leduc, using the same method of preparation.

On the other hand, can the ammonia-made nitrogen be too light from the presence of impurity? There are not many gases lighter than nitrogen and the absence of hydrogen, ammonia, and water seems to be fully secured. On the whole it seemed the more probable supposition that the impurity was hydrogen, which in this degree of dilution escaped the action of the copper oxide. But a special experiment appears to exclude this explanation.

Into nitrogen prepared by the first method, but before its passage into the furnace tubes, one or two thousandths by volume of hydrogen were introduced. To effect this in a uniform manner the gas was made to bubble through a small hydrogen generator, which could be set in action under its own electromotive force by closing an external contact. The rate of hydrogen production was determined by a suitable galvanometer enclosed in the circuit. But the introduction of hydrogen had not the smallest effect upon the density, showing that the copper oxide was capable of performing the part desired of it.

Is it possible that the difference is independent of impurity, the nitrogen itself being to some extent in a different (dissociated) state?

I ought to have mentioned that during the fillings of the globe, the rate of passage of gas was very uniform, and about ½ litre per hour.

Recent Spectroscopic Determinations

IN the September number of the *Philosophical Magazine* Mr. Michelson has published determinations, by a most interesting method, of very close double and multiple lines. In any attempt to interpret his results, it is necessary to bear in mind the profound modifications which the internal motions of a gas—the rectilinear motions of the molecules between their encounters, as well as the motions going on within each molecule—had undergone within the Geisler's tubes upon which he experimented.

In a gas under ordinary circumstances the rectilinear journeys of the molecules take place indifferently in all directions, and where this is the case it follows from the well known relation between the surface of a sphere and that of its circumscribing cylinder, that the effect of the velocities which happen to lie between ν and $\nu + \delta\nu$ is to substitute for each line of the spectrum of the gas a band of uniform intensity and without nebulous edges, the width of which can be calculated. This width, for example, is .04 of an Angstrom or Rowland unit (the tenthet metre), in the yellow part of the spectrum and for velocities of the molecules which lie in the neighbourhood of two kilometres per second, which is about the average velocity of molecules of hydrogen at atmospheric temperatures. Hence with all the velocities that prevail among the molecules, the effect of the rectilinear motions under ordinary circumstances is that each line will be symmetrically widened and rendered nebulous. To this effect Mr. Michelson calls attention.

But in the residual gas of a Geisler's tube through which electricity is passing, the case is altogether different. Here the rectilinear motions of the molecules are not alike in all directions, but preponderate in some: a state of things which must at least double the lines, and may introduce greater complications.

Moreover, different lines may be differently affected, since the behaviour of the gas varies according to its position between the electrodes, as is evidenced by the observed differences in the form and colouring of the striæ, &c., in the several parts of a Geisler's tube.

We must also be on our guard in another respect, when we attempt to interpret the results, since the distribution of the heat energy of a gas between the rectilinear motions of its molecules and the motions within the molecules, which in the case of ordinary gas is a fixed ratio, is certainly largely departed from in gas through which electricity is passing. Until the laws of the new distribution are understood, the temperature of the gas, judged of by its behaviour to neighbouring bodies, will give us little information.

It is to such events as are referred to above, or others which like them may arise from the special circumstances under which the vapour of sodium was in Mr. Michelson's experiments, that we must apparently turn for an explanation of the doubling of the constituents of the principal pair of sodium lines which he has detected; since he found that "the width of the lines, their distances apart, and their relative intensities vary rapidly with changes in temperature and pressure."

The method of investigation which Mr. Michelson has so successfully applied appears to be by far the most searching means yet discovered of experimentally investigating the intricate and obscure phenomena which present themselves in Geisler's tubes, and we seem justified in hoping for great results from it.

9, Palmerston Park, Dublin, September 22

Printing Mathematical Symbols

EVERYONE who has had to correct printers' proofs of mathematical formulæ must be painfully alive to the pitfalls into which the non-mathematical compositor continually blunders. To such as know the extreme difficulty of getting such formulæ properly set up, there have doubtless occurred from time to time suggestions for such simplifications of notation as shall render the composition less liable to derangement. One most sensible step of the kind I allude to is the introduction by Sir G. Stokes of the solidus notation for quotients, whereby

$$\frac{dy}{dx} \text{ is now written } dy/dx$$

The immediate purpose of this letter is not to propound any wholesale scheme of reform, but to advocate one other simple step, and to induce some of my *confrères* to give the world their own suggestions.

Exponentials are a continual stumbling-block to the compositor, and to the printer's reader, who, when he comes to an expression like

$$A\epsilon^{-ax},$$

does his best to make it look a little straighter and turns it into

$$A\epsilon - ax,$$

or into

$$A_\epsilon - ax,$$

or perhaps worse.

The reform I advocate is to write the thing as follows:—

$$A \exp[-ax],$$

the square brackets being possibly omitted in all cases when their omission would occasion no confusion. One gain in this notation is the reduction of the whole of the symbols to one level, so not breaking the line of type.

Another useful reform, though one on which I fear the probability of agreement is less likely, is the use of the Continental notation for inverse trigonometrical functions, writing, for example,

$$\text{arc tan } x,$$

instead of

$$\tan^{-1} x$$

for the angle whose tangent is x. Our notation is not only liable to continual misprinting, but is very confusing to Continental readers, who again and again read the latter expression as meaning

$$(\tan x)^{-1}, \text{ or cotan } x$$

I have even seen it reprinted in a German technical journal as

$$\tan - 1x$$

A so-called Thunderbolt

DURING a short storm in Liverpool this summer, I noticed one flash as peculiarly sharp and noisy, and subsequently in the correct bearing from my house the ground was reported as having been struck by a thunderbolt. I examined the place, which was on the greensward of a lake, where the ground was penetrated by a number of fairly clean cut almost vertical holes down which a walking-stick could be thrust. People sheltering near the lake reported a ball of fire and a great splash up of the

water The odd circumstance about the damage was that it occurred on a simple grass slope, about half way between a tall boat house on the one side and a drinking fountain standing on more elevated ground on the other Small trees also were in the neighbourhood, and there was no apparent cause why the flash should have selected this particular spot, though indeed it was not within any of the ordinarily accepted "areas of protection" A gentleman—Mr Hewitt—proposed digging for the meteor, and although fairly convinced that it was nothing but an ordinary flash, we thought it just possible that an accidental meteorite might have fallen during the thunderstorm, in which event a flash down the rarefied air of its trail would be a natural consequence It may be just possible that the popular belief in thunderbolts has some such foundation

At any rate the excavation was made, with the result of proving that it was an ordinary flash and that the lightning made use of a surface drain pipe, about four feet deep, to get at the water of the lake

I enclose Mr Hewitt's report OLIVER J LODGE

DURING a thunderstorm on the afternoon of Sunday, July 3, 1892, what is described as a "ball of fire" was seen by several persons to descend to the ground, near the south end of the lake in Sefton Park, and immediately afterwards a column of water, about sixty feet high, was shot up from the lake On examining the spot where the ball of fire was seen to descend, several clean cut holes were observed, and a sod was also found at a little distance from the spot.

A few days afterwards an excavation was carefully made The sod being removed, the holes were traced down to a surface drain pipe four feet below the surface At this drain the holes terminated, and the pipe was found shattered The important holes were found to be six, the largest being seven inches in diameter, the others about two inches No meteoric matter was found, but it seems curious that this effect was brought about by a flash of lightning only in an open space of sloping grass, when there were trees and houses close by

Aigburth, Liverpool GEORGE H HEWITT

Peripatus Re-discovered in Jamaica

MRS E M SWAINSON has been so fortunate as to find on Beacon Hill, near Bath, three specimens of *Peripatus*, which she has sent to the Institute of Jamaica The species is doubtless identical with that found by Gosse many years ago at the other end of the island Of the two specimens which we have studied, one has 36 pairs of legs, and is dark pinkish-brown, with the ends of the antennæ pure white, in striking contrast, the other is smaller and darker, without white ends to the antennæ, and with only 29 pairs of legs The third example, which we have still alive, is larger, but dark in colour Full details will be given elsewhere later on, and it may suffice for the present to state that the species is very closely allied to *P Edwardsii* from Venezuela, as described by Sedgwick, but differs in the greater number of legs and the white tipped antennæ of certain individuals (probably the females), in the only slightly curved (not hooked) claws, in the differentiation of the papillæ into two distinct kinds on the dorsal surface, and apparently in other minor matters There is no dark dorsal line The genital orifice is between the penultimate pair of legs, and the jaws are almost precisely as in *Edwardsii* The Jamaican species being evidently new, it is proposed to call it *Peripatus jamaicensis*

Reflection on Valley Fog

A LETTER from an observer at the Lick Observatory appeared in NATURE on August 25, reporting the reflection of mountains in a valley fog I was therefore much interested to note the following in the *Yorkshire Herald* of September 7 —

"SIR,—Possibly it may interest your readers to hear of a natural phenomenon I noticed this morning before 6 a m Overlooking, from Leyburn, the valley of Wensleydale, it appeared as though more than half of the dale was filled with water, like a great lake with rising hills on either side, and these hill-sides, above the level of the (apparent) flood, were distinctly reflected in it The sun was shining brightly at the time, but almost immediately the mist began to disperse, and the mirage faded away What struck me as unusual was the extraordinary distinctness of the reflection Yours, AN EARLY RISER September 5, 1892"

In both cases the reflecting film seems to have been near its vanishing point J EDMUND CLARK

Impure Water in Bread

SOME accurate answers to the following questions would be desirable, in view of public health

(1) What bacilli—if any—can survive in the amount and duration of the heat of baking in the interior of unfermented bread?

(2) What is the further effect of the carbonic acid of fermentation?

(3) What is the effect of the water being highly carbonated without fermentation, as in aerated bread?

W M I P

The Comets of Brorsen (1846 VII) and Brooks (1892 "d")

THE elements of Brooks's comet "1892 *d*," as computed by Berberich from four observations made between August 31 and September 5, bear a strong resemblance to those of Brorsen's comet of 1846, calculated by Oudemans, the figures being —

	Comet Brorsen (1846 VII)	Comet Brooks (1892 *d*)
T	1846 June 5 479	1892 Dec 19 727
	° ′ ″	° ′ ″
ω	260 12 50	269 24 27
☊	261 53 12	261 2 55
i	29 18 17	27 57 8
Log q	9 80188	9 84455

Brorsen's comet of 1846 was visible to the naked eye on May 14 of that year It was supposed to be revolving in an elliptical orbit, with a period of about 400 years W F DENNING

Bristol, September 22

NOTE ON THE PROGRESS OF THE DIOPTRIC LENS AS USED IN LIGHTHOUSE ILLUMINATION

FRESNEL, in 1820, devised and constructed a lens for first order lights of 920 mm radius It was composed of a plano convex lens, with five refracting prisms concentric with it, and four segments of rings in the corners all gradually decreasing in breadth as they receded from the centre The separate pieces of which these lenses were made up were cemented together and mounted in metallic frames 30 inches square

In 1835, the late Mr Alan Stevenson introduced the French apparatus into Great Britain In doing so he made several improvements, one of which was that he increased the height of the lens from 30 to 39 inches, at the same time diminishing the thickness of the glass This refractor had eight prisms above and eight prisms below the central lens From that time Alan Stevenson's lens was almost universally used until a comparatively recent date, when a revolution in the size of lenses took place

A few years ago inventors were trying to obtain greater power by increasing the diameter and volume of the flames, but Messrs Stevenson pointed out, in 1869, that after a certain point an increase of diameter of the luminary not accompanied by a corresponding increase of the radius of the apparatus was a mistake, as the light became ex-focal and divergent, and that the proper way to secure greater power was to enlarge the *diameter* of the apparatus In 1885 they had a lens made to their design of 1330 mm radius, and having a height of 5 feet This lens, which was named "Hyper-radiant," was tried at the South Foreland against other lenses, and with a large 10-ring gas burner it was found to give a light from one and a half to twice as intense as the ordinary lenses which were pitted against it, with the same large burners in their foci, thus proving conclusively that to get the power out of large burners it was imperatively necessary

to increase the diameter of the apparatus. In 1883 Messrs. Stevenson got an offer from Messrs. Barbier for a lens of 1840 mm. focal distance.

All refracting lenses from the day of Alan Stevenson were cylindrical for fixed lights and plano-convex for revolving lights, and no alteration of any moment has been made in the mode of their construction until 1888, when, instead of making the lenses cylindrical or plano-convex, I proposed to give them a spherical form, that is to say, circular not only in the horizontal but also in the vertical section. This design was carried into practice in the apparatus for one of the Fair Isle Lighthouses. The introduction of the spherical refractor has made practicable the construction of very much larger and consequently more powerful apparatus, and occupying much less space both in the daylight size and diameter of lantern, and, hence, diameter of tower. It has rendered practicable the quadrilateral arrangement with hyper radiant lenses which have already been erected at Fair Isle, the lenses being cut so as to give two flashes from each side of the quadrilateral. An experimental lens made for Mr. Wigham is to be tried in Ireland. It is 2m. focal distance, and the spherical refractor is 7 feet 6 inches diameter, and will give one flash from each side of the quadrilateral. M. Barbier says that in making this lens he was attempting to give the most powerful flash possible, and he adopted the spherical refractor. In this case, however, the spherical refractor has been carried, in my opinion, rather far, except in the view of economy in keeping the angles of the whole apparatus within reasonable limits, which is only possible (in an apparatus of 4m. diameter) by the use of the spherical refractor, and by its being made to subtend a great angle. When I proposed this form I pointed out that there was a loss of efficiency if it subtended more than 40°, now M. Barbier has made the spherical portion subtend 64°, or 24° farther, and 8° farther than any spherical refractor yet made. The great amount of light which I experimentally found re-

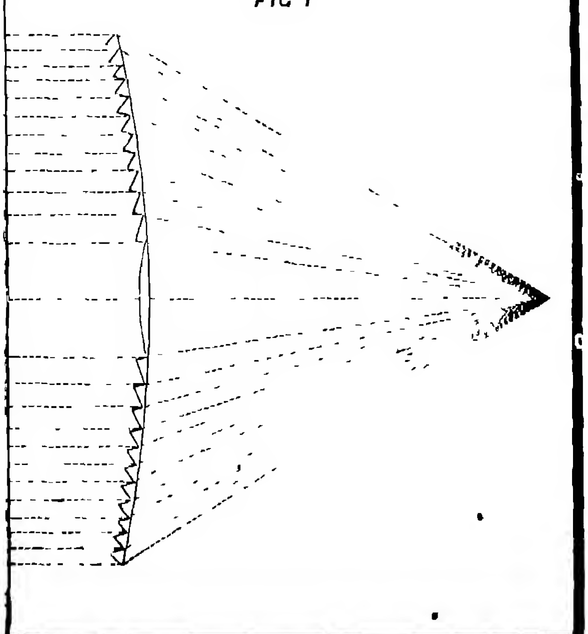

FIG. 1.

turned from the inner face of the spherical refractor made for Fair Isle, however, shows that up to 20°, and perhaps farther, it is ample to make up for any loss of light caused by the greater divergence which takes place *in* the spherical refractor, and which would be a *small* source of loss in a revolving light, but would better illuminate the nearer sea in a fixed arc.

Equiangular Refractor.

To obviate the loss of light at the outer face of the lenses, especially those remote from the focal plane—a

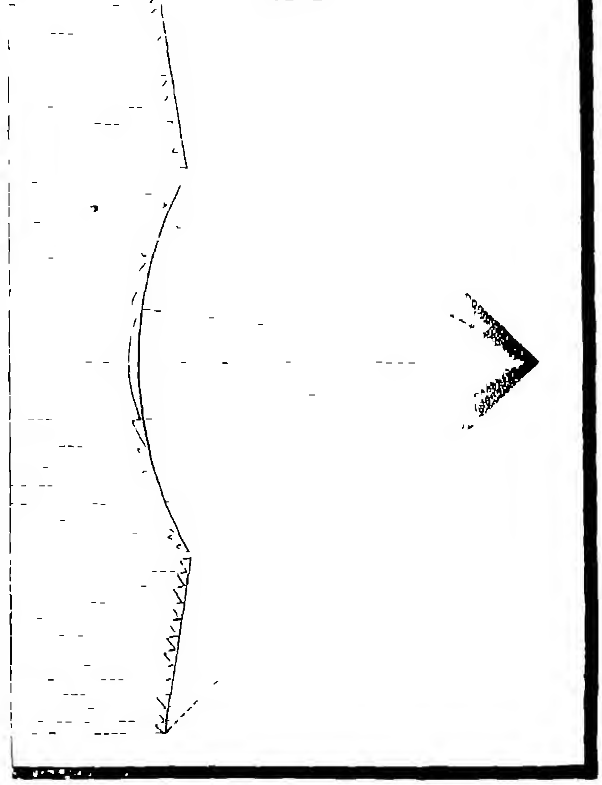

FIG. 2.

loss which stops the refractor being carried with due regard to efficiency farther than 30° to 40° in the cylindrical form, and 20° in the spherical form—it will be found that the most efficient form is a refractor which I proposed, with the inner face of each lens doing equal work with the outer face, or nearly so—and by a careful study of such a refractor it will be found that the locus of the centres of curvature of each refracting lens lies outside the refractor, and at points below the focal plane, and more and more remote from the lens, as the lenses are more and more remote from the focal plane, and that the inner face of the refractor ought, in fact, to be a parabolic curve (Fig. 1). This can very closely be approximated to by a circular curve with a suitably chosen centre on the focal line produced, but the centre is so far distant that when the spherical form and the equiangular form are used in combination (Fig. 2), the inner face of the equiangular prisms above and below it may, with sufficient accuracy, be made straight and leaning outwards in place of being vertical as in Fresnel's form. By the combination of the spherical refractor and the equiangular, or a refractor of the equiangular form alone, the defect in Fresnel's refractor, namely the loss of light at emergence from the lenses, especially those remote from the focal plane, is avoided, and the refractor may thus be made to subtend an angle which has hitherto been considered inexpedient, with glass of the ordinary

refractive index of 1 53 The equiangular prisms cause less loss of light by absorption and reflection than either the spherical or Fresnel refractors, and also act on the light so that ex-focal light is better dealt with, thereby reducing the divergence

CHARLES A STEVENSON

MODERN DYNAMICAL METHODS

A DYNAMICAL system is said to possess a *given* number of degrees of freedom, when it is capable of assuming the *same* number of independent positions The position of the system, in any possible configuration, is capable of being determined by a definite number of independent quantities, which are equal to the number of degrees of freedom of the system These quantities are called the co-ordinates of the system

When the system possesses six degrees of freedom, the motion may be completely determined by expressing in mathematical language a principle which may be conveniently termed the *principle of momentum* This principle is specified by the following two propositions — (i) *The rate of change of the component of the linear momentum, parallel to an axis, of any dynamical system, is equal to the component, parallel to that axis, of the impressed forces which act upon the system*, (ii) *the rate of change of the component of the angular momentum about any axis, is equal to the moment of the impressed forces about that axis* Since the motion of the system may be referred to any set of fixed or moving rectangular axes, the above-mentioned dynamical principle furnishes six equations connecting the six co-ordinates, which, when integrated, will determine the latter in terms of the time and the initial circumstances of the motion

The various ways of expressing this dynamical principle in mathematical language are explained in treatises on dynamics and a variety of special forms and particular cases are obtained, by means of which the solution of numerous problems can be simplified For example, Euler's equations, for determining the motion of rotation of a single rigid body about its centre of inertia, is a particular case of the second proposition, whilst Kirchhoff's equations, for determining the motion of a single solid in an infinite liquid, is a special form of both propositions

When a conservative system possesses seven degrees of freedom, the motion may be completely determined by means of the principle of momentum combined with the principle of energy The first principle, as we have already shown, furnishes six equations, whilst the second furnishes one, hence, we have a sufficient number of equations for determining the motion

When a dynamical system possesses more than seven degrees of freedom, the principles of momentum and energy are insufficient to determine the motion, and under these circumstances, the most convenient method to adopt is to use Lagrange's equations, but inasmuch as these equations are double-edged tools, which are apt to cut the fingers of the unwary, their employment requires considerable care

The kinetic energy of a dynamical system can be expressed in a variety of different forms, but it will only be necessary to mention the following three In the first form, it is expressed as a homogeneous quadratic function of velocities, which are the time variations of the co-ordinates of the system This form, which will be denoted by T, is called the *Lagrangian form*, it is the only one which it is permissible to use when employing Lagrange's equations, and many mistakes have been made by persons who have attempted to use some other form.

In the second form, which is called the *Hamiltonian form*, the kinetic energy is expressed as a homogeneous quadratic function of the momenta of the system If θ be any co-ordinate, and Θ the generalized momentum of type θ, it is known that

$$\frac{\partial T}{\partial \dot\theta} = \Theta \qquad (1)$$

whence Θ is a linear function of the velocities Hence, if the velocities be eliminated from the Lagrangian expression for the kinetic energy by means of (1), it follows that the latter will be expressible as a homogeneous quadratic function of the momenta Θ, which is the Hamiltonian form We shall denote this form by $\mathfrak{T}$

Lagrange's equations are

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot\theta}\right) - \frac{\partial T}{\partial \theta} = - \frac{\partial V}{\partial \theta} \qquad (2)$$

where V is the potential energy, and if the elimination be performed, we shall obtain

$$\frac{d\Theta}{dt} + \frac{\partial \mathfrak{T}}{\partial \theta} = - \frac{\partial V}{\partial \theta} \qquad (3)$$

we have also the reciprocal relation

$$\frac{\partial \mathfrak{T}}{\partial \Theta} = \dot\theta \qquad (4)$$

Equations (3) and (4) are Hamilton's equations of motion

The third form of the expression for the kinetic energy is of special importance in hydrodynamics and other branches of physics It sometimes happens that a quantity occurs which can be recognized as a momentum, or as a quantity in the nature of a momentum, whilst the velocity corresponding to this momentum is either unknown or would be inconvenient to introduce This occurs in problems relating to the motion of perforated solids in a liquid, when there is circulation, and is a particular case of Dr Routh's theory of the "Ignoration of Velocities"[1] We therefore require a form of Lagrange's equations in which certain velocities are eliminated, and are replaced by the corresponding momenta

Let the co-ordinates of the system be divided into two groups, θ and χ, and let κ denote the generalized momentum corresponding to χ Then

$$\frac{\partial T}{\partial \dot\chi} = \kappa \qquad (5)$$

By means of (5) all the velocities $\dot\chi$ can be eliminated from the expression for the kinetic energy, and it is remarkable, that the result of the elimination does not contain any products of the form $\kappa\dot\theta$ The expression for T may accordingly be written

$$T = \mathfrak{T} + \mathfrak{K} \qquad (6)$$

where $\mathfrak{T}$ is a homogeneous quadratic function of the velocities $\dot\theta$, and $\mathfrak{K}$ is a similar function of the momenta κ

Equation (6) is therefore a mixed form, which is partly Lagrangian and partly Hamiltonian We now require the corresponding form of the equations of motion in which all the χ's have been eliminated from Lagrange's equations

From (1) it follows that the generalized momentum Θ is a linear function of the velocities $\dot\theta$, $\dot\chi$, and if the latter velocities be eliminated by means of (5), it follows that Θ is expressible as a linear function of $\dot\theta$, κ Let the portion which is a linear function of the κ's be denoted by $\bar\Theta$, then it can be shown, that if

$$L = \mathfrak{T} + \Sigma(\bar\Theta\dot\theta) - \mathfrak{K} - V \qquad (7)$$

the equation of type θ is

$$\frac{d}{dt}\frac{\partial L}{\partial \dot\theta} - \frac{\partial L}{\partial \theta} = 0 \qquad (8)$$

[1] Having regard to the object of the theory, I think the phrase "Ignoration of Velocities" is better than "Ignoration of Co-ordinates."

whilst that of type χ is

$$\frac{d\kappa}{dt} - \frac{\partial \mathfrak{I}}{\partial \chi} = 0 \tag{9}$$

We have also the additional equations

$$0 = \frac{\partial \mathfrak{T}}{\partial \theta} + \Theta \tag{10}$$

$$\chi = \frac{\partial \mathfrak{K}}{\partial \kappa} - \Sigma\left(\theta \frac{\partial \Theta}{\partial \kappa} \right) \tag{11}$$

Equations (7) to (11) were first given by myself in a paper published in the Proc Camb Phil Soc for 1887, and it will be observed that they include the equations of Lagrange and Hamilton A form of the modified Lagrangian function, which is equivalent to (7), was given by Dr Routh a few years previously, but it is not of much practical use, owing to the fact that the elimination of the velocities χ has not been performed

It sometimes happens that the *co-ordinates* of the type χ do not enter into the expression for the energy of the system, in which case they are called *ignored co-ordinates*,[1] under these circumstances it follows from (9), that all the momenta κ are absolute currents A top spinning about its point under the action of gravity is one of the most familiar examples of ignored co-ordinates, and one which illustrates several important dynamical theorems

When there are ignored co ordinates, the steady motion of the system, and the stability of the steady motion, can very easily be investigated For if we suppose that all the co-ordinates θ have constant values, (8) reduces to

$$\frac{\partial \mathfrak{K}}{\partial \theta} + \frac{\partial V}{\partial \theta} = 0$$

There are as many equations of this type as there are co ordinates θ, and an examination of this system of equations will show whether steady motion is possible, and if so, will determine the necessary conditions which the co ordinates θ and the constant momenta κ must satisfy

It can also be shown that the steady motion will always be stable when $\mathfrak{K} + V$ is a minimum (see Proc Camb Phil Soc May 1892)

We have therefore the following simple rule for determining the steady motion of a dynamical system when there are ignored co-ordinates Eliminate all the velocities corresponding to these co ordinates from the expression for the kinetic energy of the system, so that the latter is expressed in terms of the velocities $\dot\theta$ and the momenta κ Let $\mathfrak{K}$ and V be that portion of the *total* energy which does not depend upon the $\dot\theta$'s, then the conditions of steady motion are, that $\mathfrak{K} + V$ should be stationary, and the steady motion will be stable provided this quantity is a minimum

The preceding theorem also enables us to deduce by a very concise method all the results connected with the steady motion of a liquid ellipsoid, which is rotating about a principal axis under the influence of its own attraction It also enables us to examine the stability of these different cases of steady motion, for disturbances which produce an ellipsoidal displacement

A B BASSET

THE PASSAGE OF GRANITE ROCK INTO FERTILE SOIL

HAVING for the last three or four years paid particular attention to the natural formation of soil, I venture to believe that a concise account, or rather summing up, of the results of my researches, and of the mass of my observations—in one typical direction—may be of interest to the readers of NATURE As indicated in the heading, the making of soil from granite is the only section of a very large subject which will be briefly considered in this paper

The agents concerned with the turning of granite (or any other rock) into a fertile soil may be shortly classified as mechanical, chemical, and vital The first-named produce the largest results in bulk, and the principal mechanical agent with which we have to deal is frost The second and third classes of forces are extremely important, as it is by their actions that the raw material of plant-food is prepared, though unfortunately poisons also are brought into being through their activity These last named classes, however, likewise materially aid the action of frost (or, in tropical countries of varying temperatures) in the mechanical separation of rocky matter To render my descriptions as little confusing as possible I will endeavour, without regard to classification, order, or divisions, to trace the history of a granite soil as I have observed it in many localities in Scotland, from the practically unbroken rock into the condition in which it has been made by nature fit to bear the most luxuriant crops But first of all I must remind my readers of two or three geological facts about granite It is a holocrystalline (*i e* wholly crystalline) igneous rock, composed essentially of orthoclase, quartz, and mica In its most typical condition the last-named mineral is always of the biotite or magnesia-mica species Besides these essentials we always find (in Scotch granites at least) plagioclase, other species of mica than the essential, apatite as an endomorph, *i e* locked up in the mass of other minerals, and magnetite, and almost invariably, if not always, a little pyrites, and more or less hornblende, &c

A rough mineralogical analysis of Kemnay granite taken from the lowest working of the well-known quarry in Aberdeenshire gave the following percentages —

Orthoclase felspar	42 00
Quartz	22 00
Biotite-mica	20 00
Plagioclase felspar	9 00
Hornblende	3 25
Muscovite mica	2 00
Magnetite (and Ilmenite)	1 00
Pyrites	0 50
Apatite	0 25
Total	100 00

The first change which comes over granite is the peroxidation of some of the iron always present in its mass This sets in, and increases to the greatest extent, of course, where air and water can most readily enter The surface of the rock becomes browned with the hydrated ferric oxide formed, and brown skins, of a deeper colour than the surface generally, coat the walls of the original rock joints But in the mass of the rock, away from these primary fissures, there are areas which are more permeable than others from the surface, and through these, streaks of ferric oxide—anhydrous first, afterwards hydrated—are produced Those lines of rust are the beginnings of a new set of joints, which have not yet been properly recognized in geological literature, and which I will here call weather joints to distinguish them from the primary joints of consolidation and rock movements. The first oxidation streaks of the coming weather fissures are invisible to the eye, but can be determined under the microscope They gradually increase in width above as they extend their lines beneath, and they afford passages through which water can more readily percolate than in the surrounding fresher areas, and as a consequence planes along which frost can more powerfully act By

[1] I must confess that I do not like the phrase *speed co-ordinates*, introduced by Prof. J J Thomson, for it conveys absolutely no meaning to my mind. I have no sympathy with the attempts, which have occasionally been made, to introduce short words of Teutonic origin into scientific nomenclature, as the words in question appear to me to be singularly deficient in point.

the constant multiplying of the weather joints, which are first marked out by oxidation as already indicated, and afterwards made definite and widened from the most exposed rock surface inwards by frost, one of the first steps in soil formation is accomplished. As those fissures are increased the uppermost portion of the rock is separated by them into distinct pieces, which latter are again in their turn broken up by the formation of weather joints in the same way as the original. The great bulk of a soil has been produced in this way.

While the oxidation of the iron, as I have observed, is very likely the first change to set in in every case, it is never left for any lengthened period to promote, by itself alone, the decomposition of the rock. Very soon the work of carbonation is seen to be progressing alongside of it, though at a considerably slower rate. The carbonic acid gas of moist air, dissolved in the penetrating water, attacks the felspars, the biotite, and the hornblende. The way in which it brings about the decomposition of these minerals is interesting. Certain molecules succumb much more easily to the action of the carbonic acid than others, and the result is that scattered points of weakness from the thorough decomposition of these are brought into being in different parts of the mineral, and those decomposed portions warp round about the other and fresher molecules, as shown in the annexed diagram, which has been constructed from what I have observed in decomposed felspars.

The clay of decomposed felspar has great plastic and warping power. I have observed only 15 per cent of pure clay in a mass hold the 85 per cent of other and different constituents together in a plastic union as if the whole had been pure clay. There are two or three other hitherto unknown facts connected with the natural decay of felspars which I have ascertained from my re-

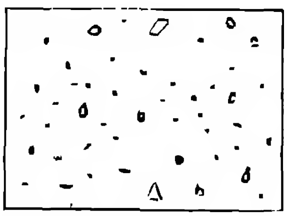

Diagram of kaolinized felspar × 260. The whole ground mass is kaolin or pure clay; the bodies scattered through this are parts of the original felspar not yet decomposed.

searches. I have noted two processes of decomposition—that which occurs when the carbonic acid is in excess or can obtain free access to the mineral, and that which takes place when either of the opposite conditions prevails. In the first case the felspar—supposing it to be *orthoclase*—has the molecules of its body which are affected completely broken up into clay, solid secondary or colloid silica, and carbonate of potash. In the second case, where for some reason a sufficient supply of carbonic acid cannot get within "chemical" distance of the felspar molecules, clay is produced as before—only more slowly—but the potash of the molecule is carried off in two sections, part as a carbonate, and part as a soluble silicate.[1] From the *plagioclase*-felspar the same conditions produce similar results, except that the soluble silica which would be produced here is of course in combination with sodium. I have found the soluble silica of soils *always* in the form either of silicate of potassium or sodium, and very frequently both of these occur mixed together.

Biotite, by the continued action of carbonic acid, oxygen, and water, loses magnesia (taken out as carbonate) and iron (removed either as oxide or carbonate) and becomes eventually the white or yellow muscovite variety which undergoes no further chemical change. In biotite, however, the chemical change usually takes place much more uniformly through the mineral body than ever happens in the case of the felspars.

Hornblende by carbonation, oxidation, and hydration yields lime as carbonate until the whole of that base is taken out, a trace of magnesia as carbonate (the bulk of this base is almost invariably left in the insoluble residue), the chief portion perhaps of its iron as oxide and carbonate, manganese as hydrated oxide, and any trace of sodium and potassium which it may contain as carbonates, or partially when conditions are less favourable as soluble silicates. The residue left after the hornblende has lost the above can generally be determined as some variety of chlorite (hydrated silicate of magnesia, iron, and alumina), which in the course of time by further loss of iron becomes an impure serpentine, and this later on a steatite or magnesia clay, to which the greasy feel of soils is due.

The *pyrites* of the granite rock is slow to change, but it also is eventually acted on, by water and oxygen particularly, the latter combining with its substance here and there to form a sulphate, which has a great mission in the physiology of the soil.

I have said that the *apatite* occurs as an endomorph. It is set free to dissolve slowly without change in ordinary carbonated water when the minerals which hold its microscopic needles in their substance are broken up, mechanically or chemically. The *magnetite* and *ilmenite* grains of the granite rock are only altered with provoking slowness. Their function, however, in the work of the soil is, as far as I can see yet, of no importance. Traces at least of another mineral occur very frequently in granites. This is tourmaline, the history of which in soils I have been investigating for the last half-a-dozen years with some success.

The chemical changes which I have been mentioning begin first on the exposed surfaces of the rock and along the faces of the primary joints. Then oxidation occurs in streaks and bands through the rock mass, and around those areas carbonation is most active. In fact oxidation opens up the rock for further change, chemical as well as mechanical.

Frost is the principal agent of disintegration or mechanical breaking up in this country, but a relatively minute portion of the work is accomplished by heat and cold, the friction of percolating water, changes in the degree of humidity of the atmosphere, the pressure exerted by roots, and so on.

No sooner does a fraction of the surface percentage of the exposed rock portion undergo chemical change than a new element in the making of soil comes into play—that, namely, of organic matter, first living, and then dead and living. We will deal first with the living matter. On the partially decomposed surface of rock, fungal and algal spores (the latter of a lowly type) settle and live and grow in symbiotic union as lichens. There are many different kinds of rock-lichens, but the vegetative physiology of all is identical. The surface of the growth which lies next the stone is engaged in parts, during moist weather at least, in the imbibition of water, with the exceedingly meagre amounts of mineral matters dissolved in it from the surface of the rock. Those absorbing areas of the under surface appear to be also superficial breathing organs, for they certainly excrete carbonic acid gas, which of course will join with the atmospheric carbonic acid in helping the work of decomposition of mineral bodies. And it appears to me—though here I am not certain—that these absorbing areas are less generally found over the quartz of the granite, which is not capable of chemical change, than over the decomposable minerals. The lower absorbing areas of the lichens are in their functional relations common to internal fungal and algal

[1] See also in this connection my article on "The Action of Lime on Clay Soils," NATURE, Jan. 29, 1890.

members, and the upper surface of the colony is also a common absorbing (and transpiring) tissue, though here it is only the atmosphere gases which are taken in to the interior There is not the slightest doubt but that the fungal members utilize the nitrogen of the air, there is none in the rock for them to receive, and that the algal members absorb carbonic acid gas from the air taken in, and combine it with the elements of water to make carbonaceous food, for that again is not presented to them from the rock, the lichen growth cannot any more than is the case with higher plants utilize the carbon of the mineral carbonates in the manufacture of carbohydrate or hydrocarbon food

In reproduction, separate spores of algæ and fungi are produced from the lichen, and some of these may germinate above the parent community and unite to form a fresh colony upon the old, or a new colony may be produced from foreign spores In any case we find generation after generation of lichens forming on the same favourable spot, but succeeding generations are partially parasitic and saprophytic in nature, as is shown by the manner in which their lower absorbing surfaces or prolongations act on the lichen growths beneath them By and by, when perhaps a score of lichen colonies have formed one above the other—the newer slowly extinguishing the life of the older—a vegetable considerably higher in the scale of being comes forward and caps the last lichen This is some variety of moss Spores of mosses, carried to the stone surface, germinate there in moisture, and if upon lichens, the moss plantlet develops into the adult Its rhizoids pierce their way through the substance of the lichens, and many get down to the decomposing stone surface, while some never leave the lichen bodies The action of the moss rhizoids on living and dead lichens, also, I think, shows that that plant can be a parasite and a saprophyte as well as a normal vegetable feeder, and in this respect, except in its not utilizing the nitrogen of the air, resembles the later lichen growths

In this way, by the succession of lichens and mosses (and afterwards higher plants), the essential organic element of soils becomes early incorporated with the mechanically and chemically disorganizing rock

The dead organic matter changes in different ways first, very slowly and very indifferently, by the action of air and water, and second, rapidly, by the spreading through its mass, where air has free access, of bacteria and other lowly fungi which are saprophytic, but can also assimilate nitrogen from the atmosphere, as is shown by their increasing, and not simply maintaining the original amounts of nitrogen left by their predecessors By the first method of change the organic matter becomes the tougher former of humus, and humic and other related acids arise from it, by the second the mild, dry, or friable humus is produced and little or no humic acid A very careful investigation shows that those bacteria which have the power of removing from the dead organic matter the elements of their nutrition give out by the decay (which occurs rapidly) of their bodies when they die the nitrogen and other elements in an active state The nitrogen of the dead bacteria forms readily nitrate of lime or potash by contact with these bases

Now to give a short summary here Oxidation of iron is the first change perceivable in granite, then creation and multiplication of weather joints, and carbonation follows, next humus is formed by lichens, and then higher plants, following this, fungoid germs, capable of assimilating aerial nitrogen, become abundant, finally all the three processes, mechanical, chemical, and organic, go merrily on together and contribute all in their proper shares to the formation of an ever-deepening soil, capable of supporting the luxuriant life of the highest plants The humic acid which is formed by the inorganic decay of humus has a certain decomposing action, but it gradually changes to carbonic acid, with the action of which, in this connection, we have already dealt Well, to apportion the shares of the work done further By disintegration or mechanical action, the great rough mass of the soil is produced By oxidation and carbonation, soluble minerals capable of entering the plant are prepared, and insoluble matters like secondary silica, pure clay, and steatite, are brought into being By the action of living matter, rock decomposition is hastened, and nitrogenous substance is brought into the soil By the presence and action of dead organic matter, rock decomposition is also forwarded, and a field for aerial nitrogen-assimilating germs is prepared The table below gives a list of the materials found in the youngest granite soil on which nothing higher than rock-mosses are growing

Granite minerals in fairly fresh condition	About 80 per cent
Clay and insoluble secondary silica	About 3 per cent
Soluble silica	Not determinable
Carbonates of potash, soda, lime, magnesia, iron, and phosphate of lime	About 2 per cent
Sulphates of above, except iron	Not determinable
Sulphate of iron	Merest trace
Peroxides of iron and manganese	About 3 per cent
Humus	12 per cent
Total	100 per cent

Later on, as the soil deepens, we find some curious changes proceeding, which I will briefly indicate Sulphates are now produced in considerable quantities Wherever iron-containing minerals are brought into contact with organic matter, sulphate of iron tends to form as well as carbonate (humate ?), and possibly other compounds, and the pyrites which was slow to change at the beginning now produces sulphate of iron with greater rapidity The dissolved sulphate of iron coming into contact with the carbonates of the alkalies and alkaline earths liberated from the felspars, hornblende, &c, as already explained, causes a double decomposition The ferrous sulphate becomes a carbonate, and the carbonates of lime, potash, soda, &c, become sulphates The iron carbonate, where exposed to air, readily oxidizes to ferric oxide, the chief colouring ingredient of the soil

Now, in the finished soil, which, it must be remembered, is when produced from granite a loam, we have the following approximate composition, as fairly typical of a good granite soil such as may be found in the valley of the Don in Aberdeenshire —

			Per cent
Insolubles	Pure clay and steatite	about	10
	Quartz and secondary silica	,,	20
	Muscovite	,,	4
Substances capable of transformation	Orthoclase	,,	30
	Plagioclase	,,	4
	Biotite	,,	9
	Magnetite ?	,,	0·5
	Hornblende	,,	2
	Hematite and limonite (ferric oxides) and manganic oxide	,,	9
	Pyrites	,,	0·5
	Humus and animal organic matter, fungi, &c	,,	5
Injurious solubles	Humic acid	,,	0·5
	Soluble silicate	,,	0·3
	Ferrous sulphate[1]	,,	0·5
Non-injurious solubles	Phosphates of lime, magnesia, potash, soda, &c	,,	0·3
	Sulphates of lime, potash, soda, magnesia, &c.	,,	0·8
	Nitrates of lime, potash, soda, magnesia, &c	,,	0·3
	Carbonates of lime, potash, soda, magnesia, &c	,,	0·1
	Chlorides of above	,,	Trace.
Water and air (mechanically held) in dry summer perhaps about		,,	3·2
	Total		100·0

[1] More than 0·1 per cent is injurious.

In conclusion I have to point out, as shown by my investigations commenced four years ago, that farmyard manure laid on to the land is only rendered properly available to the crops by the action of bacteria as indicated above in connection with the natural humus. The inorganic forces have little action upon it, except in producing humic acid and other injurious matters

The most of the soluble mineral substances in a mature soil, it may also be mentioned, are in the form of sulphate They originate from the primary minerals as carbonate, but are soon altered, mainly by the ferrous sulphate The sulphate unfortunately is not the most suitable form in which minerals can be presented to plants for absorption, for the simple reason that, being so stable in chemical union, it causes the loss of too much of the plant's energy in the interior of its body before it can be decomposed It must be remembered that green plants decompose the compounds which enter their system before they utilize their elements or simpler forms in the elaboration of food ALEXANDER JOHNSTONE

Edinburgh, August 5

THE IMPERIAL INSTITUTE AT ST PETERSBURG[1]

IN November, 1885, some months after the publication of Pasteur's discovery for the treatment of hydrophobia, an officer of the Russian Guards was bitten by a rabid dog This officer having been sent to Paris to undergo the treatment, his Highness Prince Alexander Petrowitch d'Oldenburg established, at his own expense, a provincial laboratory at St Petersburg, where Pasteur's treatment could be duly carried out This establishment, however, soon proved to be too small for scientific investigations to be properly carried out therein, and it was decided to build a large laboratory in which researches might be made under the best possible conditions, accordingly the same enlightened nobleman bought a piece of ground of 37,464 square metres in extent, on which the present Institute is built

The buildings comprise physiological, pathological, chemical, bacteriological, and epizootological sections, with their laboratories, under the direction of such men as Neucki, Winogradsky, and others There is also a department where Pasteur's treatment is carried out, together with a small hospital for infectious cases Each section is complete in itself, and all the arrangements are on the newest principles and on a very large scale The expenses are defrayed partly by the Prince of Oldenburg and partly by public subscription, and the whole Institute compares favourably with any Institute in France or Germany

The directors of the Institute publish every two or three months a volume embodying the scientific results obtained in the laboratories, and the first two numbers have now been published As might be expected after what has just been said, their contents are of wide and varied interest Neucki publishes some chemical researches on the microbe producing inflammation of the mammary glands of milch cows and goats, and his paper will specially interest those who in this country have followed the remarkable researches of Dr E Klein Winogradsky gives an account of the various nitrifying organisms discovered by him in the soil of different countries This author quotes the researches of Prof and Mrs. Frankland, and of Prof Warington, and though to some extent contradictory, Winogradsky's researches agree with those of the English observers in all essential particulars This paper is certainly the most important which has as yet appeared on this vexed question The results obtained by Pasteur's treatment in St Petersburg form the subject of a paper by Kraiouchkine, and it may be mentioned that the treatment appears to have been as successful at St Petersburg as in Paris

The other papers refer to the chemical and physiological effects of tuberculin (Bujwid, Helman), to the transformation of nutritive media by the bacillus of diphtheria, and to the chemical composition of this micro-organism (Dzierzgowski and Rekowski), while Blachstein endeavours to draw a distinction between the bacillus coli communis and the bacillus typhi abdominalis, based on the chemical decompositions produced by these organisms in the media in which they grow Lastly, Mizerski and L Neucki give a critical *résumé* of the methods used to estimate the quantity of hydrochloric acid contained in gastric juice

The researches which form the subjects of these papers are varied enough, and whilst congratulating their authors we may express the hope that the Institute will have a long and prosperous career Our good wishes must be tinged with regret for ourselves—regret that there should not be a similar Institute in England, and regret also that there should be in this country a class of people who will oppose the establishment of such an Institute until a Bishop or Royal Duke has died of rabies

M ARMAND RUFFER

NOTES

LAST week much anxiety was felt as to the health of Sir Richard Owen On Monday his condition was better, and the improvement was maintained on Tuesday

THE herbarium of the British Museum has acquired, by presentation from the widow, the very valuable collection of Muscineæ, made by the late Mr George Davies, of Brighton It comprises upwards of 20,000 specimens of mosses, hepaticæ, and lichens, partly gathered by Mr Davies in Great Britain and on the Continent, partly communicated to him from New Zealand, Samoa, India, the West Indies, and America

PROF HIERONYMUS has been appointed curator of the Royal Botanical Museum at Berlin

THE Exhibition of the Photographic Society of Great Britain was opened on Monday at the Gallery of the Royal Society of Painters in Watercolours It will remain open till November 10

WE regret to have to record the death of Mr George Croom Robertson He was fifty years of age, and only lately, in consequence of ill health, resigned the professorship of Mind and Logic at University College, London, to which he was appointed in 1866 Prof Robertson was well known as a brilliant teacher of the subjects to the study of which he devoted his life, and as the editor of *Mind* He was associated with Prof Bain in the editing of Grote's "Aristotle," and was the author of the volume on Hobbes in Blackwood's series of "Philosophical Classics" He also contributed to the latest edition of the "Encyclopædia Britannica"

DR GEORGE DIXON LONGSTAFF died at Wandsworth on Friday last in his ninety-fourth year When a young man he was assistant to Dr Hope, Professor of Chemistry at the University of Edinburgh, and he is believed to have been the first teacher of practical chemistry to medical students in this country. He was one of the founders and a vice-president of the Chemical Society of London

Students of folklore will be sorry to hear of the death of Reinhold Kohler, librarian at Weimar, where he was born in 1830 He died on August 15 Dr. Kohler was a man of great learning, well known as an authority on the subject in which he was chiefly interested.

THE American Academy of Arts and Sciences has published an excellent "Memorial" of Joseph Lovering, who was a Fellow of the Academy from 1839 to 1892, Corresponding Secretary from 1869 to 1873, Vice-President from 1873 to 1880, and President from 1880 to 1892. Mr. Lovering was born on December 25, 1813, and died on January 18, 1892. The "Memorial" consists chiefly of speeches delivered, and letters read, at a meeting held for the commemoration of his life and services, with a biographical sketch by Prof. J. P. Cooke, Secretary of the Council, and a list of Prof. Lovering's publications. At this meeting the chair was taken by Dr. A. P. Peabody, who said that there was a certain fitness in his leading the proceedings, as Mr. Lovering had been his pupil. Speaking of Prof. Lovering as a teacher of physical science, Prof. J. P. Cooke said: "He was one of the best lecturers I have ever known, and I have known the greatest masters of my time."

DURING the past week the weather has been of a decidedly cyclonic type; large disturbances have reached us with considerable frequency from the Atlantic, and have mostly passed to the northward of Scotland. The winds have been moderate to strong from the south-west, but have at times attained the force of a gale at places in the north and west, while on Tuesday they were boisterous in all parts of the United Kingdom. The rainfall has been somewhat heavy in the north and west, but light in the southern parts of the kingdom, where, during the first part of the period, the weather was generally fine, with occasional mist or fog in the mornings. The temperature has, on the whole, been mild, the day readings ranging from 60° to 65° over most parts, while in the extreme south they have exceeded 70° on several occasions. The *Weekly Weather Report* published on the 24th instant shows that some of the night minimum temperatures during that week were very low for the time of year, the shade thermometer falling to 25° in the east of Scotland, and to between 28° and 31° in most other parts.

AMONG the valuable discussions which appear in the *Repertorium für Meteorologie*, issued under the authority of the St. Petersburg Academy of Sciences, is one in vol. xiv., by B. von Nasackin, on the Storms of the Baltic, being in fact a continuation of similar works (by other authors) for the Black and White Seas. The data used in the discussion are taken chiefly from lightkeepers' journals and stations on the coast. The general results show that the yearly frequency of storms differs considerably in different years, and the number of storms at individual stations also varies considerably. In the western part of the Gulf of Finland and in the south of the Baltic storms are much more frequent than in the other parts. The mean wind direction lies between south and west, and the principal storms occur from the same direction, and also between west and north. The maximum number occurs almost everywhere in December, and the minimum in August.

Das Wetter for August contains an article by Dr. R. Assmann on the treatment of persons apparently killed by lightning. The different effects on persons struck would prove that the intensity of the flash is subject to considerable fluctuations, and recent photographs of lightning, in fact, show that in addition to the principal flash there are always weaker ones branching out in all directions, like the roots of a tree. It may therefore well be assumed that the intensity of the latter is considerably less than that of the principal current. He quotes a case near Berlin in the summer of 1891 where a number of soldiers were struck by lightning; among them an officer, and a bugler holding his horse, were both struck. The officer shortly afterwards recovered, while the bugler was to all appearances dead, but the officer at once adopted the method of artificial respiration as applied to the apparently drowned, by which means the bugler was gradually brought back to life. Dr. Assmann states that there can be little doubt that if this method were applied soon after the stroke, and continued for at least a quarter of an hour, many of those apparently killed might be restored to life.

A VALUABLE paper by Prof. E. W. Hilgard, on the relations of soil to climate, has been published by the U.S. Department of Agriculture. Soils being the residual product of the action of meteorological agencies upon rocks, it is obvious, as Prof. Hilgard says, that there must exist a more or less intimate relation between the soils of a region and the climatic conditions that prevail, or have prevailed, therein. Prof. Hilgard discusses, both from a theoretical and from a practical point of view, some of the more important phenomena dependent on this correlation, and their effects on the agricultural peculiarities of the chief climatic subdivisions.

HERR K. FLEGEL gives, in the *Allgemeine Zeitung* for September 12, an interesting account of archæological discoveries he has made this summer in the island of Kalymnos, near the coast of Asia Minor. At a height of about 220 metres, not far from Emporio, he found the remains of an ancient fortress which seems to belong to the same class of buildings as those of Mycenæ and Tiryns. The remains, which are comparatively well preserved, include Cyclopean walls and a tower. A gateway (1½ metre in breadth), the forecourt, a cistern, and a stone oil press survive. In the valley of Vathy, Herr Flegel came upon the remains of walls of an acropolis, which he describes as older than the fortress of Emporio.

IN the new instalment of the proceedings of the Liverpool Geological Society (Part 4, Vol. VI.), Mr. J. J. Fitzpatrick has some interesting notes on the Deep Dale Bone Cave near Buxton. In a paper read before the society in 1890, Mr. Fitzpatrick called attention to this cave, and described the various objects of interest which had been found in it up to that time. In his present paper he gives an account of the results of more recent researches carried on by Mr. W. Millet, of Buxton, by whom the cave was discovered. At the entrance is a refuse heap, three feet thick at the top, extending ten feet on either side of the entrance, and sixty feet down to the stream at the bottom of the dale. Among the objects found in this refuse heap are bones of the horse, stag, Celtic shorthorn (*Bos longifrons*), dog, pig, sheep, goat, wild boar, three flint flakes, a piece of bronze with Celtic pattern, fragments of pottery, including Samian ware, pseudo-Samian ware, Romano-British ware, coins of the Emperor Claudius, and female ornaments, including fibulæ, earrings, brooches, and rings. At the bottom of the heap were found two flint arrow heads. In the second chamber of the cave a hole, eight feet deep, has been dug. The upper bed, three feet thick, is composed of dark clay, with angular fragments of limestone. The second bed, which is from six to sixteen inches thick, consists of broken fragments of stalagmite, limestone, and gravel. In this a human jawbone has been found. The third bed, the thickness of which has not been ascertained, consists of a stiff yellow clay, containing large pebbles, two of which have been artificially pointed at one end. The human jawbone has twelve teeth, with the enamel and dentine in an admirable state of preservation. There were originally fourteen teeth, the two "wisdom teeth" not having been developed at the time of the death of the person to whom the jawbone belonged. The mark of the weapon which gave what was perhaps the death wound is distinctly visible. The weapon penetrated deeply into the bone in a slanting direction, with an upward inclination, and the blow must have been struck from behind. Another object found in the second chamber is a small bronze box, filled with

grey ashes, supposed to be the ashes of a cremated person The lid is moulded with the raised zigzag pattern common in Roman ornamentation, the hollow parts being let in with red and green enamel In the lower chambers, as stated in Mr Fitzpatrick's former paper, the following mammalian remains have been found —A skull of the brown bear (*Ursus arctos*), a skull of the Celtic shorthorn (*Bos longifrons*), teeth of the reindeer (*Cervus tarandus*), and of the red deer (*Cervus elaphus*), part of the skull of the wild boar (*Sus scrofa*), and some human bones

THE July number of the *Korean Repository* opens with an article by the Rev Dr Edkins on the Persians in the Far East He shows from native sources that at a very early period the influence of Persian ideas penetrated into China. The wide acceptance of these ideas was due in part to the doctrine of a future life, but Dr Edkins attributes even more importance to the worship of the god of fire as the special ruler of the hearth and the god to be worshipped by newly married people This, he says, is so adapted to the natives of Eastern countries with their strong family instincts, that it has easily kept its place and still has a firm hold on the popular mind In another article a writer who signs himself "Viator" indulges in much enthusiastic admiration of Korea and the Koreans He is especially emphatic in his praises of the scenery around Seoul, with its "grand amphitheatre of granite hills" "The city wall," he says, "climbing over the most precipitous ridges, the sentinel peaks of Nam San, with its chevelure of fine trees, and the bold castellated rocks of Poukan, which on the south and north respectively keep guard over the capital, with many other points both within and without the walls commanding varied and extensive views, would alone in any tourist frequented land make Seoul a show place of the guide-books" The ordinary Korean he describes as "a docile and happy creature"

WE learn from *La Nature* that MM Olivet, of Geneva, have brought out a new system of electric heating applied to conservatories, which may prove very useful where a motor force is at one's disposal A dynamo, worked by some motor, sends the current into receivers of special metallic composition, which become rapidly heated, but without exceeding a certain temperature A heated air current is set up as with steam-heating The advantages of the system are Absence of all unwholesome gas or vapour which might injure the plants, simplicity of construction in the parts conveying the energy, perfect safety as regards heat, which can be regulated at will, convenience and rapidity in starting and extinction, and cleanliness

MR A C MACDONALD, of the Agricultural Department of Cape Colony, refers with much regret (in the official publication of the Department) to the senseless way in which the ant bear is being exterminated This animal, he says, is one of the few indigenous four footed friends of the Cape farmer "Its food is the ant, more especially the white ant, an insect which feeds on our crops and the succulent herbage of the veld, and which does much greater damage than is generally supposed Although the ant has numerous enemies (among which is reckoned the koran, a bird which I am happy to say is now being preserved on some farms solely for this purpose), yet none are so destructive to its welfare as the ant-bear It is only when on the surface of the ground that the ant runs any danger from its winged foes, but above or below ground it is always within reach of the ant-bear But it is not only as a destroyer of ants that the ant-bear is of value to the farmer A large percentage of the seeds of our herbage, after they have dropped off the plant on the hard ground, lose their germinating power from being exposed day after day to the scorching rays of the sun The ant-bear, as it goes scratching about for ants, covers a large number of seeds with loose earth, in which congenial bed they will retain their reproductive power for a long period, awaiting the moisture from the skies to shoot out and propagate their kind And yet this animal, harmless in other respects, is being slowly but surely exterminated For its skin, which is valued at about 15s, and also for its flesh, which resembles superior pork, it is sought after by the natives With the white race 'sport' is the inducement, this fun taking the form at times of forcing the poor brutes out of their holes by flooding with water, or drowning them and digging them out afterwards"

PROF G C CALDWELL, of Cornell University, has been making oleomargarin a subject of careful investigation, and presents the results of his researches in a valuable paper in the September number of the Journal of the Franklin Institute He thinks that if made of unsuitable materials oleomargarin may contain germs of disease, and that the process of manufacture ought to be carefully inspected by capable officials, but there is no positive proof, he says, that it is now, or ever has been, made of such materials, or that any disease has ever been communicated to man by its use He is also of opinion that, when properly made from fresh and clean materials, it differs but slightly in healthfulness from butter He records, however, a rather significant incident which has recently come to his knowledge At an asylum for blind children, in Louisville, Ky, where good butter had been supplied, good oleomargarin butter was substituted No notice was given of the change, and even if the appearance of the substitute would have betrayed it, the blind children could not have seen it There was no evidence that they were in any way conscious of the change, but it was observed that they gradually ate less and less of the new butter and finally they declined it altogether No bad effect on their health could be discerned They made no complaint in answer to the inquiry as to the reason for not eating the butter other than that they did not care for it It was as if it did not adapt itself to any need of the system "This," says Prof Caldwell, "certainly must be allowed to count against the complete fitness of oleomargarin as a substitute for butter"

A FIELD NATURALISTS' CLUB was formed last year in Trinidad, and seems likely to do much useful work It publishes a journal, and in the third number, which we have received, gives reports of its meetings from the beginning In the meeting on January 8 Mr Mole announced that he had found a *Peripatus Edwardsii* in the St Ann's Valley, and Mr Urich stated that he also had found a specimen of the same species at Azouca

THE report of the Government Central Museum, Madras, for 1891 92, has been published In an interesting appendix Mr. H Warth, the officiating superintendent, gives an account, among other subjects, of the tin district in Burma The tin bearing deposits are, he says, of two kinds First, there is the tin gravel which is found in all or most of the valleys, a mixture of rough white quartz pebbles with sand, garnet, black tourmaline, and grey cassiterite The thickness of the gravel varies from 1 to 6 feet, and the yield of cassiterite may be put down as at least ¼ per cent or 1 pound of cassiterite (tin dioxide) in 400 pounds of gravel There are washings going on at many places, but some valleys have been more or less exhausted The work suffers also under the disadvantage that the greater part of the country is quite uninhabited, that food has to be brought from a distance, and that there is always danger of sickness. Chinamen are the chief workers The second kind of tin-bearing deposit is the original eruptive rock, which is weathered so that it is possible to wash out the grains of whitish cassiterite which it contains Mr Warth visited the principal deposits of this kind near Malewun in July 1891 He took samples from several excavations and washed them The mean is a yield of only 0 04 per cent. of impure wash tin.

Thus one pound of impure tin dioxide requires 2500 pounds of weathered rock. The rock is traversed by a series of parallel veins of white quartz indicating the origin of all the white quartz pebbles in the tin-bearing gravels, these gravels being nothing but the accumulation, during probably thousands of years, of the washings from the elevated outcrops of tin-bearing eruptive rock. The original tin-bearing deposit of weathered rock has been washed during a good many years. It requires a very good supply of water and very large deposits, otherwise the labour would be far too great and such works could not compete with those in the gravels. Among the rock specimens of the district are also grey limestones from Mount Tampra, three days' canoe journey from Lenya. This mountain Mr. Warth found fringed with caves which most likely owe their origin to the action of the sea. As they are now 160 feet above the sea, it appears that the land has been raised that much in comparatively recent time. If so, then the time during which most of the tin gravels formed was also comparatively limited.

THE third part of the tenth annual report of the Board of Fishery for Scotland has just been issued. It deals with the scientific investigations carried on during 1891. First there is a general statement of the results achieved; then comes a series of general reports; and these are followed by papers recording biological investigations. Finally, Dr. T. Wemyss Fulton gives an account of contemporary scientific fishery investigations in this and other countries. The following are the papers dealing with biological investigations:—On the food of fishes, by W. R. Smith; observations on the reproduction, maturity, and sexual relations of the food fishes, by Dr. T. W. Fulton; additions to the fauna of the Firth of Forth, part iv., by Thomas Scott; contributions to the life histories and development of the food and other fishes, by Prof. McIntosh, F.R.S.; on two large tumours in a haddock and a cod, by Prof. Prince and Dr. J. L. Steven. We may note that the volume is enriched with many admirable plates.

MESSRS. R. FRIEDLÄNDER AND SON, Berlin, have just issued the sixth annual report (for 1890) of the ornithological stations of observation in the kingdom of Saxony. The report has been prepared by A. B. Meyer and F. Helm, who have evidently spared no pains to make their work thorough and accurate. In an appendix observations relating to other animals in Saxony, besides birds, are recorded. There is also a list of the birds which up to the present time have been observed in that country, with notes as to their geographical distribution elsewhere.

THE Clarendon Press has reprinted Mr. J. G. Baker's "Summary of New Ferns discovered or described since 1874."

A WORK on "The Great Barrier Reef of Australia, its Products and Potentialities," by Mr. W. Saville-Kent, is to be issued by Messrs. W. H. Allen and Co. The barrier reef of Australia, represented by a vast rampart of coral origin, extends for no less than twelve hundred miles from Torres Straits to Lady Elliot Island on the Queensland coast. Between its outer border and the adjacent mainland it encloses a tranquil ocean highway for vessels of the heaviest draught. To the naturalist, and especially to the marine biologist, the entire barrier is described as "a perfect Eldorado, its prolific waters teeming with animal organisms of myriad forms and hues, representative of every marine zoological group." The author's object will be to render an account, in clear and popular language, both from a commercial and from a biological standpoint, of the most attractive subjects connected with the barrier region. There will be sixteen plates in chromo lithograph, with grouped illustrations produced from original water-colour drawings by the author, and forty eight plates in photomezzotype from original negatives.

THE New Zealand Institute has published its Transactions and Proceedings during 1891 (vol. xxiv., seventh of new series). The volume is edited by Sir James Hector, and contains many papers of considerable interest and value. The papers presented in the Transactions are grouped under the headings of Zoology, Geology, Botany, and Miscellaneous. The Proceedings include those of the Wellington Philosophical Society, the Auckland Institute, the Philosophical Institute of Canterbury, the Otago Institute, the Westland Institute, the Hawkes Bay Philosophical Institute, and the Nelson Philosophical Society.

THE *Journal of Botany* for September gives an account of the results of M. J. Bornmuller's botanical exploring expedition in Persia. The flora of the district visited is a very abundant one, but not many new forms were gathered. The mountain sides of Kuh Jupar, at a height of between 2900 and 3000 metres, were covered with dense forests of an undescribed species of *Ephedra*.

THE number of the *Oesterreichische Botanische Zeitschrift* for September is almost entirely devoted to the discussion of the question of botanical nomenclature, and the opinions on the various disputed points, of the leading English and Continental botanists.

MESSRS. CROSBY LOCKWOOD AND SON announce the following works:—"The Microscope: its Construction and Management," by Dr. Henri von Heurck, Director of the Antwerp Botanical Gardens, translated from the French by Mr. Wynne E. Baxter, F.R.M.S.; "Electric Ship Lighting: a Practical Handbook for Electrical Engineers and others," by J. W. Urquhart; "Toothed Gearing: a Practical Handbook for Office and Workshop," by a Foreman Pattern Maker, author of "Pattern Making," &c.; "The Mechanics of Architecture: a Text-book for Students," by E. W. Tarn; "The Visible Universe: Chapters on the Origin and Construction of the Heavens," by J. E. Gore; "The Health Officers' Pocket Book: for Medical Officers of Health, Sanitary Inspectors, Members of Sanitary Authorities, &c.," by Edward F. Willoughby, M.D. (Lond.); "The Art and Science of Sail Making," by Samuel B. Sadler, practical sail maker; "The Complete Grazier and Farmers' and Cattle Breeders' Assistant: a Compendium of Husbandry, originally written by William Youatt, thirteenth edition, entirely re-written, considerably enlarged, and brought up to the present requirements of Agricultural Practice," by William Fream, LL.D.; "Farm Live Stock of Great Britain," by Robert Wallace, professor of Agriculture and Rural Economy in the University of Edinburgh, third edition, thoroughly revised and considerably enlarged; "Tramways: their Construction and Working," by D. Kinnear Clark, M.Inst.C.E., new edition, thoroughly revised, in one volume; "The Wood-worker's Handy Book: a Practical Manual embracing information on the Tools, Materials, and Processes employed in Wood-working," by Paul N. Hasluck; "The Metal-worker's Handy Book: a Practical Manual embracing information on the Tools, Materials, and Processes employed in Metal working," by Paul N. Hasluck; "Practical Lessons in Roof Carpentry," by Geo. Collings; "The Steam Engine: a Practical Manual for Draughtsmen, Designers, and Constructors, translated from the German of Herman Haeder, revised and adapted to English Practice," by H. H. P. Powles.

MESSRS. BELL AND SONS are about to publish the following books:—"The Student's Hand-book of Physical Geology," by A. J. Jukes-Brown, with numerous diagrams and illustrations, second edition, revised and much enlarged (Bohn's Scientific Library); "Sowerby's English Botany,' Supplement by N. E. Brown, of the Royal Herbarium, Kew (to be completed in eight

or nine parts), "Fungus Flora," a classified text-book of Mycology, by George Massee, author of "The Plant World," with numerous illustrations, 3 vols, vols i and ii, "The Framework of Chemistry," Part I, by W M Williams

UNIVERSITY COLLEGE, Liverpool, has issued its prospectus of day classes in arts and science, and of the evening lectures, for the session 1892-93

PART 48 of Cassell's *New Popular Educator*, with title-page and contents to vol viii, has been issued The next monthly part of the work will form the first part of a technical series of Cassell's *New Popular Educator*, published under the title of Cassell's *New Technical Educator*

MESSRS DULAU AND CO have published a catalogue of works on electricity, galvanism, and magnetism—works which they offer for sale

FOUR lectures on Cholera will be delivered by Dr E Symes Thompson in Gresham College on October 4, 5, 6, and 7, at six o'clock p m The lectures will be free to the public

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♂) from India, presented by Mrs Trafford Rawson, a Green Monkey (*Cercopithecus callitrichus* ♂) from West Africa, presented by Mr A de Turckheim two Tigers (*Felis tigris* ♂ ♀) from India, presented by the Maha Rana of Oodeypore, a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mr Hugo Marshall, a Three striped Paradoxure (*Paradoxurus trivirgatus*) from Java, presented by Mr Douce, a Jackdaw (*Corvus monedula*), British, presented by Lt Col R F Darvall, F Z S, a Common Fox (*Canis vulpes*), British, presented by Mr Lucius Fitzgerald, an Indian Cobra (*Naia tripudians*), an Indian Rat Snake (*Ptyas mucosa*) from India, presented by Mr Arthur H Cullingford, F Z S, a Common Boa (*Boa constrictor*) from St Lucia, W I, presented by H E Sir Walter F Hely Hutchinson, K C M G, a Common Chameleon (*Chamaeleon vulgaris*) from North Africa, presented by Miss Withers, two Tarantula Spiders (*Mygale*, sp inc) from Demerara, presented by Mr H Strong, a Black headed Lemur (*Lemur brunneus* ♀) from Madagascar, a Duyker Bok (*Cephalophus mergens* ♂) from South Africa, two Demoiselle Cranes (*Grus virgo*) from North Africa, four Emus (*Dromaeus novae hollandiae*) from Australia, deposited, an Indian Chevrotain (*Tragulus meminna*) from India, two Violet Tanagers (*Euphonia violacea*) from Brazil, a Shag (*Phalacrocorax graculus*) British, purchased, three Wild Swine (*Sus scrofa*) born in the Gardens

OUR ASTRONOMICAL COLUMN

THE VARIATION OF LATITUDE AT PULKOVA —*Astronomische Nachrichten*, No 3112, contains two communications on the variation of the latitude at Pulkova, the first by Mr B Wanach, who discusses some old observations, and the second by Mr S Kostinsky, who has continued the former's recent observations made before July, 1891. During the years 1890 and 1891, Mr Wanach obtained some very definite results with regard to this question by using the large Pulkova transit instrument in the Prime Vertical, and the object of the present discussion is to find out if any like result can be discovered The observations used are those of W Struve made between the years 1840-55, O Struve 1858 9, Oom 1861 63, and Nyren 1879 82 If we employ those made in the years 1840 42 it is at once noticed that to satisfy the conditions a variation in the height of the pole of ±0" 1 has to be assumed, while the maxima and minima occur at different months of the year, the latter on September, 1840, May, 1841, March, 1842, and the former on January, 1841, September, 1841, and October, 1842 The observations from 1843 63 present no direct fluctuations in the value of the mean pole height, but show that it remains constant or is proportional to the time during the whole period Taking the values of the mean pole height for the years 1879 82, as obtained from a similar curve, it is found that a single sinus curve is not sufficient for the comparison, secondly, that the mean pole height is not the same as it was in 1841 and 1891, but is about 0" 15 greater, thirdly, that the chief maximum on March, 1881 coincides with the chief minimum on September, 1880, that is, exactly coincides with the phases of the pole height It also happens that the series, which take more than two years, give only one distinct maximum and minimum (instead of two, as would be expected) Coming now to Mr S Kostinsky's work, whose observations were made by W Struve's method with the aid of a large transit instrument by Repsold, the variation of latitude is clearly shown With the aid of the curve, which accompanies the paper, the maximum of the latitude occurs on October 4, 1891 Owing to the observations not being quite complete, the epoch of minimum is uncertain, but the curve shows that it will take place somewhere before the end of the month of May 1892 Comparing this curve with that obtained by Mr Wanach in the year 1891, we have for the dates of the greatest and least values of the latitude—

Max in 1890, September 14	$\phi = 59\ 46\ 18\overset{''}{.}39$	
Min ,, 1891, April 15	17 79	
Max ,, 1891, October 4	18 44	
Min ,, 1892, May 20-31 (about)		

DOUBLE STAR OBSERVATIONS —The second part of Appendix I to the *Washington Observations for* 1888 contains the observations of double stars made at the United States Naval Observatory during the period 1880-1891, by Prof Asaph Hall These observations have been made with the intention of carrying on the work that was begun with the same instrument in 1875 The stars here observed are mostly known binaries Some are of special interest on account of their short periods, while again the motion of others will be found to be very slow This volume will be welcomed by all double star observers, for in such a work as this a strict comparison of observations is needful in such measurements as are here dealt with The form in which the observations are printed is the same as was the case in 1881 The star's name is first given, followed by its right ascension and declination, and its magnitude In the first column the date of observation in years and decimals of a year is given, while in parallel columns the sidereal time of observation to the first decimal of an hour, position angle, distance, and weight of observation are similarly inserted, in two other columns the magnifying power employed and occasional notes are added for reference The volume concludes with an index of all the stars observed The numbers of the stars are for the most part those of the Struves, but Prof Hall, in recording those faint stars in the Pleiades, has referred them to Bessel's list of fifty-three stars in this group Bessel's stars themselves he has numbered in the order they appeared in the *Astronomische Untersuchungen*, first volume, p 237

SOLAR OBSERVATIONS AT ROME —In the August number of the *Memorie della Società degli Spettroscopisti Italiani*, Prof Tacchini contributes, in tabulated form, the results of the solar observations made at the Royal Observatory during the second three months of this year Considering first the faculæ, they seemed most numerous on the southern hemisphere, there being an excess of 13 Latitudes 20° to 10° north, and 20° to 30° south, were the zones of greatest frequency, the number recorded being 49 and 50 respectively Taking the whole numbers for both hemispheres the table shows a distinct increase, the numbers for the three months being 71, 75, and 97 With reference to the spots, the two hemispheres seem to have been evenly distributed, the numbers seen amounting to 48 and 46 respectively The zones of greatest frequency were found to be ± 10° ± 20°, the number of spots recorded being 29 and 22; but in zone −20°−30° as many as 19 were noted, the number in the corresponding zone of the northern hemisphere amounting only to eight The record of eruptions for this period is not very high, six only being seen in the northern and three in the southern hemisphere, the zone of maximum frequency for the northern hemisphere is + 10° + 20°, the same as that for spots, the six observations occurring in this zone alone, for the southern hemisphere the three eruptions were observed in each of the 10° zones included between −10° and −40°.

GEOGRAPHICAL NOTES

As the result of recent explorations by Lieutenant Fromm in the southern part of German East Africa, it appears probable that the difficulties which beset navigation on the Rufiji and Rovuma rivers are not so serious as has hitherto been supposed The resources of the country traversed by these rivers are reported to consist mainly of india-rubber in the forests An examination of a coalfield reported by Arabs as existing on a tributary of the Rovuma showed that the valuable coal seams were practically confined to the Portuguese side of the frontier

IN a recent number of *Petermann's Mittheilungen*, Dr Karl Grissinger publishes an interesting investigation of the physical conditions of the Weissensee in Carinthia The paper is accompanied by a bathymetric chart, which shows that the lake belongs to the same class as the long, narrow, deep lakes of Scotland, and by a remarkable diagram of temperature changes The latter is constructed so as to show the diurnal change of temperature at all depths from hour to hour for four consecutive days, and is in a high degree interesting and instructive Diurnal change of temperature becomes imperceptible at a depth of 37 metres, and the hour of maximum temperature is retarded as the depth increases Thus the surface maximum occurs about noon, while that at a depth of 25 metres is not attained until 8 a m of the following day

A RECENT official estimate of the coast line of the United States, including islands, indentations, and estuaries, gave as the total 90,900 miles Of this the Atlantic Ocean accounted for 36,500 miles, the Gulf of Mexico for 19,100, the Pacific Ocean for 8900, and Alaska for 26,400 Considering only the general coast lines, neglecting estuaries, bays and islands, the Atlantic margin measured 2000 miles, the Gulf of Mexico and Pacific Ocean 1800 each, and Alaska 4800, a total of 10,400 miles

M J GAUTIER has elaborated a system of photographic surveying, which is attracting considerable attention in France in view of the approaching revision of the cadastral survey of that country By means of a specially mounted camera, a series of twelve views are taken from one point, so as to comprise the entire horizon A set of signals, the position of which is carefully arranged, enable the various plates to be afterwards fitted together The map is subsequently traced out on waxed linen by a sharp point, a faintly printed copy of the photograph serving as a basis

THE uncertainty of communication with the Upper Nile valley makes it difficult to determine the precise weight to give to reports of events happening there But it appears highly probable that an expedition from the Congo Free State has at last succeeded in establishing a station at Wadelai, or some other point within the British sphere of influence The natural outlet of the region is of course down the Nile, and it is scarcely in accordance with the principles of geography that a prosperous development can ensue with so difficult an outlet as that to the Congo The practical aspects of the case are in their present stage more political than physical, and in this stage they are likely to remain for some time

ON Tuesday the *Times* printed the following telegram, dated September 26, from its Calcutta correspondent -Mr Conway's mountaineering party, which left Askoley on July 31, reached the foot of the Baltoro Glacier after four days' march, and proceeded up the glacier for four days They then climbed a peak north of it 20,000 feet high, which they named Crystal Peak, and hoped to get a view of the great peak "K²," but it was hidden by a neighbouring peak They then went another day's march up the glacier and climbed a pass to the east of Crystal Peak 18,000 feet high From this they saw "K²," but discovered that the map was altogether wrong in the representation of the neighbourhood of that peak They also found the Baltoro Glacier considerably longer than the map makes it A high peak not marked on the map stands at the very head of the glacier This Mr Conway named the Golden Throne They determined to try the ascent, and went one march further up the glacier and then were stopped by a snowstorm, during which they sent the coolies down to collect firewood They reached the foot of the Golden Throne on August 18, and then worked up behind the peak, climbing over 2000 feet through a very broken icefall. It took four days to establish and victual a camp above the ice-fall, at a height of 18,000 feet They moved next day to a camp 19,000 feet, and the day following to one about 20,000 feet high Thence, on the 25th, they started for a real climb, and having reached a point over 23,000 feet high, they found they were on a mountain entirely cut off from the Golden Throne, which was still 2000 feet above them The peak they ascended—which they named the Pioneer Peak—commanded a magnificent view, especially in the Hunza direction, where they could see to the distance of at least 200 miles They suffered from the great altitude, but not severely, and they could have climbed at least a thousand feet higher, and perhaps more They slept that night in their camp 20,000 feet above sea level They were obliged to descend next day as their provisions were exhausted Bad weather commenced on the 27th, and continued, putting an end to climbing for the present season Mr Conway has gone to Leh, for the purpose of comparing his barometer with the standard there, and accurately reckoning the height of the Pioneer Peak He expects that the comparison will show that they attained a height at least a thousand feet above Schlagintweit's 22,230 feet in Nepaul, which is the highest climb hitherto authentically recorded He will then return to India

THE IRON AND STEEL INSTITUTE

THE autumn meeting of the Iron and Steel Institute was held last week in Liverpool, under the presidency of Sir Frederick Abel The meeting was fairly successful on the whole, although the weather marred some of the excursions, and the last day's sitting was simply wasted time The following is a list of the papers read —"On the Manufacture of Iron in its Relations with Agriculture," by Sir Lowthian Bell, "On an Apparatus for Autographically Recording the Temperature of Furnaces," by Prof W C Roberts Austen, "On the Alloys of Iron and Chromium,' by R A Hadfield (Sheffield), "On the Liverpool Overhead Railway," by J H Greathead, "On the Engineering Laboratories in Liverpool,' by Prof H S Hele Shaw, "On the Failures in the Necks of Chilled Rolls," by Charles A Winder (Sheffield), "On a New Process for the Elimination of Sulphur," by E Saniter (Wigan), "On the Elimination of Sulphur from Iron," by J F Stead (Middlesborough) A paper on the basic Siemens process, by Mr Kupelwieser, of Witkowitz, was also on the list, but was adjourned until the Spring Meeting of next year

Upon the members assembling in St George's Hall, on Tuesday, September 20, they were welcomed by the Mayor of Liverpool, and the reception formalities being disposed of, Sir Frederick Abel gave a short address, in the course of which he commented on the papers about to be read, and also stated that Mr E Windsor Richards, of Low Moor, had been elected by the Council to be President of the Institute, in succession to himself, during the coming two years during which the presidential term lasts

The first paper on the list was Sir Lowthian Bell's contribution, which he read from MS, the paper not having been prepared in time to be printed Those who are accustomed to attending meetings of this kind know how difficult it is to follow the reading of a paper even when they have the help of a printed copy, but when one has to depend upon one's hearing only, in a large room and amidst many disturbances, the task is hopeless So far as we could gather, the author treated his subject *ab ovo*, and much of the first part of the paper might be found in various elementary text books The main point of interest was a description of an apparatus which has been devised for arresting and securing certain products which are to be extracted from the fumes of blast furnaces using raw coal The chief of these by-products is sulphate of ammonia, and the author pointed out how necessary it was to the harmonic working of an economic system that this sulphate of ammonia should be collected and returned to the earth as a fertilizer Of course, there is no gainsaying this part of the argument, and, as it is perfectly possible to collect the fumes and products of combustion, the question resolves itself into one of profit and loss Sir Lowthian quoted figures which would, in these lean times, make the ironmaker's mouth water, and almost convert the iron itself into a by-product, but unfortunately, as it appeared afterwards during the discussion, the selling prices which the author had taken were by no means those of the present day Mr Snelus spoke of the remarkable fertilizing properties of sulphate of ammonia and

nitrate of soda. He had spread one half of a newly sown lawn with a mixture consisting of one part of sulphate of ammonia to three parts of nitrate of soda—four cwt. to the acre—and had grass an inch long, whilst the unspread part was quite bare.

The next paper taken was that of Prof. Roberts Austen, in which was described a modification of the Le Chatelier pyrometer, which has been introduced for the purpose of securing autographic records of temperature. The apparatus was exhibited at the council table, and has been constructed under the directions of the author for Mr. I. P. Martin, of Dowlais, in order that a continuous record might be kept of the temperature of the stoves in which the blast is heated for the iron smelting furnaces. It will, of course, be understood that the apparatus is suitable for recording temperatures under other conditions, and it can hardly fail to afford valuable assistance to those engaged in many branches of manufacturing industry, and in the scientific investigating of processes; in fact, in many branches of metallurgical inquiry, and also in the study of steam engine economy, there has been no want more widely felt in times past than that of a trustworthy means of ascertaining high temperatures. The author had previously described an apparatus he had before devised, and that shown was the result of a desire to simplify the design. The original apparatus consisted of a camera containing a reflecting galvanometer of the Deprez and D'Arsonval type of about 200 ohms resistance. A thermo junction is connected with this galvanometer, and the amplitude of the deflection of a spot of light from the mirror affords the basis in calculating the temperature to which the thermo junction has been raised. An autographic record of the temperature may then be readily obtained if the spot of light from the mirror falls into a sensitized photographic plate actuated by an astronomical clock, or by other suitable mechanism. Such an appliance as this, though well adapted for conducting investigations, is not sufficiently simple for industrial purposes, and the author determined that it was necessary to simplify the part which receives and records the spot of light; and also to arrange for attaching several thermo junctions, so that there would be one for each furnace, and each might be brought in connection with the recording apparatus in turn. In order to effect these changes the original moving plate was replaced by a clockwork revolved cylinder, to which was attached sensitized paper. In the apparatus shown provision was made for placing any one of six centres of heat, such as hot blast stoves or furnaces, in connection with the galvanometer, and for obtaining within the period of the revolution of the cylinder a record of the temperature of any one, or of all the six sources of heat. The records will, of course, be intermittent, the duration of the test in any particular case being subject to the will of the operator; or the shifting of the electrical contact from furnace to furnace could be carried on by clockwork. The apparatus would then be entirely independent of manual adjustment.

In the discussion which followed the reading of the paper the most important point was that raised by Dr. W. Anderson, the Director General of Ordnance Factories, who asked what was the durability of the thermo couple, and whether the intensity of the current would alter owing to changes in the metals after exposure to high temperature. It will be remembered that the metals used are platinum and rhodium. Mr. T. Parker also asked if the couple was protected. Sir Lowthian Bell, who has had considerable experience with the Le Chatelier pyrometer in practical use at the Clarence Iron Works, said that in regard to durability and constancy of record, the device was most successful. He had only had to renew three or four couples, and they certainly would give accurate readings for the space of several weeks. He had proved this by comparing new and old couples, and also by testing at known temperatures. The author subsequently stated that the couples were put naked in the blast, and did not require protection unless subject to the impact of a shower of metal, in which case they were placed in a porcelain sheath.

Mr. Greathead next read his paper on the Liverpool Overhead Railway. This is a new railway which follows the "Line of Docks," and extends for a distance of about six miles. It is composed, for the whole distance, with the exception of a length of a few hundred feet, of an iron viaduct of uniform height, and which is continuous from end to end; unless some of the swing bridges on its course be open. The railway itself has been previously described, but the rolling stock has not, we believe, before been dealt with. Electricity will supply the motive power, there being a generating station situated about the middle of the line, where there will be four engines working up to 100 horse power, each driving a separate Elwell Parker dynamo. The current will be carried along the line by a steel conductor placed on porcelain insulators. Hinged collectors of cast iron, sliding upon this conductor, will make the connection between the motors on the train and the generating dynamos. There will be no separate locomotives, the motors being on the cars, two cars forming a train to seat fifty six passengers, the total weight being about forty tons. The signals will be worked by the trains themselves through an automatic device. The total cost of the railway is to be £85,000 per mile.

The second day, Wednesday, September 21, was opened by the reading of Mr. Hadfield's paper. This is a production of the kind that brings despair to the heart of those who prepare brief notices of these meetings. It consists, with the appendices, of over eighty three pages, besides numerous sheets of tables, diagrams, &c. It begins with Vauquelin, and ends with a bibliography—*ab ovo usque ad mala*, as the author himself says; but the difficult part of the matter is that throughout the whole treatise there is not a part that could well be left out without disadvantage to the reader. Having said so much it will be evident that we can give but a very faint indication of the contents of Mr. Hadfield's paper. It is well known that he has made a special study of the alloys of iron and chromium, generally known as chrome steel, and his success as a practical steel maker has been most marked. He has now put the results of long research and experiment at the disposal of all steel makers, and we cannot do better than refer those interested in the subject to the original work, which will duly appear in the volume of the proceedings of the Institute. It is noteworthy that chromium appears not to be in itself a hardener of steel, but that it acts indirectly by influencing the action of carbon upon the iron. Some of the photographic reproductions of chromium steel projectiles attached to the paper are very interesting, as showing what punishment this metal will stand. The shells go through nine inches of compound armour and eight feet of oak backing without apparent damage, the points being as sharply defined as in the shell as it comes from the shops. At a range of eighty yards two six-inch shells went through the thickness of armour mentioned, the striking velocity being 1825 feet per second, and the energy 2250 foot tons. One projectile altered ·01" in diameter and the second ·013". One of these projectiles was fired through another 9" plate without apparent damage. A 13·5" projectile, also of Hadfield's make, was fired at a target consisting of two armour plates with 20" of oak between. The first plate consisted of 18" of compound armour backed by 6" of wrought iron. Next came the 20" of oak, and then a 10½ wrought iron, and finally a 2" wrought iron plate. This gave a total of 36½" of steel and iron, besides the oak. The penetration was complete, but the illustration shows the projectile to have been broken into three parts. The striking velocity was 1950 feet per second, and the energy on impact 34,280 foot tons. The weapon was a 63-ton B.L. gun.

In the discussion which followed this paper—which the author read in abstract, having previously distributed printed copies—Prof. Roberts Austen pointed out that the author's researches supported the views taken by himself and Osmond as to the dual form in which iron exists. This was shown by the diagrams showing the rate of cooling which accompanied the report. In these, when the cooling was from a high temperature, 1320° C., the curve was continuous throughout, but when the cooling was from about a thousand degrees, there was a point of recovery indicating recalescence. The diagrams formed part of a report by Mr. Osmond on Hadfield's chromium steel, which the author had incorporated in his paper. Prof. Roberts-Austen said he had arrived at the same results working independently. Another point worth recording is that remarked upon by Mr. Vickers, who dwelt upon the difficulty of deciding whether the effects noted in the steel were due to carbon or chromium, as it seemed impossible to separate the one from the other, the chromium invariably disappearing with the carbon. Mr. Vickers also started the old question of hardening by oil or water, a process which he advocates. Dr. Anderson put the matter in its true light by pointing out the danger from untrustworthiness due to the hardening process, defects being sometimes set up of which there was no outward indication. This, of course, refers to metal in large masses, such as gun hoops, &c. Mr. F. W. Webb, the Mechanical Engineer to the London and North-Western Railway, gave high praise to chromium steel, saying

he used it entirely for springs and also with advantage for tyres. He likewise found it an excellent material for tool steel.

Mr. Winder next read his paper on the failure of chilled rolls. The breakage of rolls is one of the most annoying of the many troubles with which the producer of manufactured iron has to contend. This is a matter which has hitherto received too little attention, it being generally considered to be in the nature of rolls to break, and nothing man could do would prevent it. It is as evident as like produces like, that if some rolls will last for considerable periods of time, others of exactly similar description, and working under the same conditions, would stand equally long. Sometimes four or five rolls—the author instances eleven in a fortnight—will give out one after another, until at last one will be found to accomplish the work. Mr. Winder, as a roll founder, endeavours to bring some sort of order into the process of manufacture. He points out that when a train of rolls is hard at work in the present day they will turn out as much as 1000 tons a week, and the passing of this great weight of red- and white-hot billets or blooms will be almost equal to putting the rolls into a furnace. The necks of the rolls are, however, kept cool by water, so that the lubricant may not be burnt off, and the sudden cooling thus caused produces a molecular change in the metal which, the author considers, accounts for much of the mischief. In order to overcome this difficulty it is recommended that there should not be too sudden a reduction of the diameter of the body of the roll where the neck is formed. That, in brief, appears to be the author's opinion, and doubtless his advice is good; in fact, it follows one of the cardinal laws observed by good iron founders in the casting of other articles besides rolls. A good practical discussion followed the reading of the paper. We think that foundry practice is a little behind in this country, and in this respect we might, with advantage, take a hint or two from American methods, perhaps more especially in regard to smaller castings than chilled rolls, which often fail unaccountably in the United States also. The advice to roll founders to cast with a bigger head should not be, but apparently is, necessary. Prof. Turner's remarks were to the point, and it would be of advantage if he would make his researches in this direction more fully public.

Prof. H. S. Hele Shaw was the author of the last paper read on the Wednesday of the meeting. The Walker Laboratories form part of University College, Liverpool, and are among the most recent and best arranged establishments of the kind. They have been erected under the guidance of the author of the paper, who occupied the chair of Engineering Science when the school was in a far less magnificent form. We have not space to follow the author in his description of the buildings, or the method of instruction. The latter appears to be framed in a manner calculated to turn out good engineers, a class which cannot be too large for the welfare of the country, although complaints are growing daily that they are already too numerous for their own advantage.

The last day of the meeting was Thursday, September 22, when two papers were read. The first was the contribution of Mr. Saniter, and in it he described the process by which he proposes to remove sulphur from iron by calcium chloride and lime. The experiments quoted go to prove that lime alone removes a considerable quantity of sulphur from iron if the contact is sufficiently prolonged; and, further, that a mixture of calcium chloride and lime completely eliminated the sulphur in the space of half an hour. Chloride of calcium is a by-product of the manufacture of ammonia, of soda (by the ammonia process), and of Weldon's bleaching process. The author states that the production amounts to many thousands of tons, of which only ten per cent. finds useful employment, the remainder running to waste. The subject is one of considerable importance, and no doubt the process will be freely criticized when it comes up again for discussion at the next spring meeting.

Mr. J. E. Stead's paper on the same subject—the elimination of sulphur from iron—was a much more imposing contribution, covering 40 pages of the proceedings. It dealt broadly with the whole question, and forms a most valuable contribution to the literature of the subject. At the conclusion of the reading of his paper Mr. Stead said that since it had been written he had had further light thrown on the matter by experiment and otherwise. He therefore proceeded to read from a MS. certain fresh matter, which appeared to occupy as much space as the paper itself. No doubt Mr. Stead will weld the original paper and the additions into one harmonious whole, which will then form a standard work of reference on a subject which has come to the fore so much within the last year or two. We congratulate Mr. Stead upon his courage in dealing with this matter in the way he has, and especially upon the practical disclaimer of infallibility which the appendix to his paper supplied.

There was no discussion of these papers, their consideration being adjourned until the spring meeting of next year. The matter should be well thrashed out, as speakers will have had an opportunity of consulting authorities, marshalling facts, or even making fresh experiments. It is to be hoped that in the future more discussions will be arranged on similar lines.

The proceedings closed with the usual votes of thanks to those in Liverpool to whom the Institute was so largely indebted for the success of the meeting.

There were several excursions during the week. The chief of these were to the Manchester Ship Canal, the Vyrnwy Water Works, the Lancashire and Yorkshire engineering shops at Horwich, the Liverpool Overhead Railway, and Laird's shipyard. A visit was also paid to the Walker engineering laboratories, where Prof. Hele Shaw had collected some very interesting models for the occasion. The most striking of these was an exceedingly intelligent chain-making machine which has recently come over to this country from the United States. The whole of the operations are automatic, reels of wire going in at one end of the apparatus, and coming out one continuous length of chain at the other, and this without human intervention of any kind. The machine may, in the ingenuity of its design, rank with Laycock's horsehair loom, which we described in connection with the visit of the Institution of Mechanical Engineers to Sheffield of two years ago. It is really surprising to see what complicated operations mechanism may be made to perform by means of cams, levers, and springs. Mr. Laycock's loom exhibited perhaps a higher intelligence than the chain-making machine, inasmuch that it would select suitable hairs from a bundle, and would refuse to continue the work unless the proper kind were supplied. The chain-making machine, on the other hand, has to deal with a more stubborn material and has to connect each link. We do not know the name of the inventor of this machine, but the chain is known as "Triumph Chain."

FUELS AND THEIR USE

At the annual meeting of the Society of Chemical Industry held in London on July 20, the chair was occupied by Dr. J. Emerson Reynolds, F.R.S. He chose, as the subject of his presidential address, "The modern developments in regard to fuels and their use"—a subject, as he explained, which had occupied much of his attention. The address was one of popular, as well as of scientific, interest.

After some preliminary remarks, Dr. Reynolds said:—

The fuel question is one which concerns those of us who live on the western side of St. George's Channel even more seriously than it does you, as our coal beds have been washed away in ages past, and of native fuel there is practically none save peat; hence industries which require large quantities of cheap coal cannot flourish in Ireland under existing conditions. It is, therefore, our interest to watch closely the development of improved and economical methods of using such fuel as we can obtain from other countries, and apply them in the utilization of our bulky but abundant peat. It is evident that no other fuels need be considered save coal, peat, and petroleum; hence, my remarks can take somewhat the form of a trilogy, minus the dramatic element, precedence being given to the solid fuels, and the first place necessarily to coal.

The Royal Commission on Coal Supply, which commenced its sittings in July, 1866, and reported in July, 1871, after inquiring into all probable sources of coal in Great Britain, arrived at the conclusion that not more than 146,480 million tons were available at depths not exceeding 4000 feet from the surface. Therefore, at our present rate of increase of population and of coal consumption, our supply would not last for 230 years. But Mr. Hall, one of Her Majesty's Inspectors of Mines, who has special experience of coal mining, forms a much lower estimate of the supply practically available with our present means, and considers 170 years as the more probable duration of our coal beds. This estimate is based on fuller information than that possessed by the Royal Commissioners; we are therefore justified in concluding that the inhabitants of Great Britain 170 years hence will have little, if any, home raised coal to burn if we continue to use it in our present wasteful fashion.

It was pointed out by the Royal Commissioners in 1871 that we cannot suppose 'the production of coal could continue in full operation until the last remnant was used, and then suddenly cease In reality a period of scarcity and dearness would first be reached This would diminish consumption and prolong duration, but only by checking the prosperity of the country' 'Much of the coal included in the returns could never be worked except under conditions of scarcity and high prices A time must even be anticipated when it will be more economical to import part of our coal than to raise the whole of it from our residual coal-beds' As the area of coal bearing strata in North America is fully seventy times greater than ours, it is easy to see where our future supplies must come from The rate of increase in the use of coal has been greater than the Commissioners anticipated in 1871, and Mr T Foster Brown, C E, President of Section F of the British Association at Cardiff last year, has placed on record his opinion that at the end of only fifty years from the present time the increased cost of coal will be severely felt Pessimism is never pleasant, nevertheless we cannot afford to ignore reasonable inferences from fairly ascertained facts

I apprehend that there are few ordinary consumers likely to be influenced in avoiding waste by the knowledge that we are within measurable distance of the end of our store of British coal, as that calamity may still be some generations off But the case is very different with large consumers, the inevitable, if gradual, increase in the cost of coal has effectually arrested the attention of those directly concerned in our great industries or anxious for the maintenance of that manufacturing supremacy to which this country chiefly owes its wealth and power Keen international competition in trade has quickened the effort to get the utmost work out of fuel, and therefore to diminish waste

No such considerations have, however, produced any effect on the domestic conscience A spasmodic increase in cost of coal stimulates the use of various economical devices which are almost wholly given up when prices fall back nearly to their former level A small residual effect is left, which, though slight, is on the right side But that economy in the domestic use of coal which could not be effected by a patriotic desire to avoid the too rapid exhaustion of our coal beds, or by a fear of permanently dear coal, is likely to be brought about by the growing nuisance of large towns, namely, fog, for whose increase our 'hearths and homes' are in a greater degree responsible than the much abused factory chimneys The primary consideration in seeking to cope with the fog demon no doubt is to avoid the production of solid particles during the combustion of any fuel we may use, hence that method which avoids the formation of smoke at any time, and is both more convenient and economical, must ultimately 'hold the field' As you well know, various suggestions have been made for the purpose of avoiding the production of smoke, and it has even been proposed that the use of non flaming coal should be made compulsory in all large towns, notwithstanding the difficulties known to attend the combustion of anthracite or similar substances in open grates But even if the fog demon could be satisfactorily exorcised by such means, the fact would remain that the combustion of any solid fuel in an open grate is a most wasteful proceeding On the other hand, closed grates or stoves have not been popular in these countries How, then, can we combine economy in the use of coal with smokeless combustion and domestic convenience? The answer is sufficiently obvious—we must more or less completely gasify the coal prior to its complete combustion

The late Sir William Siemens showed us long ago how to convert coal completely into gas by means of his great 'producer' furnaces, and demonstrated the applicability of the comparatively poor 'producer' gas to operations requiring very high temperatures as well as to the minor work of steam raising Siemens showed that when so used one ton of coal can perform as much work as 1 7 tons directly burned. In such comparisons the 'producer' gas was, of course, burned at a short distance from its source and under the regenerative system This mode of using coal seems to be the most economical of which we have practical experience, but the gas which is produced seldom contains less than 65 per cent of useless nitrogen, and therefore is not rich enough in combustible matter for general distribution

The Wilson method of gasifying coal and that employed by the Leeds forge, permit the production of a richer gas The Wilson process involves the formation of a certain proportion of 'producer' gas in raising the temperature of the coal up to the point at which it can decompose steam, and then affords a mixture of carbon monoxide and hydrogen, or so called 'water gas' The former can be used for steam raising or furnace work in the immediate vicinity of the producer, while the water gas can be transmitted through mains as readily as ordinary town gas, and loses nothing by carriage save its initial heat Thus one general method affords two qualities of fuel and gasifies the coal in an economical manner.

Whether by the Siemens method in its modern form or by the more or less complete conversion into rich water gas, a great saving in coal can now be secured in almost all large operations requiring the command of high temperatures, and the use of such gaseous fuel is so steadily extending that we may expect in the near future to reach the maximum practicable economy of coal in our greater industries and of smoke abatement as well

Between the complete conversion of coal into gas and the very partial process included in the production of ordinary illuminating gas is a wide gap which needs to be bridged over in the interests of the small manufacturer and the domestic consumer alike before we can secure that economy in the use of coal which we know to be necessary For it must be granted at once that our ordinary 16 candle illuminating gas is seldom an economical fuel at an average price of 3s per 1000 cubic feet, though it is capable of being so used as to effect distinct saving under special circumstances As an example of its economical use, even near the price stated, I may cite the case of the kitchen of St John's College, Cambridge, where gas and steam have been substituted for coal, and an annual saving effected amounting to about £80 But in establishments which cannot be systematically conducted coal gas at 3s is too expensive a fuel Several solutions of this important practical problem have been proposed, one group of suggestions involving the supply of two distinct gases, an illuminating and a fuel gas, and therefore requiring two sets of street mains, but the progress of electric lighting is so rapid that gas companies would not be justified in outlay of capital on a second set of mains Another proposal is to supply one gas of high calorific value but low illuminating power at a cheap rate, and this gas, when used for lighting, to be charged at the point of consumption with vapours of suitable hydrocarbides But the true solution involves a compromise much on the lines along which gas managers are at present apparently working

You are aware that the average produce of 16 candle gas per ton of coal is about 9500 cubic feet By the introduction of steam to a small extent the volume of gas can be materially increased, but at the expense of the illuminating power In order to compensate for this loss, rock or other oils are injected along with the steam, and the illuminating power is maintained An objection to this practice is that carbon monoxide is present in such gas, but it is also found in many samples of ordinary coal gas, and provided the gas has a strong and characteristic odour, so that its escape can be readily detected, no risk need attend its use The supply of the richer bituminous coals is steadily diminishing, hence the practice must grow of supplying a modified water gas instead of coal gas as we have hitherto known it Better far, in the interests of producer and consumer alike, that the inevitable change in the character of the gas manufacture should be carried out with the full knowledge and assent of the public after due Parliamentary inquiry, and in such a manner as to secure the maximum advantage without undue interference with the great monopolies enjoyed by the gas companies So many satisfactory methods are known by which the illuminating power of a gas can be increased at or near the burner, and gas as an illuminant is moreover being so certainly displaced by the electric light that the objections hitherto urged against the supply of gas of high calorific value but low illuminating power have almost ceased to have any practical force On the other hand, the supply of a cheap gas of the kind I refer to would prove a great boon to small manufacturers as well as to the domestic consumer, and competent gas engineers inform me that no real difficulties lie in the way

The rapid extension of electric lighting in our large towns brings us within measurable distance of some such sweeping change in the character of gas used, in its applications, and in its mode of employment, while the existing mains would serve for its conveyance, and comparatively trifling alterations in our domestic appliances would only be necessary

It is in this direction, then, that the best prospect of solving a considerable part of the smoke fog difficulty seems to lie, and

it is in the same direction that we are to look for true economy in the use of coal. The completion of the system of electric lighting in towns is therefore to be desired by the community, not only on account of its great and obvious advantages for illumination, but because it will render possible the provision and distribution of a cheap gas for heating purposes; and the shareholders in gas companies of such fortunate towns should specially rejoice, as herein lies a good prospect not merely of maintaining, but of considerably increasing, their dividends. Gas companies would not only become purveyors of heat energy for domestic use, but for manufacturing purposes as well, not excepting the production of the electric light.

Hence, our duty to posterity and our own immediate interests coincide in requiring the use of more economical methods of using coal, and that which gives promise of the greatest number of advantages involves the conversion of coal as far as possible into gaseous fuel.[1]

I turn now from coal to peat, which is, as you know, a much less mineralized solid fuel. It is obvious that the question of peat utilization is one of much importance in Ireland, as nearly one-seventh of the island is bog. About 1,250,000 acres are mountain bog, and 1,575,000 acres are occupied by flat bogs, which occur over the central limestone plain of the country and stretch away to the north-west. This store of peat is an asset which may become valuable when you shall have exhausted your coal beds some 170 years hence. We would naturally desire to realize a portion of our assets at a much earlier date, as nearly all the coal used in Ireland must be brought from the eastern side of St. George's Channel. In this fact I think you have some explanation of the depressed industrial condition of the country, as manufactures involving the use of much fuel can only flourish in Ireland if the margin of profit be considerable; where the margin is small and competition keen (as in the greater industries), they must go under in the struggle with manufacturers having cheaper fuel at command. I grant at once that this is no adequate explanation of the absence of many chemical manufactures which do not involve large consumption of fuel, but it is the inevitable result in the cases to which my remarks apply.

Peat alone, however well prepared, compares very unfavourably with coal in several particulars:—

It is a very bulky fuel, in its ordinary condition occupying rather more than five times the space of an equal weight of coal.

2. It contains from 15 to 25 per cent. of water and seldom less than 10 per cent. of ash.

3. At least 2½ tons of average peat are required to perform the same work as one ton of average Staffordshire coal in ordinary fireplaces or furnaces.

Hence the general use of ordinary peat is attended by the disadvantages of requiring much greater storage room than coal, of producing a light and troublesome ash, and requiring more than thirteen times the bulk of coal to produce the same thermal effect. The last-mentioned consideration practically precludes its use in ordinary furnaces where heat of high intensity is required.

Now the force of the first objection to the use of peat, that of bulk, can be materially diminished by mechanical compression. Many excellent examples of compressed peat have been produced at various times, the most coal-like product I have seen being that of Mr. Hodgson, of Derrylea, who compressed, thoroughly disintegrated, and dried peat in heated cylinders, and by partially carbonizing under pressure secured the cementation of the material. Moreover, the ash of such compressed peat was not so bulky as that of the ordinary fuel.

I need scarcely say that the intensity of the heat obtainable with compressed peat is greater than with the loose material, but the actual thermal effect is not much altered, save in so far as the material is drier and therefore less heat is lost in evaporating moisture.

Extended comparative trials of coal and of good dense peat in steam engines have shown that the work done by one ton of peat was not more than 45 per cent. that of one ton of coal; hence if coal were 18*s.* per ton, peat could not compete with it under the most favourable conditions unless delivered at not more than 8*s.* per ton. Now the peat used in these trials did not contain more than 12 per cent. of moisture, but as dug from the bog it seldom contains less than 35 per cent. of water, even when cut from a comparatively dry bog; it must then be stacked and air-dried. The present price of ordinary turf delivered at the bog is about 7*s.* per ton; when to this is added the cost of handling this bulky fuel, and carriage for fifty miles, the cost exceeds 45 per cent. of that of coal even at inland towns; hence there is no real economy in the use of peat of the common kind in ordinary furnaces and grates instead of imported coal.

But the public are led by promoters of peat manufacturing companies, and others who should know better, to suppose that by certain processes of disintegration and compression peat can be made to approach very closely in fuel value to an equal weight of coal. There is no doubt that a better-looking and denser product can be obtained by these means, and one which requires less storage room; but unless artificially dried as well, the actual heating effect of the fuel is not materially altered. I have no doubt that the cost of winning and treating the rough peat could be much reduced by the use of suitable labour-saving machinery; but all methods with which I am acquainted involving artificial drying as well as mechanical compression, have cost so much that the product could not compete with coal at the ordinary level of prices. As I have already said, the Irish peat forms a valuable asset, but one not capable of being realized on any considerable scale at present; at least when used as fuel in the ordinary way as a substitute for coal. But it is possible to so burn peat that it shall compare much more favourably with coal, and this solution of the problem is obtained by converting rough peat into gas.

You doubtless remember that in 1872 the cost of coal advanced even beyond the panic prices which prevailed for a week or two about the beginning of the present year. But the coal famine of 1872 lasted for a considerable time, and serious efforts were then made in Ireland for the utilization of peat. It soon became evident that the continuance of dear coal meant the suspension of several industries and their probable loss to the country; hence, leaving to others the attempts to convert peat into a suitable fuel for general domestic use, I took up the industrial side of the problem.

I saw that the best chance for economically applying peat for most manufacturing purposes lay in gasifying the material in a Siemens furnace, as two special and important advantages must obviously be gained thereby:—(1) The use of peat in the rough state without artificial drying; (2) The avoidance of the injurious effects of abundant ash by burning the peat gas at some distance from its source, and under such conditions that the comparative value of coal and peat should be nearly in the proportion of their percentages of carbon. I therefore moved the Royal Dublin Society to appoint a committee of engineers and other scientific men to have the value of peat tested in the way proposed. The outcome was that the directors of the Great Southern and Western Railway of Ireland, acting on the recommendation of the able locomotive engineer, Alexander Macdonnell, C.E., decided to erect a complete Siemens regenerative gas furnace for working up scrap iron in their engine factory at Inchicore. This furnace was supplied only with rough peat, often containing as much as 38–40 per cent. of water, but no difficulty was found in keeping the welding chamber at a bright white heat for months at a stretch. The average consumption of fuel was 5.09 tons of peat for each ton of iron forged from scrap to finished work. Before the Siemens furnace was built the ordinary air furnace fed with coal was employed, and the average consumption per ton of iron was 4.96 tons of coal. I need scarcely say that peat is practically useless in such a furnace. Therefore peat used in the gas furnace as compared with coal in the ordinary welding furnace not only proved in practice to answer extremely well, but performed 97 per cent. of the work done by an equal weight of coal. As the price of peat was about half that of coal at the time, Mr. Macdonnell estimated that a saving of £4 7*s.* 9*d.* per ton of finished forgings was effected. If therefore the coal beds were exhausted we have a good substitute in peat for operations in which a very high temperature is required, provided the fuel is used in the gas furnace or according to some similar plan.[1]

The above remarks refer to work done twenty years ago. Now, thanks to the valuable investigations of Mr. Ludwig Mond, F.R.S., detailed in his Presidential Address of 1889, the pro-

[1] Since the above was written I have seen a short abstract of Mr. Valon's address to the Institute of Gas Engineers, in which I am glad to find that he takes a somewhat similar view of the situation to that expressed above.

[1] Of course the comparison is more favourable to coal when the latter is used in the Siemens furnace, as it is found that a ton of iron required an average of three tons of coal, therefore the work done by peat was about 60 per cent. of that by coal under the same conditions.

duction of ammonia from peat along with gas according to his method will probably pay for gasifying the fuel and materially facilitate the utilization of peat.

Much to my surprise and regret this work remains the sole practical outcome of our efforts in the direction of peat utilization during the fuel famine of 1872, so far as Ireland is concerned. Manufacturers now know how they can economically use peat for high temperature operations, and Dr Bindon Stoney, F R S, has suggested that peat should be gasified at the bogs and carried to convenient centres of industrial activity. This could undoubtedly be done, especially if instead of 'producer' gas a fuel were manufactured approaching water-gas in composition, and such a gas of good calorific power can be manufactured from peat. Thus, as in the case of coal, peat could be made economically to provide light and heat energy as well for domestic use as for manufacturing purposes. Would that we could apply even a small portion of the energy stored up in peat to stimulate those who should be most active in utilizing in the best and most economical way the abundant material almost at their doors!

If, then, there are many and great advantages in converting our bulky solid fuels into gas and distributing them in that form for heating purposes or supplying power by means of gas engines, it is clear that such advantages must be confined for the most part to towns or special manufacturing centres unless the gases are condensed to the liquid form, and so rendered portable to considerable distances, but nature has already done a great part of this work for us in providing the wonderful material we call petroleum. I do not think 'wonderful' is too strong an adjective to apply to this material, whether we consider its nature, speculate as to its probable origin, or attempt to measure its value in the world's work, and in this, the concluding section of my address, I propose to sketch in broad outline the main points of public interest which relate to this, the most important of our liquid fuels.

The views of geologists as to the nature of the general process by which petroleum is formed are elaborately discussed in the eighth report of the United States Geological Survey, and the conclusions are there carefully summarized (page 506). In substance they are as follow:—That petroleum is derived from organic matter by a process of slow distillation at comparatively low temperatures; that the organic matter was not in all cases of vegetable origin, but was in some instances derived from animal substances in contact with limestone; and, finally, that the stock of petroleum in the rocks is practically complete. It follows, of course, that the supply is exhaustible, but geologists do not even guess at its duration.

In contrast with all this is Mendeléeff's view that petroleum is not a product from organic material, but is chiefly formed by the action of water at high temperatures on carbide of iron, which he supposes to exist in abundance within or below the earth's crust. The cracks and fissures caused by the upheaval of mountain chains permit water to reach the heated carbide at great depths, and carbides of hydrogen result in accordance with the general equation—

$$3\,Fe_mC_n + 4\,mH_2O = mFe_3O_4 + C_{3n}H_{8m}$$

The hydrocarbides then distil up and condense within the cooler sedimentary strata. The occurrence of petroleum in active volcanic areas, as in Sicily and Japan, is held to accord with this hypothesis, which latter is also consistent with the remarkable fact that rock oil is usually found in the vicinity of mountains. But my chief reason for referring to this attractive hypothesis is that it permits us to suppose the hydrocarbides are still being formed within the earth's shell, especially beneath the geologically modern mountain chains, and that the supply of petroleum is practically inexhaustible. Whether that view can be sustained we must leave further evidence to decide, and now return after this digression to the consideration of the material itself.

The porous strata saturated with petroleum often lie at considerable depths below the surface soil of the district, and the oil is in many cases prevented from rising by a bed or shell of almost impervious material. In boring for the oil this enclosing shell is penetrated and the result often is the ejection of a column of liquid rising as a fountain of several hundred feet into the air. This violent expulsion of petroleum is due in great part to the pressure of pent up gases, and the crude liquid always contains some of these gases in solution. In some instances gas only issues, and a so-called 'gas well' is obtained, from which are emitted enormous volumes of marsh-gas and its lower homologues, as well as hydrogen. Some of these American gas wells afford from 10 to 14 million cubic feet per day, delivered at a pressure of as much as 400 pounds to the inch. Such gas is a fuel of high value and, as you know, has been largely utilized for industrial and domestic purposes at such great industrial centres as Pittsburg.

One million cubic feet of the natural gas obtained from the Trenton limestone at Findlay, Ohio, are said to do the same amount of work in heating as about 60 tons of Pittsburg coal. Some of these gas wells have been exhausted, but others have continued in full productiveness for several years. Although this natural gas is compressed and transported in cylinders to considerable distances, it evidently must remain of almost exclusively local value; not so the liquid petroleum which issues along with it or in its immediate neighbourhood. This is the most portable of all fuels obtainable in nature, and therefore is the most convenient means by which light and heat can be transmitted to all parts of the world—hence it is of greater practical interest to us than the natural gas.

You are aware that the hydrocarbides of which the American petroleum consists chiefly belong to the saturated group C_nH_{2n+2}, whereas those of Russian petroleum are mainly benzenoid hydrocarbides of the general formula C_nH_{2n}, isomeric with the olefines, but really hydrogenized aromatic compounds of the naphthene series. Petroleum from both sources affords some of the lower homologues of marsh gas, hence in the process of refining crude petroleum by distillation the first products consist largely of butane, pentane, and hexane, which are separated and condensed by pressure, the product being used for refrigerating purposes, owing to its high volatility. Between 80° and 120° American petroleum affords a spirit of specific gravity about 0·75, and above 130° the illuminating oils are obtained, whose gravities vary about 0·8, while the residue which is not vaporized at 300° includes the heavier lubricating oils, which are also admirably suited for use as fuel, and are cheaper than those generally used for lighting purposes. During this process of refining by simple distillation there is always more or less decomposition in progress, hydrocarbides of high molecular weight being resolved into simpler ones at a comparatively high temperature; and when crude petroleum or its constituents are rapidly heated, this resolution can be carried so far as to convert a large proportion of the oil into permanent gas, valuable alike for illuminating and heating purposes. Thus petroleum is a fuel which can be permanently gasified with facility, and is no doubt wholly converted into gas just prior to combustion in our common lamps.

Several methods are employed for the conversion of oil into rich gas, and storing the latter for distribution through tubes in the ordinary way. In one class of such processes the oil alone is rapidly heated to a temperature of from 800° to 1000° in iron retorts, as in the methods of Pintsch and Keith, thoroughly described by Dr Armstrong in vol iii of our Journal. The yield of gas seldom exceeds 130 cubic feet per gallon, as liquid hydrocarbides of low boiling points are condensed chiefly during the compression of the gas into cylinders for use in railway carriages. The gas is rich in carbon compounds, including methane, ethylene, and crotonylene, and its illuminating power, even after compression, is seldom less than forty-five candles. I may add that Mr Ivison Macadam has given in vol vi of our Journal (p 199) a valuable series of observations on the gas-producing power of various oils treated by a process very similar in plan to that of Pintsch.

Another mode of converting petroleum into gas includes the use of steam, as in the process of Messrs Rogers, of Watford, who inject the oil into red hot retorts by means of steam, the latter appearing to facilitate the permanent change of the petroleum without the formation of much carbon monoxide. The gas so produced is said to amount to about 140 feet per gallon of heavy oil used, and has, according to Mr. Rowan (this Journal, vol vii), the following composition:—

	Per cent.
Hydrogen	31·61
Marsh-gas	46·17
Illuminants	16·29
Carbonic oxide	0·14
Nitrogen	5·06
Oxygen	0·73

This gas is stated to have an illuminating power of fully 56 candles, and to lose little either by standing or by carriage to considerable distances.

As such petroleum gas has about 3.5 times the illuminating power of 16 candle coal gas, it follows that, so far as illuminating purposes are concerned, the gas producible from one gallon of oil by this process is equal to some 525 cubic feet of coal gas of 16 candle value. I shall later on refer to the heating value of this petroleum gas but I have now justified the statement with which this section commenced, viz., that petroleum is virtually liquefied gas in a peculiarly portable condition. Hence in all states petroleum can be used as an illuminant as well as a fuel, whereas coal and peat can only be used as illuminants in so far as they can afford carburetted gas.

Let me now proceed to justify the further statement that petroleum is the most concentrated, and, on the whole, the most portable of all the natural fuels met with in considerable quantities.

Weight for weight the efficiency of liquid petroleum in steam-raising is much greater than that of coal. The estimates of relative value necessarily vary with different portions of the crude material used, and with the quality of coal employed in the comparative trials, hence some of the statements of results are often rather vague. Thus M. d'Allest found that one pound of refined petroleum evaporated 12.02 pounds of water, while only 6.5 pounds were evaporated per pound of a rather poor steam coal. The American results with crude petroleum and Pittsburg coal give respectively 15 and 7.2 pounds of water per pound of fuel. Prof. Unwin has recently compared petroleum with Welsh coal in steam-raising, the oil being injected by a steam jet through a highly heated coil and then burned perfectly with a clear flame. In his trials with a not particularly efficient boiler he found that 12.16 pounds of water were evaporated per pound of petroleum, and this result he considers about 25 per cent. better than that afforded by the steam coal. These results agree with those of M. d'Allest so far as the effect of petroleum is concerned, but the coals compared were different in value for steam-raising. Hence for an average coal the proportion is nearly three to two, in other words the practical heating effect of one ton of coal can be obtained by the combustion of only two-thirds of a ton of petroleum, while the comparison with the heavy oils would probably be still more in favour of liquid fuel. Petroleum has another advantage over coal in the matter of storage room, as one ton of the liquid occupies only four-fifths of the space of the same weight of coal, so that the bulk of the petroleum required to perform the same work in heating as one ton of average coal is little more than half that of the latter. It follows that a steamer constructed to carry 1000 tons of coal could, if provided with suitable tanks, carry 1200 tons of petroleum, equal in fuel value to about 1900 tons of coal. In addition, the liquidity of petroleum permits it to be pumped and conveyed long distances by gravitation in tubes so that its transport in bulk and in detail is easy. Therefore petroleum is not only a much more concentrated fuel than coal, but it is eminently portable as well and convertible with much greater facility into permanent gas. Against these advantages must, however, be set the inflammability of petroleum, and consequent greater risk of fire.

Now we have to consider the question of relative cost of petroleum used as fuel in liquid or gaseous form as compared with coal, the latter being our standard for reference as in the case of peat. We have already seen that about two-thirds of a ton of petroleum can do the same amount of work in heating as one ton of coal, therefore petroleum, when burned directly, cannot economically replace coal unless two-thirds of a ton of the liquid can be purchased for less than the cost of one ton of coal. We know the cost of ordinary lamp petroleum in these islands is at present far beyond that limiting value, even the heavy oils which are not good enough for lamps, and yet are too 'thin' for lubricants, only compare favourably with coal where the latter has to be carried long distances, and is therefore dear. However, all practical difficulties having been overcome in the use of these heavy oils for steam raising, a comparatively small advance in the general price of coal would at once render them economical for industrial use as fuel.

But when we compare petroleum gas with ordinary coal gas the comparison is much more favourable to the liquid fuel, unlike coal, petroleum is already more than half way on the road to conversion into gas. As you know, one ton of coal affords about 9500 cubic feet of 16 candle gas. On the other hand, one ton of oil of sp. gr. 0.85 can afford about 21,000 cubic feet of gas, having an average illuminating power of 60 candles, or the equivalent of about 70,000 cubic feet of 16 candle value, and this rich gas admits of preparation on the small scale suited to country places, while the retorts used in the production of the gas can be heated by petroleum. The petroleum gas of some 60 candle power is said to be producible at about 6s. per 1000 cubic feet. If we were to assume that the calorific value of the gas is directly proportional to its illuminating power the cost would correspond to about 1s. 7d. per 1000 cubic feet of 16 candle coal gas. But the facts do not justify the assumption, as the calorific value of methane is known to be greater than that of the heavier carbides to which the high illuminating power is due, hence the comparison is probably less favourable to petroleum gas by about 25 per cent., though further experimental evidence is wanting on this point. However, even after this deduction, petroleum gas is the cheaper fuel as well as illuminant.

The necessary links between the elements of the trilogy on coal, peat, and petroleum are now, I think, sufficiently evident. If we desire to use each fuel in such a way as to develop most economically and conveniently its store of heat energy, we must first partially or perfectly gasify it. The newest member of the triad—petroleum—is the one which lends itself most easily and completely to such treatment, in consequence of its physical condition and chemical characters. It is also the material that we must expect to facilitate the production of cheap gaseous fuels from coal and peat which shall at the same time possess sufficient illuminating power for most purposes. Chemical industries would probably benefit to a greater extent than others by the supply of cheap fuel of the kind in question, hence I have ventured to tax your patience by dwelling on this topic in your presence to-day.

SUGAR-CANE BORERS IN THE WEST INDIES.

MR. BLANDFORD'S report on sugar-cane borers, published in the *Kew Bulletin* for July and August last, deserves more than a passing notice.

The report contains a plate of the insects in question, which will render their identification easy.

The first is a caterpillar and moth, *Chilo saccharalis*, the second a weevil, *Sphenophorus sacchari*, but the principal attention in the report is paid to the shot borer, *Xyleborus perforans*, a beetle which has lately caused considerable loss to growers of sugar canes in Trinidad. These losses have been so large that on some estates thirty per cent. of the sugar crop has been destroyed, and in some fields fifty per cent., presumedly by the devastations of this beetle.

This beetle *X. perforans* is to be found over a very large area in the tropics, it is the same species that has done so much damage to wine and beer casks, it has been found in India, the Malay Archipelago, Madeira, Mauritius, North and Central America, Brazil, Guiana, Peru, and probably in Australia, so that no sugar-producing country can consider itself free from the fear of its ravages.

Mr. Blandford's report is interesting and valuable, not only for the amount of information it gives relative to this most destructive insect, but also for the way in which he points out what remains still to be investigated on the subject, so that it not only furnishes valuable information to the planter in the West Indies, but also tells him what course his further investigations should take, and it might well serve as a model to future observers in drawing up similar reports.

"The chief subject for investigation," to quote Mr. Blandford, "is the relation of the insect's attacks to the health and condition of the canes, whether it (the shot borer, *X. perforans*) is a true destroyer, or merely a follower and manifestation of antecedent and more serious injury." this question, Mr. Blandford says, "I do not attempt to solve, it can only be studied in all its bearings by observers on the spot," and he further gives a list of definite points which require inquiry and solution.

There is no doubt that the presence of *X. perforans* is usually accompanied by the sugar-boring caterpillar, *C. saccharalis*, and the weevil, *S. sacchari*, and also with fungoid growths, which may of themselves account for the acidification of the juices of the cane, which is apparent in canes attacked by the shot borer, but whether or not the shot borer attacks healthy canes is a question on which there is much diversity of opinion, and we hope that bringing the question before our readers will lead to

more observations and experiments to decide this important question, as "while there is no proof, there is a strong presumption that *X. perforans* cannot begin the attack." Still there is much difference of opinion, as the Trinidad Commission, which investigated the subject, "believes that the beetle is the primary cause of the disease, and that it is immaterial whether the cane is healthy or not," others believe that it is only canes which are "already physically weakened by other causes which are attacked by it."

The Transparent Cane and Caledonia Queen enjoy an entire immunity from the attack, "even when growing side by side with badly infested Bourbon canes, and varieties raised by seed show no signs of being attacked." It is therefore suggested that perhaps the Bourbon cane, enfeebled by long cultivation on the same lands and degenerated by careless ways of propagation, has become powerless to resist the attacks, and planters in their investigation must consider the possibility of attacks "being favoured by constitutional weakness which in no way implies want of care in cultivation, but perhaps the reverse."

The enemies of the shot borer are still to be found.

An important lesson taught by this report to the planter is the necessity of varying the description of canes grown and the great value of the new seed canes raised in Barbados.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, Sept. 19.—M. Duchartre in the chair.—On the white rainbow, by M. Mascart. This phenomenon, usually known under the name of Ulloa's circle, is explained not on the untenable assumption of water vesicles, but of very minute drops as constituting the mist upon which it is seen. The diminution of the diameter of the drops causes a displacement of the first maximum of the interference fringes which produce the supernumerary arcs. The relative intensities of the various colours retain equal values long enough to make the rainbow appear achromatic, with perhaps a slight red coloration along the outside. The radius of such a circle has been known as small as 33° 30'.—Observations of the new planet Wolf (1892, Sept. 13), and of the planet Borrelly-Wolf (Erigone?), made at the observatory of Paris (west equatorial), by M. Bigourdan.—On a recurring series of pentagons inscribed to the same general curve of the third order, by M. Paul Serret.—On the production of the spark of the Hertz oscillator in a liquid dielectric instead of air, by MM. Sarasin and De la Rive. The two balls of 3 or 4 cm. in diameter between which the Ruhmkorff discharge takes place in the Hertz oscillator, were plunged into an insulating fluid. This was, in the first place, olive oil, contained in a cylindrical vessel, 20 cm. in diameter, pierced laterally to admit the end branches of the oscillator. Sparks 1 cm. long were obtained, giving a characteristic sound, louder than that of a discharge through air. The effect on the resonator is notably increased by the arrangement, most brilliant sparks being produced. The interferences of the electric force by reflection from a plane metallic surface give the same results as in air. During the discharge, the oil is carbonized and loses its transparency, but without affecting the intensity. Similar experiments were made with essence of terebenthine and petroleum, but the oil proved the safest and most advantageous medium.—The action of bromine in presence of aluminium bromide on the cyclic chain carbon compounds, by M. W. Markovnikoff. It has been shown that a small quantity of bromide or chloride of aluminium added to the bromine produces a vivid reaction with the carbon compounds of the aromatic series, usually resulting in substitution products of a crystalline form. Further experiments show the generality of the reaction for all the hydrocarbons of the series C_nH_{2n} which were examined. It has been studied chiefly as regards the naphthene (hexacarbon) series, and may be expressed by the general equation—

$$C_6H_{12-n}B_n + Br_{12-n} = C_6B_6-n + 6HBr$$

The rule seems to be that the action of the bromine on the naphthenes at the ordinary temperature takes place principally on the hydrogen atoms of the cyclic chain, transforming them into benzene nuclei, in which all the hydrogen atoms are replaced by bromine, whilst the lateral chains remain intact. It is found that besides the bodies of the aromatic and naphthene series, the hydrocarbons of the paraffin series also react easily in presence of $AlBr_3$.—The rotatory power of fibroin, by M. Leo Vignon.—Experimental researches on the bulb centre of respiration, by MM. J. Gad and G. Marinesco.—Influence of continuous and discontinuous electric light upon the structure of trees, by M. Gaston Bonnier. Out of three lots of plants, one was submitted to a constant electric illumination, another to an illumination alternating with twelve hours' darkness, and a third was left to develop in ordinary daylight. The experiments were carried out in the electric pavilion of the Central Markets at Paris. The temperature was pretty constant (between 13° and 15°), the light was given by arc lamps in shades, and the trees—pines, beeches, oaks, and birches—were surrounded by glass, the air being gradually renewed. It was found that continuous electric light produced considerable modifications of structure in the leaves and shoots of the trees. The plants breathed, assimilated, and secreted in a continuous manner, but they appeared as if encumbered by this continuity, and showed a simpler structure. The shoots were very green, the leaves more open, less firm, and smaller. Differentiation was less decided in every respect. In the specimens exposed to intermittent illumination the results were very similar to those obtained under normal conditions.—On the discovery of the line of no declination, by M. W. de Fonvielle. From an inspection of geographical maps preceding or contemporaneous with the discovery of America it appears certain that Columbus was the first to discover the variation of the compass. Indeed, it was the rapidity with which the observed declination diminished which produced consternation among his seamen, whom he could only save from a panic by persuading them that the pole star had changed its place, while the needle remained a true guide. The stratagem succeeded, but Columbus suspected that the radius of curvature of the earth was different at the Sargasso sea, and that the line of no declination represented a natural frontier between the territories of Europe and Asia. This natural frontier was adopted by the Pope Alexander VI. in his division of the new world between the rival aspirants. Columbus himself found that the line did not coincide with a meridian during his third voyage, but the illusion guided even Magellan, and was only dispelled by Halley's magnetic chart in 1700.

NATURAL SELECTION AND ALTERNATIVE HYPOTHESES

Animal Coloration an Account of the Principal Facts and Theories relating to the Colours and Markings of Animals By F E Beddard, M A, F R S (Swan Sonnenschein & Co)

THE theory of natural selection has been pre eminent for over thirty years as the most generally accepted explanation of organic evolution It has, and has had throughout, many critics, but its position is strengthened by the fact that these critics invariably accept the principle as accounting for something, while most of them make it clear that they reject all other proposed substitutes, except those for which they are individually responsible Sometimes the attempt to formulate an alternative hypothesis, or to apply it to the facts of nature, breaks down as soon as it is undertaken A curious instance of this is to be found in Semper's "Animal Life," which begins with very large anticipations —all the "popular cant" of the Darwinian is to be "put out of court as useless", a selective explanation can never be a real one, but for the latter we are to consult the subsequent pages But as case after case is examined, the author is constrained to admit that his real explanation is not forthcoming, and that, although he never will think much of selection, it is the only cause he has to offer Semper would appear to have written his preface before he considered the materials from which he proposed to write his book

Mr Beddard's work does not open in this ambitious manner, but he is far bolder in offering alternatives to natural selection, and in applying them Further consideration would probably have brought him to Semper's admission, at least as regards many of his suggestions Indeed, the number of these suggestions, and the confidence with which they are brought forward, are clearly due to haste and want of sufficient reflection, which also leave their mark upon the scheme of the volume and the number of contradictory statements to be found in it Nor is this to be wondered at when the amount and variety of work which the author accomplishes is borne in mind But the result will be to confuse the beginner and the untrained student Principles which are supposed to be refuted in one part, are subsequently introduced with considerable enthusiasm as the heads of the main sections of the work, and are later on again treated with scant courtesy In fact some readers will rightly infer that the author is a profound sceptic as to the value of the scheme he nevertheless adopts. Others may perhaps be led to suppose, by the arrangement of the book, that the author is sceptical of his own scepticism. Even the very fairness of the author in giving the arguments in favour of views he rejects, will be, such is the system pursued, a cause of confusion to a reader These sources of difficulty are not only apparent in the general scheme, particular explanations are disputed in one part, and adopted a little further on without a word of explanation

The chief value of the book lies in the fact that it is straightforward, and speaks out on points of great difficulty and dispute Arguments of which echoes have been already heard, perhaps, in the report of some conversation which is supposed to have taken place, or which have been crudely stated in the publications of unknown writers, are here met with in a form in which they can be dealt with For thus stating the opinions which are vaguely supposed to be held, perhaps vaguely held, by others, every Darwinian owes a debt of gratitude to the author

The main aim and purpose of the book would appear to be a criticism of natural selection as applied to the explanation of the colours of animals, and the proposal of alternative explanations

Some of the difficulties which the author finds in the theory of natural selection appear to follow from his conception of the process itself Thus, on p 12, he speaks of polymorphic species appearing in two or more well marked forms, and of those extreme cases of variation known to entomologists as "varieties," and concludes, "In fact, if colouring were really constant for a given species, there would be no chance for natural selection", thus implying that natural selection depends upon such pronounced divergences, instead of upon those minute differences which distinguish the individuals of every species He then continues, "Supposing that a marked variety occurs in a wild species, there is, first of all, a considerable chance against its reaching maturity, secondly, there is a considerable chance against its finding a mate, thirdly, the hereditary influences on both sides are against the perpetuation of the variety These appear to be more potent causes of the comparative fixity of colours in wild animals than the unfitness of the varieties to live" It has already been pointed out that the "marked variety" is of little importance for natural selection as compared with the individual difference But if the objections urged were valid there would appear to be little chance of a "marked variety" existing in any numbers and persisting from generation to generation, side by side with the normal form and yet numbers do persist As to the first of the alleged objections, the chances are against *every* individual, but not equally so, if there be anything in natural selection So far from this objection being valid, it is but the expression of a fact upon which natural selection rests, the fact that many more individuals of every species are born into the world than can by any possibility survive Were this not so all selection would cease The second difficulty certainly does not apply to minute individual differences which occur in vast numbers To take the simplest case, let us suppose that the individuals of a species are divided, as regards any character, into two equal groups—the one above, the other below the mean It is clear that each individual would stand as good a chance of mating within the limits of its own group as within those of the other The third objection does not appear to me to hold in the case of "marked varieties" any more than with individual differences The total hereditary influence of the varying side, allowing even considerable force for atavism, is certainly in favour of the variation Furthermore, experience shows us that among the offspring will be some that vary even further than their parent Those

who accept the Darwinian principle do not expect heredity to achieve more than this—to offer the materials which can be accumulated by natural selection.

Interesting as is the study of such "marked variations" and the statistics of their occurrence in nature, the great principle of natural selection, whether applied to the evolution of animal colouring or to any other character, is not greatly affected thereby, but rather demands such exact numerical investigations as those published by Galton upon man, by Wallace upon various animals, by Weldon upon *Crangon*, and by Lloyd Morgan upon bats.

Another objection to the natural selection argument is given on p. 25, and it too turns on the author's conception of the mode in which this principle operates. Recapitulating Weismann's argument that longitudinal stripes have been replaced by oblique ones in certain larvæ, on account of the more perfect concealment afforded by the latter, he points out that some species "have, on the contrary, remained at a stage of coloration which is, *ex hypothesi*, disadvantageous." The longitudinal striping was never disadvantageous, but only relatively less advantageous, in certain species, and under certain conditions. The failure of a species to take this line of evolution may have been due to many causes, the development of other modes of defence, the nature of its peculiar environment, or may be solely due to the kind of selection exercised by its foes.

The author sees far-reaching conclusions against the principle of natural selection in the admission that pigment as a cause of colour was originally non-significant, and is so still in many cases (colours of certain lower forms, colours of blood, fat, &c.). He argues (pp. 68-70) that as colour did not arise by natural selection, it must be a normal product of the organization, and its disappearance in cave-dwelling forms cannot be due to the cessation of selection, but must follow as the direct effect of surroundings, although he does not even hint at the mode in which such effects are supposed to be wrought. But these conclusions are by no means warranted by the original admission. The first appearance of pigment in the skin of the ancestor of a group of species which are now coloured was certainly a normal product of the organization; but the fact that this variation subsequently spread over all the individuals of the ancestral species, and of those to which it gave rise, will be claimed by Darwinians as the result of selection. And so strong are the tendencies of variation in other directions that partially or completely albino races can be produced by man in a relatively short period of time, while such individuals are far from uncommon in nature in spite of selection. The facts support the opposite conclusion that the absence of colour from the skin would be the normal result of organization for the average individual, were it not for the strong and continuous action of selection. There are other instances of the disappearance of colour in addition to that which has occurred in caves, and in some of these the conclusion appears inevitable. The whiteness of birds' eggs laid in dark holes certainly cannot be traced to the direct action of surroundings, any more than the colour of eggs laid in open nests; and natural selection being prevented by man, the colour is disappearing from the eggs of the domestic fowl, just as it is lost in other species when prevented by darkness.

It is certainly true that colour "must be there before it can be acted upon, and modified in this or that direction according to the needs of the animal." But this objection, which has been familiar since the earliest days of natural selection, is less formidable than it appears to be. Colour must have been present in the skin of some individual ancestor certainly, but its *existence*, as well as its modification, in the normal individual of the species is to be explained by selection.

It is hardly necessary to point out that this argument does not apply to colours which still remain non-significant and are excluded from selection; but these are precisely the colours which are unaffected by the changes of environment alluded to above; the blood of cave-dwelling vertebrates remains red like that of others; the yolk of eggs laid in holes does not differ in appearance from that of those laid in open nests.

A similar argument as to seasonal change of colour in arctic animals may be answered in the same manner.

The author's difficulties appear to arise in part from his inadequate conceptions of the struggle for existence. Speaking of certain night feeding caterpillars, he says (p. 102): "It may be suggested that they prefer to feed early in the evening, when their colours, if conspicuous, would be readily seen. If this is so, it does not much matter, for the birds would—the bulk of them at any rate—have gone to roost." Or speaking of *Mimnonectes*, an Amphipod crustacean which bears a remarkable likeness to a *Medusa* well defended by stings, he objects to attribute any significance to so wonderful and detailed a superficial resemblance, because "a school of whales or a shoal of pelagic fish, rushing through the water and devouring all before them, could hardly be supposed to stop and analyze carefully the advantages or disadvantages of selecting or rejecting a given animal as food." On p. 115 he remarks: "If Mr. Poulton is right in assigning a protective value to the bright-coloured wings of butterflies, 'as a conspicuous mark easily seized by an enemy, and yet readily tearing without much injury to the insect,' it seems unnecessary to pay much attention to the supposed utility of protective colours, such as are shown by the *Kallima* or the Green Hairstreak."

The author scoffs at natural selection as an "easy" road to an explanation, as "the very simple hypothesis of a need for resemblance to the environment." It may at any rate be maintained that this method of meeting it is very far from profound.

It is only possible to give a very brief account of the causes which the author would propose to substitute for natural selection. The merits of each proposal lie in its application, and the consideration of this means a discussion of each particular case.

In support of the "effects of food upon colour," a number of examples are quoted, many of which are so inherently improbable and so imperfectly supported by details, that it is impossible to accept them as evidence. I am very far from disputing that changes of colour may be directly produced by certain foods, although the significance of such changes in the evolution of animal colouring is a very different matter. When the author proceeds to

apply this principle he falls into errors which a little consideration would have avoided Thus, on p 21, the following sentence occurs —"Seeing that pigment has been proved in so many cases to be alterable by changes in the food, it is not surprising to find that as a rule the colours of larvæ are totally different from those of the adult form," implying that the difference of diet accounts for the difference of colour,—a conviction stated even more strongly on the next page It is quite sufficient answer to this hasty conclusion to point out that the colours of the imago are just as dependent on the larval food as the larval colours themselves, and that they have made their appearance long before the imago has had the opportunity of feeding Again, in speaking of the "strong superficial likeness" of the Drone-fly (*Eristalis tenax*) to a bee, the author hints at likeness of food as a possible explanation (p 232) "It is an interesting fact, in connection with the resemblance between this fly and a hive bee, that it feeds upon pollen and honey This fact *may* have some significance in relation to the effects of food upon form and coloration" But the form and coloration of *Eristalis* depend upon the food absorbed by its "rat-tailed" larva, living in putrid mud, under conditions utterly unlike those of the larval bee

Under the consideration of light as a cause of colour an extremely bad piece of reasoning is adopted from Werneburg (p 62), who argues that light has an important influence on the formation of pigment during the pupal period By selecting favourable instances and describing them with an enthusiasm which borders on inaccuracy (*e g*, speaking of *U sambucaria* as "bright yellow") and by neglecting all others, he makes it appear that there is something to be said for this view

In the section on "Variable Protective Resemblance in Chrysalids," the results of recent work are given very inaccurately, the golden colour of pupæ is explained as due to "thin films of air or some gas," and it is even suggested that "intense light may cause some gas to be given off in greater abundance" But it was shown years ago that the appearance is due to some lowly refractile liquid, and, in fact, alcohol answers the purpose very well indeed Gases do not appear to have the power of entering the intervals between the cuticular lamellæ, perhaps because the latter come together and obliterate the chinks on the evaporation of the fluid Again, it is stated that "the pupa was also made to assume a light colour upon one half and a dark colour upon the other" As a matter of fact the invariable failure of the pupa to do this formed the basis of some of the principal conclusions reached It was also surely unnecessary to quote an ignorant assumption of Eimer's on the subject—an assumption which was not even original, and has been disposed of long ago

In favour of the effects of climate reliance is placed on Scudder's conclusion that melanism is only found in the butterflies south of New York, albinism only to the north (p 55) And yet in Europe melanism is especially prevalent among the northern moths, from which we may infer that the American observations, however they are to be explained, are not direct effects of climate

He suggests that the blackness of a lizard on one of the Canaries may be due to moisture, but these islands are about as dry as small oceanic islands can be All the lizards seen by the present writer in Teneriffe and Grand Canary, some three or four species, were dark in colour and harmonized with the tint of the dark dry volcanic rocks on which they were seen, and among which they almost invariably escaped when pursued

One suggestion is very remarkable After giving reasons why he does not consider that the resemblance of *Volucella* to humble-bees, &c, is to be explained as a case of aggressive mimicry, the author suggests (p 228), "If wasps and bees have the same unintelligible liking for keeping pets that another group of Hymenoptera—the ants—have, the whole series of facts may prove to have a very different meaning, but one which is not quite in accord with the theory of mimicry on the part of the *Volucella*" The keeping of pets by ants is so very far from being unintelligible in some of the most important cases (*Aphides*, Lycænid larvæ, &c) that we may fairly expect an explanation in other instances But even if the author's suggestion were valid it would still fail to account for the very point at issue—the great superficial resemblance of *Volucella* to Hymenoptera

On p 92 he is quite prepared entirely to dispose of all advantages in the struggle for existence in favour of fertility, this alone is enough to prevent extermination. Speaking of the wonderful disguise of Geometer larvæ (and if this be not the result of selection it must be admitted that the principle fails indeed) he says, "In the meantime the excessive fertility of the parent moths appears to be a sufficient guarantee against extinction, apart from any subsidiary advantage to be gained by colour protection" It is sufficient reply to this statement to point out that the fertility of these small-bodied moths is very far from excessive when judged from an insect standard, that if the larvæ are offered to any insect-eating animals they are when detected, devoured with the greatest avidity, but that if offered motionless on their natural food-plant they are often passed over, that insect eating animals, especially when rearing their young, are by no means fed to repletion, so as deliberately to refuse the food they evidently relish

It is very confusing after this candid avowal to read a few pages further on (p 97), "On the whole, it seems more profitable to a caterpillar to adopt protective resemblance to its surroundings as a means of escaping its foes, at any rate, this is what actually occurs 'The main purpose in life of a caterpillar,' says Mr Scudder, 'next to feeding, is *not to be seen*.'"

Many quite irresponsible suggestions, which it would have been wiser to have withheld unless accompanied by at least some evidence, are made or adopted from other writers Of this nature are the remarks of Leydig on the colours of *Helix nemoralis*, and the author's suggestion that the dark variety of the female Silver-washed Fritillary may be due to the moisture of wooded districts

Of some of the author's suggestions we may use his own words, and say, "This explanation has an air of reasonableness, which might lead to the inference that it had been amply tested by actual experiment" (p. 64) Others however, including some which have been quoted here, certainly appear to lack this "air of reasonableness."

The author is especially candid and straightforward in bringing forward the evidence in favour of an explanation he is about to attack. After thus fairly showing the strength of the opposed position, he proceeds to reject it for reasons which will strike the instructed and uninstructed reader alike as singularly inadequate. Examples of this method occur continually throughout the volume. As an example may be selected his treatment of the opinion that the light of phosphorescent organs enables certain deep sea animals to see. He admits the existence of eyes, the prevalence of phosphorescence, the intensity of the light emitted, the existence of "lens-like transparent bodies serving to concentrate the rays of light," the fitness of the light to illuminate the prevalent colours. In spite of all these facts the author believes that all deep-sea colours are unseen and meaningless for the following remarkable reason:—"The presence of well-developed eyes, or the total absence of these structures, are, as has been explained, intelligible on the theory of abyssal light; not so the existence of eyes in an intermediate condition. The inevitable conclusion, therefore, from these facts appears to be that the brilliant and varied coloration of deep sea animals is totally devoid of meaning; they cannot be of advantage for protective purposes, or as warning colours, for the simple and sufficient reason that they are not seen" (p. 37). The author carries this conclusion to its logical end, and, pointing to the resemblance of deep-sea forms to their shallow-water allies, and the existence of protective resemblances in both, he maintains that "if natural selection has been the cause in the one case, it ought to be in the other. The question therefore is pressing: need natural selection be responsible for the coloration of the shallow-water forms?" (p. 38). A somewhat large conclusion to base on the fact that the eyes of certain deep-sea animals are in process of degeneration! The author admits that the *absence* of eyes is no argument for his views; and yet, in every such instance, a gradual process of degeneration has been passed through. He gives us no reasons for rejecting the opinion that the cases upon which he bases such startling conclusions are merely tending in the same direction; indeed, elsewhere (p. 11) he insists on the probability that such biological changes are still progressing. It is indeed most probable that light is far from widespread or intense on the floor of the ocean, and that, therefore, eyes to be of use must be unusually efficient, while, unless absolutely necessary, they are likely to disappear. We meet, in fact, with a case somewhat parallel to that of beetles on oceanic islands in tempestuous zones, where selection operates in opposite directions—towards unusual powers of flight, when flight is a necessity, and towards the total loss of any such capacity when it is unnecessary. Thus, among deep-sea fish we find eyes of immense relative size, as well as those which are degenerate. And the phosphorescent organs of certain fish (*Ceratias*) appear to emit a light which is invisible to the degenerate eyes of the possessor, but serves to attract other and better endowed fish upon which the *Ceratias* feeds. The frequency of this degeneration among the deep-sea Crustacea, which impressed the writer so profoundly, may very probably be due to conditions of life which render vision less necessary for them than for many other groups, and this is especially probable since many shallow-water genera are sightless, as is abundantly shown in the book itself (p. 36).

On pages 115, 116, the author adopts Prof. Weldon's objection to the usually received interpretation of the whiteness of certain eggs, and the under-sides of fish, porpoises, &c., which are seen from below, on the ground that snow-flakes appear almost black when seen from beneath against the bright sky. The original suggestion is due to neither Mr. Wallace nor to the present writer, but to Erasmus Darwin, writing very nearly one hundred years ago. The objection entirely misunderstands the hypothesis, at any rate so far as the eggs are concerned. If an egg lay exactly over one of the interstices in the nest, it would, of course, shut out the sky altogether, and when viewed from some distance through the opening would appear dark like the nest itself. There would be no question of its appearing against a back-ground of sky. As a matter of fact, no such continuous back ground can be seen through the nest at all. Minute bright points are seen through the interstices of the nest, and those of the leaves and branches above and below it. The hypothesis in question suggests that part of the bright white side of an egg, viewed obliquely from below through an interstice, may be mistaken for one of these bright points. The hypothesis may be erroneous, but it is not to be set on one side by a criticism which fails to understand it. In the case of the fish, the question is complicated by the absorption of light by the layer of water.

The reader who finds that the above-quoted criticism is held to be destructive by the author, may be excused strong language when he meets with the following sentence only seven pages further on:—"Among pelagic fish it is common to find the upper surface dark-coloured and the lower surface white, so that the animal is inconspicuous when seen either from above or below."

The chapter on Warning Coloration is one of the most valuable parts of the book, for in it we meet with a solid contribution to the subject in the form of some interesting experiments conducted by the author upon the animals in the Zoological Gardens. Many of the results are of extreme interest, and are a further proof of the difficulty of the investigation, and the great care with which it must be conducted if the conclusions are to be depended upon. It has been already suggested that some of the results may be perhaps explained by the fact that the insect eating animals chosen for experiment are restricted to a very monotonous or very scarce insect diet. In some rather extensive experiments made by the present writer upon a marmoset, it appeared that the animal possesses a most keen appreciation of the meaning of warning characters, but the individual in question was accustomed to be fed on a very varied diet. The discussion of the details given in this chapter cannot now be attempted, but it may be safely affirmed that there is nothing which is fatal to the theory of warning colours, when we admit, as we are of course bound to do, that even unpalatable animals have their special enemies, and that the enemies of palatable animals are not indefinitely numerous.

Further criticism of the arguments is rendered impossible on the present occasion by the exigencies of space. Certain obvious misstatements call for correction, such as

the description of the jet black larva of the Peacock Butterfly as "dusky greenish" (p 21), the assertion that the present writer discovered uric acid in the excreta of Vanessid imagos (p 41), the implication that leaf-mining larvæ eat only the deeper tissues of the leaf instead of everything between the upper and lower cuticle (p 63), the description of "red eye-like markings upon the blue underwings" of the Eyed Hawk Moth (p 134), in which red and blue should of course be transposed

The book is well printed, misprints such as "Tortorix" for "Tortrix" (83), "freshly-moulded" for "freshly-moulted" (67), "distinction" for "distinctive" (185) being fortunately uncommon

The coloured plates are good, although it would have been a pleasure to see the wings of one of the resting *Volucella* in Plate IV folded one over the other in a very characteristic attitude The antennæ of the *Kallima* shown at rest in Plate II would have been concealed, and the same applies to the figures of the Buff tip and Lappet Moths The worst figure is that of the Bee Hawk Moth on p 245, in which an entirely wrong notion of the opaque border to the wings is conveyed The source of the figures is not mentioned

EDWARD B POULTON

SUNSHINE

Sunshine By Amy Johnson, L L A (London Macmillan and Co, and New York, 1892)

THIS book is likely to puzzle any one who may by chance pick it up and glance casually over the pages, more especially if he should happen to first open it towards the end and find two chapters headed "Tommy's Dream," concluding with a conversational account of how "the nurse puts baby into a bath, generally too hot or too cold, and scrubs away as if he were a wooden doll Poor baby's skin is red all over, and he screams with pain," &c On the other hand, in the early part of the book, several familiar figures, such as pictures of ice flowers, or diagrams of the action of simple lenses, of total reflection, of the rainbow, &c, show that "Sunshine" is, in spite of the nursery episode, in reality connected with physical science As a matter of fact the authoress has taken a number of easy experiments and every-day observations, and has amplified and explained them in a simple and often very charming manner, adopting for the purpose the conversational form as between herself, called teacher, and, judging by the number of Christian names of the children addressed, a host of youngsters

The conversational style is out of fashion just now, but no objection can be taken on that account What is of far more importance is the general effect produced upon the mind of the child The writer of this notice well remembers how the attempt was made to beguile him into being interested in conversations between a horridly precocious child Willie and his papa Willie always said the right thing, and always made the right mistakes, so that much instruction was to be gathered from the answers and corrections of his papa The writer, no doubt, did acquire some general information, perhaps he did not resent the attempted deception, but he is sure that he would like to have punched Willie's head, or to have made him suffer in some way that is pleasing to the boyish imagination In the present instance the risk of arousing open hostility on the part of children who may receive instruction from the pages of "Sunshine" is largely reduced by the fact that the conversation is very one-sided, the children are made to say very little in these talks—they are not quite lectures, but more lectures than conversations Whether "teacher" says too much, or in the attempt to appeal to the imagination rather than the reasoning faculties of her audience rambles too far afield, is a question of taste Many parts of the book demand the highest praise, though in some the authoress seems to have gone beyond reasonable bounds For instance after a most clear and excellent illustration of the method by which the distance of the moon from the earth is determined, in which the children are made to find by folding paper how far it is from the table to a ball hanging up in the room, the imagination of the reader is stimulated as follows —

"At the beginning of our 'talk' about the moon, I tried to impress upon you what old travellers you were Do you remember how far you have been each year? (585,000,000 miles) And you, Tom, are——?" "Seven" "What age are you, Percy?" "Eight" "And you, Minnie?" "Nearly eight" "You shall work that sum out for me on your slates We will neglect the travelling since last birthday Multiply 585,000,000 by 8, Percy Four thousand six hundred and eighty millions of miles, you say Have you felt any pain or sickness? Are you willing then to accompany me for a little 'out' to call on our next neighbour, the moon? It is only 240,000 miles, and would take us a little over three hours and a half at earth's usual rate of travelling Do you think your mothers would trust you with me if I guaranteed to bring you safely back again? Most of you say 'Yes' What is it that Ethel is saying to you, Lucy?" "She wants to know if we are really going, or if it's 'only pretending'" "That is a question which Ethel must decide for herself Those who are going with us must be ready in time, or they will be left behind Before we make a journey it is usual to consider, not merely the distance, but a few other matters also, such as—'What to take with us,' 'How long we shall be away,' 'Where we can get lodgings,' Whether we should take shawls, umbrellas, &c,' and so many other considerations, that I am afraid we can't go to day Make all inquiries at home, and let me know how many of you are prepared to go"

As has been stated, the imagination rather than the reason is being constantly appealed to, and for the purpose the most picturesque language is employed Perhaps the most striking example is to be found in a chapter headed, "The Mill with Stained Glass Windows" A beam of sunlight is made to pass through a condenser and into a slit Then slips of coloured glass, red, green, and violet, are placed edge to edge over the slit, and the red-green-violet line of light is looked at through a scratch in a piece of smoked glass The resulting diffraction phenomenon is the mill with stained glass windows The upper story with violet windows has a greater number closer together than the second story with the green windows, and there is the same difference between this

and lower story with the red windows. From this result by a simple step the coloured bands seen when white light is employed are readily explained. Of course, and wisely so, no attempt is made to explain why with monochromatic light the windows are seen at all. In the same manner most of the phenomena described or which can be observed by following the clear and simple directions are stated to be what they are, rather than proved or explained. The authoress, guided by her own experience as a schoolmistress, is probably right in continually pointing out fresh phenomena of interest, which may or may not be immediately forgotten, rather than in wearying the child with difficult arguments which could at best be imperfectly understood, and which would be sure in many cases to awaken a feeling of disgust. In short, Sunshine is a kindergarten and not a school.

Simple and homely language is employed with the greatest propriety, but occasionally it tends to be vague or even to produce a wrong impression. One or two actual mistakes may be referred to in order that they may be corrected in a future edition.

Thus, it is stated that as a rainbow entirely vanishes when the sun is as much as 42° above the horizon we can never see one at noon. "In the summer" should obviously be added. The reader is told to spin a top carrying a disk painted half yellow and half blue and he will see green. There is a confusion here between the colour obtained by adding two colours as by spinning, and that which is the result of mixing pigments. As is well known, green is not produced under these circumstances, but white or nearly white. The four chapters on soap bubbles, which contain much that is sure to please, are supplemented by some special instructions, which, however, are not quite correct. Fig. 167 is an illustration of an experiment purporting to measure the surface-tension of a soap bubble by the depression of the water level in a quill tube dipping into a glass of water. As the bubble is drawn much larger than the two hands, the pressure within it would not produce any depression of the water below the general level. It would not even visibly affect the capillary elevation. Then it is stated that the surface tension of pure water is 16.62 grains per square inch. It is, as a fact, a little over three grains per linear inch. The confusion becomes greater in the passage, "We know exactly how much energy it (the elastic film of water) has—16.62 grains per square inch. A tube of 1-inch bore will lift up 16.62 grains of water."

There is one serious fault in the book. Serious because an experiment is described as though it were being performed to an audience which is not only impracticable and impossible, but which would require in a soap-film a property different in kind to that which it possesses. A school-slate frame with one end removed is hung up so that the remaining end is uppermost. A knitting needle is cut of such a length that it will slide freely in the groove made to hold the slate. From the knitting-needle a pill-box is hung by threads. The object is to weigh a letter. A soap-film is spread over the frame as far as the knitting-needle.

"See how the film is stretching, the knitting-needle is bringing it down like a blind. Now we place a letter in the balance. I know that it weighs just half an ounce, so I can mark on the slate-frame with my blue pencil the place where the knitting-needle stops for half an ounce. I see I was not mistaken in what would take your fancy! I will hang it up here. You shall make one for yourselves, and spend what time you please with it. You will not then easily forget how elastic the film is."

Now the surface tension of a soap film is so small that if the knitting-needle and pill box weighed nothing the slate frame chosen must have been eight or nine feet across, and the knitting-needle the same length; or if the letter and the pill box weighed nothing the knitting needle, if of steel, must have been a great deal finer than any in ordinary use. But even if the experiment were being performed on a minor planet, instead of at Manchester, where with diminished gravitation the half-ounce knitting-needle and pill box would only just be sufficient to balance the tension of the soap film, the description would give the false impression that like a metal or other spring the tension of the soap film increases as the film is stretched, and so is able to rest steadily at some point which depends on the stretching weight. One obviously invented experiment described with all the circumstance and detail that this is, is sufficient to shake one's faith in the genuineness of other demonstrations.

C. V. B.

STRETTON ON THE LOCOMOTIVE.

The Locomotive Engine and its Development. By Clement E. Stretton, C.E. (London: Crosby Lockwood and Son, 1892.)

THE author of this work is well known to the railway world as one who has long taken a great interest in everything pertaining thereto. No one probably has a better knowledge of the history and development of the locomotive. It is with much pleasure we welcome the volume before us. The author very properly gives to Trevithick the name of "Father of the Locomotive," he having used high-pressure steam, the smooth rail, and the blast pipe, some years before either Hedley or Stephenson began to experiment. It is a pity so many men connected with the early progress of the locomotive should have been lost to fame; all did their share—the few only have been handed down to posterity. William James, for instance, certainly should not be forgotten, he having had a large share of the work in proving the locomotive to be a suitable machine for hauling trains, as against the system of fixed engines and rope haulage, and to him is largely due Stephenson's success on the Liverpool and Manchester Railway.

Richard Trevithick was born April 13, 1771, in the parish of Illogan in Cornwall. He was a mechanical genius in many ways. His first engine was made in the year 1803. This engine ran on four wheels, the boiler was arranged horizontally and had a wrought iron return fire-tube; the cylinder was 8¼ inches in diameter, and the piston had a stroke of 4 feet 6 inches. It was arranged horizontally, the crosshead driving a shaft in front of the boiler by means of a return connecting-rod. This

shaft carried a heavy flywheel, and was connected to the carrying wheels of the engine by means of spur gearing The exhaust steam was discharged into the chimney, ensuring an efficient supply of steam

In the year 1808 Trevithick laid down a circular railway in a field which now forms the southern half of Euston Square. The locomotive exhibited had a vertical cylinder, the crosshead being coupled direct to the hind pair of wheels This engine weighed about ten tons, and ran at an approximate speed of ten to twelve miles per hour From these data it will be at once seen that Trevithick was before either Hedley or Stephenson with the invention of the locomotive engine, since both Hedley's and Stephenson's experiments date from the year 1813

The volume under notice is full of historical data having reference to these early experiments The author has taken great pains in arranging the matter Further on in the book, chapter iii, another most interesting subject is dealt with "The Battle of the Gauges" will long be remembered by engineers The standard gauge of railways in this country is 4 feet 8½ inches, measured between the heads of the rails This peculiar dimension appears to have been originally due to the tramways in use at the collieries where the original experiments were carried out by Stephenson and others, and was adopted for the railways when first projected and locomotives used The great exception to this standard was the seven-feet gauge of the Great Western Railway This railway, when projected by Mr Brunel, was intended to eclipse the narrow-gauge of railways, both in speed and comfort when travelling This competition, however, is claimed by the author as having been the means of hastening the growth and perfecting the locomotive Looking at the question from the present day, the 4 feet 8½ inch, or standard gauge, is certainly too narrow, the power of the locomotive has gradually been increasing since Stephenson's day, and a point will soon be reached when radical changes must be made in locomotive design, in order to increase the power still more. On the other hand, the now obsolete seven-feet gauge of Brunel was too large The Indian engineers have adopted the gauge of 5 feet 6 inches for the standard of that country This dimension appears to be a "happy mean," and one with which locomotive engineers may revel in large journals and free steam and exhaust ports in locomotives fitted with inside cylinders

It is amusing to read that American engines commenced their competition with the English engine in the year 1840, when some were imported to work the trains up the Lickey incline of one in thirty-seven on the Birmingham and Gloucester Railway These engines were made by Messrs Norris and Co, of Philadelphia, weighing slightly under eleven tons The author tells us they thoroughly beat the English engine of that day doing this particular service.

Every locomotive engineer knows what the Stephenson link motion is—the apprentice in his first year generally prides himself on having mastered its details, yet, for all this, the author tells us to call this old friend by another name! It seems that this gear is really due to Mr William Howe, an employé of Messrs R. Stephenson and Co, and was adopted by them and first fitted to an engine for the North Midland Railway in the year 1842 It may here be noted that the question of valve gear generally is not sufficiently described or illustrated in this volume The index contains several references, but these are very superficial This becomes all the more apparent when the Joy valve gear is fully described and illustrated, besides a diagram showing results of working

The Joy valve gear is in the opinion of many an unsuitable gear for a locomotive It must be evident that any gear which derives its valve motions principally from the vertical movements of the connecting-rod cannot give a good distribution of steam, for the reason that the vertical movements of the connecting rod are affected by those of the driving axle The driving-axle is not always in the same position as regards the frames and cylinders owing to the undulations of the road, the oscillation of the engine, and the varying condition of the springs, a movement of half-an-inch above and below the normal position of the driving-axle is quite within the limits of actual practice This movement is sufficient to affect the true movement of the valve, indeed, it is enough to destroy the lead either on the front or back ports as the case may be Besides this objection, the Joy gear has nominally a uniform lead for all degrees of expansion, whereas it is usually considered necessary to increase the lead for higher grades of expansion and speed of engine Some locomotive engineers are willing to risk this defective steam distribution in order to take advantage of the undoubted improvements in design the adoption of this valve gear allows These mainly consist in the increase in length of the driving-axle bearings for engines with inside cylinders, there being no eccentrics to find room for between the crank webs The cylinders can be consequently placed closer together, and the steam chest arranged either above or below the cylinders, as the case may be, without the use of rocking shafts or intermediate gear

Chapter IV deals with modern locomotives for main line trains. Many well-known engines are illustrated and described, and we naturally find the Compound Locomotives of Messrs Worsdell and Webb included in the number The author evidently is not enamoured with the compound locomotive, saying that "facts" are in favour of the simple engine It is here to be noted that no locomotive superintendent in this country, excepting the patentees of the respective systems, has adopted the compound system. What this is due to is uncertain, because the two-cylinder type of compound locomotive known as the Worsdell system has certainly given good results in India and other countries, comparing favourably with the simple engine The "Gladstone" locomotive, designed by the late Mr. William Stroudley, is among those illustrated This raises the interesting question as to the wisdom of using large leading coupled wheels for express work, many engineers prefer a bogie in front, deeming it safer But when the London and South Western Railway practically copy Mr Stroudley's arrangement of wheels in their latest engines for mixed traffic, one is apt to be surprised at the change coming from the "bogie" head quarters, and to surmise that anything will do. There is, however, nothing new in the adoption

of large leading coupled wheels, many engines were running in India of this design before Mr Stroudley adopted it, and the whole question can be narrowed down to the comparative life of tyres under different types of engines, there can be no doubt that a four-wheeled bogie or a Bissel truck in front saves the tyres of the leading coupled wheels, a larger mileage being obtained from them before they require to be returned

Chapter V includes a description of the sand blast arrangement for sanding the rails to prevent the slipping of the driving wheels This apparatus, small as it is, has left its mark on the design of express locomotives The single engine has again come to the front for express work with marked success, the latest design of Midland and Caledonian engines being examples

This volume taken as a whole is most interesting, and should be of value to all connected with the railway system of this country as a book of reference

N J LOCKYER

OUR BOOK SHELF

Sketches of British Insects By Rev W Houghton, M A, F L S, M S L (London O Newmann and Co, 1892)

It is satisfactory to find that there is sufficient demand for elementary books on entomology to render necessary a new edition of Mr Houghton's "Sketches of British Insects," and for those who, as dwellers in the country, wish to gain some insight into the insect life around them few better books could be found The differences between the several orders of insects and the main distinctions of the families are plainly and intelligibly set forth, though in a few instances the definition of terms and sections is somewhat faulty, thus, "Arthropod" would be more fitly translated "with jointed feet" instead of "with feet at the joints," and the numerous exceptions are not enough insisted on, there being for instance many insects with aquatic respiration and crustacea with aerial In Lepidoptera the tongue is often completely absent, whilst in butterflies the forelegs are never wanting, as stated, though in certain families they are rudimentary in both sexes or in the male only, and again the two pairs of spurs on the hind tibiæ are present in the vast majority of moths and also in many skippers The insects selected for description are well chosen, either as being conspicuous and typical of their families or as illustrating by their peculiarities some principle of adaptation to surroundings, though in many cases the classification is not according to modern ideas, thus, the clearwings (*Sesia*, &c) have no affinities with the beehawks (*Hemaris*), which belong to the *Sphinges* and the snouts (*Hypena*) are *Noctues* not *Pyrals* The account in the Introduction of the structure and metamorphoses is especially simple and clear, and the small volume is on the whole an admirable sketch of British insect life, though the coloration of the plates might have been made much less crude without adding materially to the cost of production.

The Birds of Lancashire By F S Mitchell Second Edition. Revised and Annotated by Howard Saunders (London Gurney and Jackson, 1892.)

We are glad to welcome a new edition of this book, which we reviewed shortly after the publication of the first edition NATURE, vol xxxii p 241) The task of preparing a new edition (in the absence of Mr. Mitchell from England) was undertaken by Mr. Howard Saunders, and it is scarcely necessary to say that he has discharged his duty thoroughly He has no personal connection with Lancashire, but he has had much help from local authorities, especially from Mr R J Howard, of Blackburn, and with their aid he has brought the book, as far practicable, up to date Several species have been added to the list, and there is a new index

Borneo Its Geology and Mineral Resources By Theodor Posewitz Translated from the German by Frederick H Hatch (London Edward Stanford, 1892)

The original work, of which this is a translation, has been reviewed in NATURE (vol xl p 49), so that it is unnecessary now to do more than record the fact that an English rendering of the book has been published Dr Hatch has done his work most conscientiously, and the translation is likely to be much appreciated by students of geology and mineralogy, and by all who have any reason for being specially interested in the material resources of Borneo

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

"A New Course of Chemical Instruction"

I AM much interested in the article in NATURE for September 29, entitled "A New Course of Chemical Instruction," especially as the writer, in the criticism of the book in question, whilst thinking that the method there advocated has theoretically more to recommend it than any other, doubts whether practically the time required is not an insurmountable obstacle

For four years I have been able to teach beginners in Chemistry on a method very closely allied to the one here proposed, that is to say, one in which no experiment is performed without a definite object in view—the final object being the solution of a given problem and no idea being given to the pupil of what the result will be, and I am glad to be able to say that the time required is *not* such a serious drawback as might be supposed, whilst the intense interest aroused and the training in scientific methods of work amply compensate for the slower acquirement of chemical facts

I have not the advantage of being acquainted with Mr Castell-Evans' book, so that I am not quite sure how nearly my work would agree with his course, but the fundamental principle is undoubtedly the same, and is the one laid down by Dr Armstrong in the report of the British Association Committee on Chemical Teaching, where he advocates the teaching of Chemical method rather than Chemical facts

What generally appals the beginner in Chemistry is the multitude of facts to be remembered, it seems a mere question of memory, and in consequence so dull and uninteresting, that the explosion or "burst up" is the one point to be looked forward to in the lesson By this new method the pupils themselves are put into the position of discoverers, they know why they are at work, what it is they want to discover, and as one experiment after another adds a new link to the chain of evidence which is solving their problem, their interest grows so rapidly, that I have seen at a demonstration lesson a whole class rise to their feet with excitement when the final touch was being put to the problem which it had taken them three or four lessons to solve Facts learned with so much interest are not forgotten and form a solid basis which it is true is slowly laid, especially at first, but it is interesting to see how much more quickly and easily later facts are assimilated, each one fitting itself in with the knowledge already acquired, and even when it becomes a ques-

tion of reading the account of work which it is impossible for the student to repeat for himself, the methods adopted are quickly understood and easily remembered, because the general methods of analysis and synthesis have, in an easy form, not only been used, but discovered by the student himself

This method of course breaks down where an elabbrate ex amination syllabus is imposed upon the beginner from the outset, and even where this is not the case, every teacher must adapt the method to his own conditions, only and always keep ing the fundamental principle in view

For the beginner in Chemistry whether he is later to specialise in this subject or not, experience has convinced me that the teaching of facts must give way to the teaching of method if a sound basis is to be laid in chemical science, whilst the subject opens the whole question of the value of Chemistry teaching from the educational point of view GRACE HEATH

The Temperature of the Human Body

THERE is a problem partly physiological and partly physical which I shall be grateful if any reader of NATURE can throw light upon

1 *The physiological* —I am assured by medical opinion in which I have confidence that the temperature of the human body is invariable from pole to equator of the earth The question I want to ask, assuming this to be true, is this What is the action in the body which exactly and everywhere counter-balances the radiation and conduction of heat in the one case from the body and in the other to the body? I thought at first that perspiration might have something to do with it, but my medical authority assures me that at the equator a man who perspires freely has exactly the same temperature as one that perspires little, although the former will be in good and the latter in bad health

2 *The physical* —Treating the animal as a heat engine, one is apt to think of the source of heat as the animal heat engendered by the combustion going on in his frame, and the refrigerator as the surrounding air at lower temperature—in the experience of most of us The animal then does work at the expense of this heat during its transfer from source to refrigerator, as in an ordinary engine On the other hand, the animal in equatorial regions must, if the physiological statement above be a fact, be often the coldest of surrounding bodies Does he also do work at the expense of the heat of combustion in his body, and if so is this vital action an exception to the second law of thermodynamics? If not, does he do work at the expense of the heat which is conducted into his body from hotter surrounding bodies, which heat, when he is doing no external work, still does not raise the temperature of his body?

Comet II 1892 (Denning, March 18)

THIS comet is still a tolerably easy object in my 10 inch reflector and will doubtless continue to be visible during the greater part of the ensuing winter It is now approaching the earth, and its brightness is increasing slightly During the next two months it will traverse Orion

I observed the comet on September 30, when it was in the same field as the 6th mag star Piazzi VI 144 (Lalande, 12546) By differential observations with that star I found the place of the comet to be

	G M T	α	δ
	h m	h m s	° ′
1892, Sept 30	12 50	6 25 51	+14 11

The theoretical brightness, as given in Schorr's ephemeris, was 0·62, but to my eye the comet seemed quite as plain as in March last The nucleus was, perhaps, not so distinct, but the surrounding nebulosity appeared to be more extended than on previous occasions

The comet will be close to ζ Orionis (the southernmost star in the belt) about November 14, and passes very near β Orionis (Rigel) on November 30 W F DENNING

Bristol, October 2

Cirro-stratus

A RATHER perfect example of one variety of this cloud was seen here in the afternoon of September 27 A rapid fall of the barometer until 5 A M, accompanied by a high wind, had been followed by a steady rise, the wind moderating some hours later At 2 p m, with a westerly light air, the sheet of cirro-stratus which overspread the sky appeared in the form of a series of very perfect undulations, stretching nearly north and south These were about fourteen in number, crowded together towards the east The lower surface of the sheet was sharply defined, and could be followed with ease in its successive rise and fall The cloud filaments could be also traced, preserving their perpendicularity to the wave fronts and conforming to the undulations of the lower surface with a closeness which I had not before observed, although sheets of cirro stratus are common here The whole system was drifting slowly to the east

A New Habitat for Cladonema

WILL you kindly allow me through your columns to note a habitat for this genus not given in Allman or Hincks. Several weeks ago I received some sponge from Mr Sinel, of Jersey, and on examining it with a hand-lens detected four polypites of Cladonema, one, at least, of which is still alive

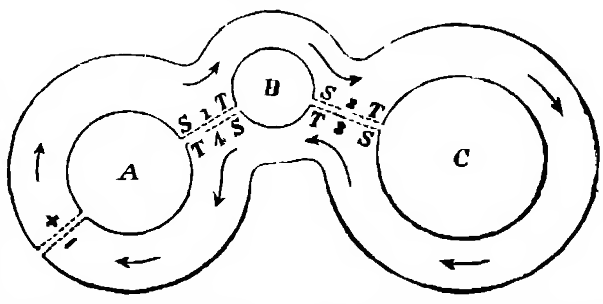
HENRY SCHERREN

5 Osborne Road, Stroud Green, N

TO DRAW A MERCATOR CHART ON ONE SHEET REPRESENTING THE WHOLE OF ANY COMPLEXLY CONTINUOUS CLOSED SURFACE

IF a solid is not pierced by any perforation, its surface is called simply continuous, however complicated its shape may be If a solid has one or more perforations, or tunnels,[1] its whole bounding surface is called "complexly continuous", duplexly when these is only one perforation, $(n+1)$-plexly when there are n perforations The whole surface of a group of n anchor-rings (or "toroids") cemented together in any relative positions is a convenient and easily understood type of an $(n+1)$-plexly continuous closed surface

Let the diagram represent a quadruplexly continuous closed surface made of very thin sheet metal, uniform as to thickness and homogeneous as to quality throughout To prepare for making a Mercator chart of it, cut it open between perforations C and B, B and A, A and outer space, in the manner indicated at $\frac{2}{3}$, $\frac{1}{4}$, and $\pm$ Apply infinitely conductive borders to the two lips separated by the cut at $\pm$, and apply the electrodes of a voltaic



battery to these borders By aid of movable electrodes of a voltmeter trace, on the metallic surface, and a very large number $(n-1)$, of equidifferent equipotential closed curves between the + and − borders Divide any one of these equipotentials[2] into parts each equal to the

[1] A "hole" may mean a deep hollow, *not* through with two open ends The word "tunnel" is inappropriate for the aperture of an anchor ring Neither "hole" nor "tunnel" being unexceptionally available, I am compelled to use the longer word "perforation"

[2] Two sentences of my previous article ("Generalisation of Mercator's Projection") in § 3, and in last paragraph but one, are manifestly wrong, and must be corrected to agree with the rule given for dividing into infinitesimal squares, in the present text

infinitesimal distance perpendicularly across it to the next equipotential on either side of it, and through the divisional points draw curves, cutting the equipotentials at right angles. These curves are the stream lines. They and the $(n+1)$ closed equipotentials (including the infinitely conductive borders) divide the whole surface into $n\ m$ infinitesimal squares, if m be the number of divisions which we found in the equipotential. The arrows on the diagram show the general direction of the electric current in different parts of the complex circuit, each arrow representing it for the thin metal shell on either far or near side of the ideal section by the paper.

Considering carefully the stream-lines in the neighbourhoods of the four open lips marked in order of the stream 1, 2, 3, 4, we see that for each of these lips there is one stream-line which strikes it perpendicularly on one side and leaves it perpendicularly on the other, and which I call the flux-shed-line (or, for brevity, the flux-shed) for the lip to which it belongs. The stream lines infinitely near to the flux-shed, on its two sides, pass infinitely close round the two sides of the lip, and come in infinitely near to the continuation of the flux-shed on its two sides. Let F_1, F_2, F_3, F_4 (not shown on the diagram) be the points on the + terminal lip from which the flux-sheds of the lips 1, 2, 3, 4 proceed, and let G_1, G_2, G_3, G_4, be the points at which they fall on the - lip. Let S_1, T_1, S_2, T_2, &c., denote the points on the four lips at which they are struck and left by their flux shed lines.

Let p_1, l_1, p_2, l_2, p_3, l_3, p_4, l_4, p_5 be the differences of potential from the + lip to S_1, from S_1, to T_1, T_1 to S_2, ... S_4 to T_4, and T_4 to the - lip. Measure these nine differences of potential. We are now ready to make the Mercator chart. We might indeed have done so without these elaborate considerations and measurements, simply by following the rule of my previous article, but the chart so obtained would have infinite contraction at eight points, the points corresponding to S_1, T_1, ... S_4, T_4. This fault is avoided, and a finite chart showing the whole surface on a finite scale in every part is obtained by the following process.

Take a long cylindric tube of thin sheet metal, of the same thickness and conductivity as that of our original surface, and on any circle H round it, mark four points, h_1, h_2, h_3, h_4, at consecutive distances along its circumference proportional respectively to the numbers of the m stream-lines which we find between F_1 and F_2, F_2 and F_3, F_3 and F_4, F_4 and F_1 on the + lip of our original surface. Through h_1, h_2, h_3, h_4 draw lines parallel to the axis of the cylinder.

Let now an electric current equal to the total current which we had from the + lip to the - lip through the original surface be maintained through our present cylinder by a voltaic battery with electrodes applied to places on the cylinder very far distant on the two sides of the circle H. Mark on the cylinder eight circles, K_1, K_2 ... K_8, at distances consecutively proportional to l_1, p_2, l_2, p_3, l_3, p_4, l_4, and absolutely such that l_1, p_1, &c., are equal to the differences of their potentials from one another in order.

Bore four small holes in the metal between the circles K_1 and K_2, K_3 and K_4, K_5 and K_6, K_7 and K_8 on the parallel straight lines through h_1, h_2, h_3, h_4, respectively. Enlarge these holes and alter their positions, so that the altered stream-lines through h_1, h_2, h_3, h_4 (these points supposed fixed and very distant) shall still be their flux-sheds. While always maintaining this condition, enlarge the holes and alter their positions until the extreme differences of potential in their lips become l_1, l_2, l_3, l_4, and the differences of potential between the lips in succession become p_2, p_3, p_4. In thus continuously changing the holes we might change their shapes arbitrarily, but to fix our ideas, we may suppose them to be always made circular. This makes the problem determinate, except the distance from the circle H of the hole nearest to it, which may be anything we pleased, provided it is very large in proportion to the diameter of the cylinder.

The determinate problem thus proposed is clearly possible, and the solution is clearly unique. It is of a highly transcendental character, viewed as a problem for mathemetical analysis, but an obvious method of "trial and error" gives its solution by electric measurement, with quite a moderate amount of labour if moderate accuracy suffices.

When the holes have been finally adjusted to fulfil our conditions, draw by aid of the voltmeter and movable electrodes, the equipotentials, for p_1 above the greatest potential of lip 1, and for p_5 below the least potential of lip 4, and between these equipotentials, which we shall call f and g, draw n-1 equidifferent equipotentials. Draw the stream-lines, making infinitesimal squares with these according to the rule given above in the present article. It will be found that the number of the stream-lines is m, the same as on our original surface, and the whole number of infinitesimal squares on the cylinder between f and g is $m\ n$. Cut the cylinder through at f and g, cut it open by any stream-line from f to g, and open it out flat. We thus have a Mercator chart bounded by four curves cutting one another at right angles, and divided into $m\ n$ infinitesimal squares, corresponding individually to the $m\ n$ squares into which we divided the original surface by our first electric process. In this chart there are four circular blanks corresponding to the lips 1, 2, 3, 4 of our diagram, and there is exact correspondence of their flux-sheds and neighbouring stream lines, and of the disturbances, which they produce in the equipotentials, with the analogous features at the lips of the original surface as cut for our process. The solution of this geometrical problem was a necessity for the dynamical problem with which I have been occupied, and this is my excuse for working it out, though it might be considered as devoid of interest in itself. KELVIN.

THE RECENT ERUPTION OF ETNA[1]

THE southern flank of Etna has been the site of three consecutive eruptions, remarkable for the diversity of the phenomena they presented.

On March 22, 1883, after several violent shocks of earthquake, the ground was rent open in a N.E. and S.W. direction, almost on the continuation of the big rift formed in the eruption of 1879, and near Monte Concilio a most interesting eruptive apparatus was formed. Very quickly, however, the eruption was arrested, but the eruptive energy had not had sufficient vent, as evidence of which were the frequent shocks which followed it and persisted, until on March 18, 1886, the ground was again split open as a prolongation of the rift of 1883, giving rise to an imposing eruption, during which an enormous quantity of lava was poured forth. This eruption from the very beginning manifested a great explosive force. The fragmentary materials were projected to an extraordinary height from several craterets formed along the rift, most of which, however, soon became quiet and were buried by the ejectamenta of the others, remaining alone the one twin crater now called Monte Gemmellaro. After this eruption the geodynamic phenomena and the volcanic activity at the central crater remained exceedingly feeble up to the last few days, so that this actual eruption did not present any grand display of premonitory phenomena.

On the evening of July 8, at about 10.30, the central crater of Etna began to send up a dense column of vapour, charged with dust, lapilli, and large rock fragments, which rose as an imposing mass with the

[1] This paper was written in Italian, and sent as a letter to Dr. H. J. Johnston Lavis, who has kindly translated it for NATURE, as requested by the author.

characteristic pine-shape of explosive eruptions, and illuminated by lightnings.

After half an hour this phenomenon ceased, and the smoke-plume was swept away by the higher currents of the atmosphere. I was able to ascertain in my excursion to the summit of Etna, in company with Mr. Rudler, curator of the Museum of Practical Geology of London, that the central crater was much modified by the short eruption. It presented two mouths, separated by a partition, whilst its upper edge was much broken down, so that it was enlarged. The ejected materials were composed of fragments of very much altered lavas that fell chiefly to the westward. During the night the ground was in a state of tremor, and at 2.45 a.m. of the 9th, a strong shock of earthquake was felt all over the Etnean region, producing slight damage to the walls of buildings.

Towards 1.20 p.m., without any further shock sensible in the inhabited regions, the southern flank of Etna was which is to the south of the new craters it divided in two principal branches and precipitated itself on the plain from which rises Monte Gemmellaro, forming three cascades of living fire. It here spread out, and the two branches, directing their course to the south, threatened Nicolosi, Belpasso, and Pedara. The more eastern ramification, when it reached the neighbourhood of Monte Albano, began to slow down and was already on the 12th advancing about two metres per hour, but increasing the breadth of its front and its thickness. On the other hand the western branch, which was invading the cultivated land, advanced in the steeper ground over fifty metres the hour, as I observed in my first visit on July 11. This stream was of a bright red colour, slightly covered by scoria. Near Monte Concilio it had filled up a valley, assuming a thickness of over 40 m. From Monte Ardicazzi we had presented to our view an immense expanse of fire from which rose crests and hills all in

FIG. 1.—Taken by Sig. Ledru on July 17. (No. 1, 2) are craters No. 1 and 2. (No. and 4) craters No. 3 and 4 in process of formation.—(m) Crateriform vent at the north base of crater No. 1.—(a) Monte Nero about one km. west of the craters.

rent open, and I could observe from Acireale a dense curtain of smoke rush up in great vortices, accompanied by continual rumblings. Towards evening one could see that the lava had advanced very rapidly in a southern direction. At the upper part it was observable that several jets, arranged in a linear manner, of fragmentary materials were being shot up to a great height, especially at three main points on the new and great rift. The explosive force of this eruption was much less than that of the eruption of 1886, in which the fragmentary ejecta were shot up to a height of 1200 metres, whilst in the present case the height rarely exceeded 500 metres. This fact depends on the great altitude and the great size of the new fissure, which afforded a free escape for the energy of the volcano, and gave forth a much greater quantity of lava. The lava in less than three days travelled more than four kilometres, and having surrounded Monte Nero, candescent, divided by deep depressions. It appeared like the sea in a tempest, the waves of which in their fury were suddenly petrified. From the crests were constantly being detached fresh incandescent masses which rolled down and choked the depressions, whilst new gushes raised the masses of scoria into new hills of fire. Amidst the phonolitic noise of the lava in movement, I noticed gigantic puffings produced by the escape of the vapour of H_2O, which, accumulating amidst the mass of the lava, formed gigantic bubbles which rose and burst, allowing the escape of the compressed gas.

The eruption was very active during the following days with short intervals of diminution or marked increase. Remarkable phenomena were the blasts which shook the doors and windows at Nicolosi, Acireale, and Catania, and, at localities nearer the point of eruption, even the walls.

On July 16 I started again, with my brother Giovanni, to approach the site of eruption. From Monte Caprioletto, which is about 1200 m distant, we could observe not only the three principal craters above mentioned, but also two others lower down, which so far had not grown to any important size.

Approaching still farther, we stopped at about 300 m off on the west, on a plain upon which grows the *Astragalus Siculus*, the bushes of which are now covered by large lapilli, and in part are burnt. The crater, which for brevity we will call No. 1, gave forth large and continual bursts of dust and scoria from its summit, and also from other points on its northern wall at the base of which issued a jet of light-grey vapour, which came from a little imbutiform crater separated from the main one by a partition of small size; from this were ejected a little dust and occasionally stones. The explosions of No. 1 were not accompanied by loud noises (*boati, bellowings*), but

Also in this last crater the explosions took place from several points of its funnel-shaped cavity, and we saw, at about mid-day of the 17th, much of its southern side destroyed by several bursts that took place from that point.

Both of these craters, already of considerable height, had an elliptical base, and specially No. 1, the maximum diameter of which is in the direction of the great rift, along which they are distributed.

The third crater, which we will call No. 3, adjoining the preceding one, presents a large depression to the south. It gave forth frequent bursts of incandescent lava fragments, with a constant noise resembling the constant discharge of much musketry, and accompanied by yellowish-white vapours. The emission of dust was rare, and only occurred when the eruptive bursts scored the north side of the crater. The fragments of incandescent lava, which in this crater were not accompanied by a trail of dust, often

Fig. 2.—By Sig. Ledru on August 19, at 100 m. to the north-east of the craters. (*S*) Crater of August 11. (*d*) Crater to the west which was in activity only on July 9. (1) Crater No. 1.

by strong and continual roarings like the sea in a tempest. Crater No. 2, more regular in form, gave forth frequent eruptions of dust, with many incandescent projectiles. In the moments of calm between one explosion and another, a slight white vapour escaped. The first burst of the explosion might be compared to a gigantic pointed jet preceded by black dust and sand, which rose with great rapidity in consequence of the great ascensional velocity, which was gradually impeded by the resistance of the air; then the column of black smoke charged with dust began to open out the immense vortices of compressed vapour which, always rising, assumed an imposing and characteristic aspect. The pieces of scoria were followed by a trail of dust both in their rise and fall, and when they struck the flanks of the mountain as they rolled down, they raised a cloud of dust and gave forth a characteristic sound. When they were numerous the mountain became all covered by a yellow dust.

were torn asunder in the air, being reduced to fragments.

The discharge of smoke from this crater occurred from the highest part, then there was the point at which occurred the numerous explosions of lava, then another jet of smoke, in its turn followed by another point lower down, from which occurred the explosions of the incandescent projectiles that gradually formed a crater, which we will distinguish as No. 4.

In general, while we were moving about to the westward of the craters on the morning of the 17th, the eruption was exhibiting comparatively little energy. Gradually, however, the explosions increased in violence, and the ejecta became more numerous. It is worthy of notice that the smoke, according to the place whence it issued was white, blue, light or dark grey, black, yellow, and even iridescent. Approaching nearer the craters, we attempted to encircle them on the north, when we found numerous

little fissures in the ground in a direction approximately parallel to that of the main rift These, often over a metre in breadth, are choked by the loose materials forming the surface, and in part obstructed by the loose materials forming their sides Higher up we found a wide cleft, which, starting from a higher point, was prolonged downwards towards the craters and was lost beneath the lava Upon this fissure were arranged a series of crateriform elevations, some of which were extinct, and others still presenting a little solfataric action On July 9, at the commencement of the eruption, lava and fragmentary ejecta also issued by this cleft, but it seems, the same day, to have become obstructed, and the tongue of lava which menaced the Casa del Bosco stopped, and the eruptive phenomena were diverted to the other more eastern fissure

It is absolutely impossible to accept the statement that this cleft represents the fire vents of the eruption of 1766, re-ejected, or are pieces of rock detached from the walls of the volcanic chimney Certainly from the last source are derived quartzites, which we collected amongst the ejected materials from this crater This quartzite is semi-vitreous, very similar to that which we collected from the craters of the eruptions of 1883 and 1886 These facts evidently showed that all these three eruptions have traversed similar strata and that all have arisen over the same principal cleft In fact the new eruptive apparatus formed at the base of the Montagnola about 1900 m above sea level, lies on the northern prolongation of the rift of 1886, in a plain gently inclined toward the south, and which towards the east presents a marked slope, so that the new craters are much higher on their eastern side In the great paroxysmal eruptions, and when a large rift opens at the surface of the earth, it is generally the rule that the eruptive mouth from which the lava flows without much explosive force is situated

FIG 3—Taken by Sig Modo on July 13, 1892, at 150 m to the north west of the craters Craters No 1 and 2 (a) Monte Nero (m) Little northern crater

and that the solfataric phenomena which the cleft now exhibits are only due to the near vicinity of the new volcanic outlet, for—putting aside the fact that in visits anterior to the present eruption I had never found any sign of such, and this is confirmed by people accustomed to the locality—it is easy also to be convinced from the nature of the materials composing these craterets These materials are so new as to leave no doubt as to their origin, and consist, those higher up, specially of blocks of old lava torn from the sides of the cleft, lower down they are principally scoria and other loose materials of recent formation

Approaching still nearer, we were able to distinguish clearly that amongst the ejected materials of No 1, besides the number of fragments of molten lava, there are often blocks of a dark grey colour that were already consolidated before their final ejection, which are either projectiles that have fallen back in the crater and have been at its lowest extremity The higher one goes along the fissure the less is the amount of lava that issues, but the greater is the explosive action, which higher still itself in turn diminishes In the present eruption we have good examples of this In fact, the small northern crater gave forth only dust, and very few fragments of new lava, and with little energy No 1 crater emitted much dust and also much lava, No 2 more lava than dust, and Nos 3 and 4 exclusively lava The materials of the little northern crater (Fig 3) are for the most part fragments of ancient lava, which lose their predominance in crater No 1, and gradually disappear as one descends lower and lower At the same time, as the old lava has a light bluish-grey colour and the fragments of the newer lava are much darker, the different craters exhibit different colours. This difference also depends in part upon the degree of fineness of the materials that compose the craters In fact the northernmost crater at the beginning

of the rift had not sufficient power to eject large materials, but lifted them up and kept them in continual movement, reducing them to fine dust, which was easily carried out by the vapour. No 3, on the contrary, continually ejected large lumps of lava, often shooting them a considerable distance, whilst Nos 1 and 2 exhibited intermediate stages, quite confirming what has been said above.

Whilst we were there the eruption increased little by little. The ground commenced to vibrate, and at 3.47 p.m. we

Fig 4.—Taken by Sig Mordà on July 18, 1892, at 300 m to the north west of the craters. (1 and 2) craters No 1 and 2 (a) Monte Nero (d) Craters to the west which were in activity only on July 9.

felt a strong earthquake shock, followed by other frequent oscillations of the ground of less intensity but often very perceptible. In this new period of great activity general to all the craters the phenomena exhibited by No 2 were worthy of remark. It no longer ejected dust, but pieces of hot lava with stronger explosions, which were more frequent but of shorter duration. Between one explosion and another there was slow evolution of white vapour, similar to that which rises from the fire-mouths and

Fig 5.—Taken by Prof Riccò on July 20, west of the craters. (1, 2, 3) craters No 1, 2, and 3

surface of the running lava. This floated above the crater, slightly disturbed by the wind, and when an explosion occurred it assumed a curious vibratory movement, rising a little, and then rapidly descending; then immediately was seen the first jet of solid materials, which, in its vertiginous upward course by vortex movement, sucked in the air over the crater edge, and the white vapours were drawn down, so looking as if they were being reabsorbed. This phenomenon, which attracted our attention when I was with you on Stromboli and the members of the Geologists' Association,[1] would show that within crater No 2 there is pasty lava, which is pushed up by the vapour in it; then the magma swells up, bursts, and the lava falls.[2]

In this parasitic crater of Etna, however, the phenomena were on a much larger scale, as also were the smoke vortex rings which we looked down upon when we were together at Stromboli. Likewise the explosions were far louder, reverberating as a low-pitched roar by the echo of

Fig. 6.—Taken by Prof Riccò on July 20, to the north west of the crater. No 1, 2, and 3 (a) Monte Nero.

the valleys, and they were audible in all the Etnean region, at Catania, Acireale, Giarre, and farther still for some dozens of kilometres from the craters. The air-shocks that accompanied these reports were very interesting. They represented a large undulation of the air, spreading with great velocity, reaching great distances, and contemporaneous with the audible vibrations.[3] While there we felt the blow on our bodies, and especially our chests and in the ears; at the Casa del Bosco we detected the shock against the walls, which trembled, and

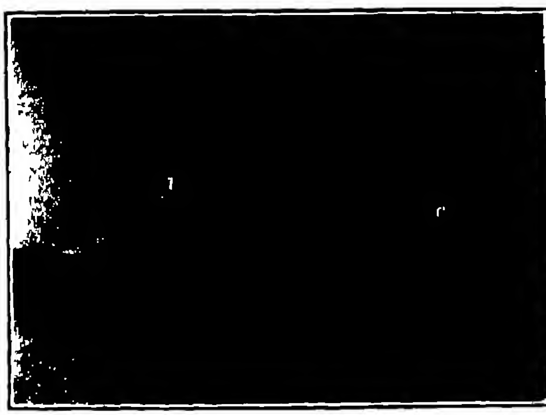


Fig 7.—Taken by G Platania from the north north-east of the craters, July 30, 1892. (1) Crater No 1 (c) Craters which were in activity only on July 9. The craters No 2, 3, and 4 are hidden behind crater No. 1

farther off at Catania and Acireale we heard the rattling of the windows and doors, which, strongly shaken,

[1] G Platania "Stromboli e Vulcano, nel Settembre del 1889. Riposto 1889." This phenomenon I have often observed at Vesuvius, and I quite agree with Signor Platania as to its cause, as I have been able to look in the crater and watch the whole process.—Johnston-Lavis.

[2] The lava in this case is very like the boiling up of a viscous liquid in a long test-tube.—Johnston-Lavis.

[3] I have some doubts about the two mechanical disturbances travelling exactly at the same rate. When blasts are fired in a long tunnel the air-stroke is felt before the sound.—Johnston-Lavis.

give the impression of an earthquake, so that several times the people of these towns have rushed out into the streets On July 14 I observed in Acireale that the large undulations of the air-blows which were propagated beyond 333 m per second, like sonorous vibrations, often arrived unaccompanied by noise, and strongly shook doors and windows

These reports, these air-blows, and the abundant ejection of incandescent lava still further prove that in No 2 crater there was pasty lava which swelled and burst, as we deduced from its effect on the white vapours

This period of great activity, in which the thick shower of lava fragments projected from the different craters to great heights and spread over an area of 500m radius, reached its maximum about midnight, and then gently declined a little In the same manner the eruption continued during the following days with great energy, but with a very gradual diminution in its intensity, interrupted more or less by strong spasms The lava continued to advance, but diminished in velocity, while it extended in breadth and depth The eastern branch very soon stopped, and also the western one, after having continued its destruction of very fertile ground This having crossed the road known as the St Leo, finally

Monte Nero Crater No 4 Crater No 3 Crater No 2 Crater No 1

FIG 8 —Taken by G Platania on July 30 from the north east of the craters. No 4 is still very little, but in part hidden behind a prominence of the ground

stopped, whilst the new lava that continues to issue forms new ramifications and flows, which pass quite close to the earlier ones, and now actually are in contact with them, increasing the area covered In the first paroxysm of the eruption the lava issued in great gushes all along the rift Soon at the upper part commenced the dejection cones, and lower down the fire vents, and the lava flowed in abundance, and with explosions also in points where now are the craters, as, for example, Nos 3 and 4 Later, when the explosive force had diminished, the lava issued without explosions, almost silently from different vents at the south end of the fissure on which are aligned the craters These vents, therefore, have during the eruption varied in number and form Some have assumed the function of dejection craters as occurred in Nos 3 and 4, which gave passage to much lava as a current Others have ceased to eject scoria, to send forth only torrents of lava, as, for example, the little mouth to the east of No 4, the scoria rim of which exists only to the north, of about 20m high, whilst the south rim has been swept away by the current Some of the mouths have been refilled by the lava flows, and whilst some have become extinct new ones have been formed

In the last week of July, crater No. 2 assumed, for some days, a new phase Its explosions had become rare, long, and very grand, and the large mass of vapour, mixed with dust, brought back to my mind the eruption of Vulcano when we stood on the crater edge and watched and photographed the whole process, and stood our ground amidst showers of bombs and other projectiles (1888–90)[1] By this it lost the beautiful regular truncated cone form that it had at the beginning, and became irregular and broken-down towards the north, like No 1

At the commencement of August the eruption already seemed much diminished, craters No 1 and 2 had ceased to eject stones little by little, gradually becoming blocked, and the enclosed lava was slowly cooling In fact, on the recommencement of a period of renewed energy, the explosive force could no longer find an escape by them, so that on August 1 a new crater opened in a point higher up where the cleft to the west, which had only acted at the commencement of the eruption, joined another great rift on which the craters were formed Then on August 9 occurred another violent eruptive spasm, which could not clear away the material that obstructed the craters, but opened a new way, always on the main cleft, between Nos 1 and 2, and exactly at the north base of the last of these craters Here a little funnel-shaped depression was formed which for a short time ejected enormous masses This new crater, however, soon passed into the solfataric stage as Nos 1, 2, and 3, and there remained in an energetic state of activity only the crater of August 11 and No 4 That one which on August 21 measured in diameter only about 50 m, and had a height of about 60 m, later became elongated towards the S S W, and its grand and beautiful explosions, which I watched quite closely, in company with Mr Rudler, on August 29, 30, and 31, were specially localized on the southern edge, so that they tended all the more to give it an elongated form on that more western cleft that was only in activity the first days of the eruption No 4, meanwhile, which I approached, ascending upon No 3, gave forth frequent eruptions of hot lava cakes at regular intervals (about fifty per minute), accompanied by globes of yellowish vapour, and a noise similar to that which accompanies the globes of vapour from the locomotive when it commences to move

By unanimous consent of all the studious inhabitants of Etna, the new craters have been called the Monti Silvestri, in honour of that well-known vulcanologist, the lamented Prof Orazio Silvestri, who studied our volcano with so much fervour, registered so assiduously every slight disturbance, and described its paroxysms so well and with such originality, that his loss has been deeply felt by all men of science GAETANO PLATANIA

14, Via S Giuseppe, Acireale,
September 7

NOTES

THE Harveian oration will be delivered by Dr J H Bridges at the Royal College of Physicians on Tuesday, October 18, at four o'clock

THE Medical Session in London was opened on Monday, and introductory addresses were delivered in some of the schools attached to hospitals A particularly interesting and suggestive address was delivered at the Westminster Hospital by Dr Mercier, who dealt with various aspects of the problems connected with crime, pauperism, and insanity Sir John Lubbock addressed the students at St Thomas's Hospital

ON Friday last Sir George Murray Humphry, F R S, delivered an interesting address at the opening of the first session

1 "South Italian Volcanoes," by Johnston Lavis, Naples, 1891 "I Projettili Squarciati di Vulcano," by G Platania. (Roma 1891)

of the Queen's Faculty of Medicine in connection with Mason College, Birmingham. The union of the two institutions is likely to be of great service both to medicine and to pure science in the Midlands.

A MARINE biological station has been established at Bergen, in Norway, the funds having been raised by private donations and by subscriptions from learned societies. It will be under the control of Dr. J. Brunchorst, and will supply ten places for Norwegian and foreign workers.

WE regret to learn that M. Henri Douliot, who had been commissioned by the French government with a botanical expedition to the western coast of Madagascar, has died there of fever.

DR. B. L. ROBINSON has been appointed Curator of the Herbarium of Harvard University, Cambridge, U.S.A., in succession to the late Prof. Serreno Watson.

MR. WALTER L. COLLINGE, late Assistant Demonstrator in Zoology in St. Andrew's University, has been appointed to the vacant Demonstratorship in Zoology and Comparative Anatomy and Botany in Mason College, Birmingham.

A CIRCULAR appeal, dated September, 1892, and signed by Mr. E. C. Pickering, Director of the Observatory of Harvard College, has been issued, inviting the wealthy to consider the opportunity offered for a donor of 200,000 dollars "to have his name permanently attached to a refracting telescope, which, besides being the largest in the world, would be more favourably situated than almost any other, and would have a field of work comparatively new." The telescope in question would be placed in the station established by Harvard College Observatory, near Arequipa in Peru, at an altitude of more than eight thousand feet. "During a large part of the year," says Mr. Pickering, "the sky of Arequipa is nearly cloudless. A telescope station having an aperture of thirteen inches has been erected there, and has shown a remarkable degree of steadiness in the atmosphere. Night after night atmospheric conditions prevail which occur only at rare intervals, if ever, in Cambridge. Several of the diffraction rings surrounding the brighter stars are visible, close doubles in which the components are much less than a second apart are readily separated, and powers can be constantly employed which are so high as to be almost useless in Cambridge. In many researches the gain is as great as if the aperture of the instrument was doubled. Another important advantage of this station is that, as it is sixteen degrees south of the equator, the southern stars are all visible." The circular continues: "The planet Mars, when nearest the earth, is always far south. The study of the surface of this and of the other planets is greatly impeded by the unsteadiness of the air at most of the existing observatories. Even under the most favourable circumstances startling discoveries—relating, for example, to the existence of inhabitants in the planets—are not to be expected. Still, it is believed that in no other way are we so likely to add to our knowledge of planetary detail as by the plan here proposed." We venture to hope that the wealthy donor for whom Harvard is looking will soon be found.

BARON LEON DE LENVAL, of Nice, offers a prize of 3,000 francs to the inventor of the best application of the principles of the microphone in the construction of a portable apparatus for the improvement of hearing in deaf persons. Instruments for competition should be sent to Prof. Adam Politzer, or Prof. Victor von Lang, Vienna, before December 31, 1892. The prize will be awarded at the Fifth International Otological Congress at Florence in September, 1893. If no instrument is judged worthy of the prize, the jury reserve the right of announcing another competition, unless Baron Lenval decides to dispose of the prize otherwise. The following are the members of the jury:—Prof. Adam Politzer (President), and Prof. Victor v. Lang, Vienna; Dr. Benni, Warsaw; Dr. Gellé, Paris; Prof. Urban Pritchard, London; Prof. St. John Roosa, New York; Prof. Grazzi, Florence.

THE weather during the past week has been much disturbed by several depressions, which have caused heavy rainfalls over the whole of the kingdom, with hail and thunderstorms in many places. On the morning of September 30 the amount of rain measured on the south coast was an inch and a half, or about half the average for the month; and on the west coast, especially at Liverpool, much damage has been done by floods, occasioned by the excessive amount of rain. Temperature has been low for the season, the daily maxima rarely exceeding 60° in any part of the country, while in the north and west the readings have been much lower; frost has been recorded in the shade in the east of London, and the nights have been very cold generally. For several days a cyclonic area was situated over the United Kingdom, and strong winds were experienced on some coasts; a temporary improvement, however, occurred on Tuesday, although conditions remained very unstable. The *Weekly Weather Report* of the 1st inst. shows that the rainfall was in excess everywhere. In the south-west of England it amounted to 1.2 inch; but there was still a deficiency of 7½ inches since the beginning of the year. The temperature was below its mean value in all districts except the south of England and the Channel Islands, the deficiency being greatest in Scotland and Ireland.

SOME results of seven years' meteorological observations on the Pic du Midi, at a height of about 9500 feet, have been recently published by M. Klengel. The annual mean temperature is $-2°.2$ C. The annual variation, $14°.3$, is only one degree less than at Tarbes on the plain, and is about that of the Sonnblick (which is some 800 feet higher than the Pic). April is abnormally cold ($-6°.2$), and this is attributed to the fact that the Pic stands in Van Bebber's fifth depression-path, which is most frequented in that month. While Pip's Peak represents the extreme continental type of high mountain climates, and Etna the oceanic type, in nearly the same latitude, the Sonnblick and the Pic du Midi represent transition types. The maximum zone of precipitation on the Pic lies at about 7700 to 8000 feet; above this there is marked diminution. The results in general show that even at a height of nearly two miles the distribution of land and water on the earth's surface has a considerable influence on climate.

A SHOCK of earthquake, lasting from three to five seconds, was felt at Huelva, between twelve and one o'clock on the morning of September 29. According to a Reuter telegram, three shocks were noticed, the first being weaker than the succeeding disturbances. The direction of the seismic wave was taken from north to south, and the subterranean rumblings were heard very distinctly over a large area. The inhabitants were greatly terrified, but nobody was injured. Many windows were smashed, but beyond this the damage was insignificant.

A CURIOUS instance of globular lightning is referred to in the *Meteorologische Zeitschrift* for September 1892. On August 7, during a thunderstorm at Altenmarkt, near Fürstenfeld, while the priest was administering the sacrament, the church was struck by lightning, followed by a loud explosion. A panic immediately ensued, and the congregation rushed out, notwithstanding the assurances of the priest that there was no danger. There was nothing to show how the lightning entered the church, but it is supposed it was by the conductor leading from the steeple. It is said to have been a large globe, tapering towards the upper part, and after the explosion it left a strong sulphurous smell. The explosion was very loud and shook the building.

The last number of the *Berichte der Deutschen Botanischen Gesellschaft* contains an interim report on the progress of the negotiations concerning the nomenclature of genera, started by a committee of botanists at Berlin to supplement the decisions of the International Botanical Congress held at Paris in 1867. The proposals submitted last April to the consideration of 329 German and Austrian and 377 foreign botanists were the following:—(1) The year 1752 to be taken as the initial date for priority in names of genera, and 1753 for the names of species. (2) Nomina nuda and semi nuda to be rejected. Drawings and dried specimens without diagnoses to establish no claim to priority of a genus. (3) Similarly sounding generic names to be retained, even if differing only in the ending or by a single letter. (4) The names of the subsequent great or well-known genera to be preserved, even if they ought to be rejected by the strict rules of priority, especially in cases where no change in the names used up to the present can be proved. 360 replies had been received up to the time of the report, amongst them being 157 from Germany, 63 from Austria, and 19 from Great Britain and Ireland. The great majority expressed approval, at least, of the first three proposals. The botanical authorities of the British Museum favour the suggestions, those at Kew are against them.

M. G. Trouvé has built a luminous fountain for Mme. Patti, at her residence at Craig-y-Nos, an account of which appears in No. 11 of the *Comptes rendus*. "The weight of this fountain is about 10,000 kgr., and the basin measures 6 m. in diameter. The illuminating power is represented by four incandescent lamps of 110 volts, each consuming 6 amperes. Thus the total electric energy amounts to 2640 watts; this gives, at three watts per candle, a light intensity of over 800 candles. The lamps are centred at the focus of four parabolic reflectors grouped under the glass chambers whence the water springs. As in the chamber fountains, the metallic ajutages, which would have cast shadows, are eliminated. The water which falls from the upper to the lower basin is utilised to drive a small bucket-wheel, which governs the rotation of two superposed discs, concentric or otherwise, made of coloured glasses, which turn in the same or in the opposite sense, with equal or unequal velocities as required, between the reflectors and the glass. This combination of two discs with opposite rotations renders possible a variation in the play of colours of the liquid sheaves, which succeed each other with the unexpectedness of the kaleidoscope. The motive power can be chosen at pleasure. It may be hydraulic, electric, or by clockwork, of forms and dimensions in keeping with the character of the decoration. These fountains need neither expenses of installation nor costs of maintenance, and their price depends solely upon their artistic perfection and their importance. Hitherto the construction of luminous fountains has only been hindered by the impossibility of sufficiently illuminating the jets. To-day the problem is reversed. Since the light can be projected without sensible loss to great heights, the only difficulty will be to give a sufficiently high pressure to the water."

The Manchester Field Naturalists' and Archæologists' Society closed the out door session by a visit to Buxton on Saturday, September 24. The field meetings were well attended during the session, and the introduction of an itinerary for each excursion, detailing the natural history features of the district, was of service. The president, Mr. Charles Bailey, F.L.S., usually gave the address upon the botanical specimens observed. At Buxton, the chairman of the directors of the Winter Gardens conducted the party through the grounds, and undertook to convey to his colleagues the desire of the Society that the county ferns and native phanerogams, so far as they will live at the altitude of the gardens, which are a thousand feet above the sea, should be introduced.

At a meeting of the Norfolk and Norwich Naturalists' Society, held in the Norwich Museum on September 27, Mr. Southwell exhibited, by permission of Mr. T. Ground, of Moseley, Birmingham, a Siberian pectoral sandpiper (*Tringa acuminata*), killed at Yarmouth by that gentleman on August 29, which he believed to be the first European example of this bird hitherto recorded.

The administrative report of the Marine Survey of India for the official year 1891-92 has been published. Dr. A. Alcock, Surgeon-Naturalist to the Survey, shows that in his department the year has been by no means unproductive. He expresses his belief, however, that the results would be tenfold greater, both from the scientific and from the economic points of view, if, in the survey of inhabited coasts, the naturalist could follow the ship from camp to camp ashore, visiting it at short, convenient intervals for medical purposes, but otherwise devoting all his time to systematic exploration of the grounds worked by the fishermen—grounds of marvellous richness still quite unexplored and unappreciated.

Among the animals Dr. Alcock has specially observed is the red ocypode crab, which swarms on all the sandy shores of India. The bigger of its two chelæ, or nippers, bears across the "palm" a long finely-toothed ridge, and on one of the basal joints of the "arm," against which the "palm" can be tightly closed, there is a second similar ridge. When the "palm" is so folded against the base of the "arm," the first ridge can be worked across the second, like a bow across a fiddle, only in this case the bow is several times larger than the fiddle. The remarkable resemblance of the whole arrangement to the stridulating apparatus of many insects led Prof. Wood Mason some time ago to infer a similarity of function, and he asked Dr. Alcock to observe the crabs, and to listen for the sounds which he supposed them to be capable of making. Dr. Alcock is now able to give facts which establish the truth of Prof. Wood Mason's idea. The sounds can be heard, and their effects seen, if one crab, which may be called the intruder, is forced into the burrow of another, which may be called the rightful owner. The intruder shows the strongest reluctance to enter, and will take all the risks of open flight rather than do so, and when forced in he keeps as near the mouth of the burrow as possible. When the rightful owner discovers the intruder he utters a few broken tones of remonstrance, on hearing which the intruder, if permitted, will at once leave the burrow. If the intruder be prevented from making his escape, the low and broken tones of the rightful owner gradually rise in loudness and shrillness and frequency until they become a continuous low-pitched whirr, or high-pitched growl, the burrow acting as a resonator. Dr. Alcock concludes that the use of the stridulating organ appears to be that a crab, when it has entered its burrow, may be able, by the utterance of warning notes, to prevent other crabs from crowding in on top of it.

Dr. Fritz Noetling has been investigating the amber and jade mines of Upper Burma, and sets forth the results of his inquiry in the new number of the Records of the Geological Survey of India. The strata in which the amber is found belong to the tertiary formation, probably to the lower miocene. Dr. Noetling does not think that Burmese amber would be received with much favour in Western markets—first, because it does not include the milky-white, clouded variety which has for a long time been so much appreciated in Europe; second, because of its fluorescence. This is the bluish tinge which appears when the amber is looked at under a certain angle—a tinge which is sometimes so strong that fine yellow pieces seem to be of an ugly greenish colour.

Dr Noetling has formed a higher idea of the value of the jade mines of Burma There are two different groups of jade mines—pit and quarry mines The former are situated along the bank of the Uru river, beginning at about Sankha village, and extending for a distance of about forty miles farther down The quarry mines near Tammaw village are situated eight miles west of the Sankha village, on the top of a plateau rising to about 1,600 feet above the level of the Uru river The Tammaw mines afford the best opportunity for the study of the geological conditions under which the jade is found It there forms a vein of considerable thickness in an igneous rock of blackish-green colour The jade is a purely white crypto crystalline mineral, much resembling the finest marble, containing here and there green specks of various sizes, which form the jade proper The jade vein is separated from the black rock by a band of a soft and highly decomposed argillaceous mineral The strike of the vein is approximately north to south, and the dip at about an angle of 20°, varying considerably towards east There are at least 500 men engaged every season in working the quarry mines at Tammaw The mining operations are carried on in the rudest fashion No blasting powder being available, the rock is heated by large fires, and, having cooled down, is broken in pieces by means of enormous iron hammers The operations in the pit mines are less difficult The miner simply digs a pit and selects boulders of jade from the stuff dug out. Good pieces of jade are sometimes found in the laterite, which forms beds of varying thickness along the Uru These pieces have superficially undergone a certain discolouring in such a way that the original green or white is changed under the influence of the hydrated oxide of iron into a dark red colour Specimens of this kind are generally known as "red jade" Dr Noetling says that the jade mines form a most valuable property He has no doubt that besides the Tammaw jade vein others will be discovered We know now that jade is intimately associated with a dark igneous rock (trap), and Burma abounds in rocks of this kind

Mr Otis T Mason contributes to the latest report of the U S National Museum (for 1890) an interesting study of the ulu, or woman's knife, of the Eskimo The ulu is found throughout the Eskimo region, from Labrador to Kadiak, and consists of a blade and a handle or grip with or without some form of lashing The blade is either a thin piece of slate ground to an edge, a bit of cherty or flinty rock chipped to an edge, a scrap of steel or iron from wrecks of whaling vessels, or good blades made and sold to the Eskimo by traders who visit their country The handle varies greatly in material, form, and finish In form alone the specimens from each typical area are unique Some of the ulus in the U S National Museum are as coarse as savagery could make them, others are very beautiful The same locality furnishes both and intervening kinds, but some areas supply only coarse work The problem has to some extent been complicated by white influence. The ulu has survived in civilized countries under two well known forms—the saddler's knife and the kitchen knife The saddler thus perpetuates, for cutting leather, an implement designed to be used with skins from which the hair has not been removed The kitchen chopper is the woman's knife deprived of nearly all its ancient and primitive offices, consigned to a single one, which it scarcely had at the beginning The saddler's knife may be seen in the hands of leather-cutters represented on Egyptian monuments An excellent series of illustrations, grouped in accordance with the regions from which the specimens come, adds greatly to the interest and value of Mr Mason's paper

It is a common experience in daily life that milk has in itself little or no tendency to putrefaction, and that it may even to some extent preserve certain substances that are readily decomposed, such as meat This property has lately been investigated by Herr Winternitz, in Strasburg Of the three chief constituents of milk, viz., casein, fat, and milk sugar, the first proved as liable to putrefaction as the meat or pancreas extract experimented with, the fat, too, had no preservative influence Milk-sugar, on the other hand, in accordance with what is known regarding the power of carbohydrates to retard putrefaction, acted as strongly as cane-sugar Nothing definite was ascertained as to the nature of this action It was proved, however, to take place in the alimentary canal as well as outside of the system

Rats at Milnthorpe, Westmoreland, seem to have found a fresh outlet for their predatory impulses Mr G Reade, in a letter quoted in the new number of the *Zoologist*, says that the ripe gooseberries in his garden there were disappearing very rapidly this year, and he supposed that the mischief was being done by blackbirds However, his attention was called to a large rat taking the berries off with his mouth and dropping them to other rats below Presently another climbed the tree and helped to gather the berries In a little time both came down, each with a berry in its mouth, having a curious appearance Mr Reade saw the performance several times repeated Then he placed a wire cage under the tree, and in three days caught nine of the intruders

The electric light seems to have an extraordinary attraction for lepidoptera On August 19, as he records in the new number of the *Entomologist*, Mr D S Stewart had an opportunity of noting this fact At the Eddystone lighthouse exhibited in the Botanic Gardens at Old Trafford (the same lighthouse as was shown at the Naval Exhibition), he saw great numbers of moths Before ascending, he says, one could see them from below, flashing in and out of the rays in hundreds, and when the top was reached, the place was found to be full of them—"some, apparently dazzled by the light, frantically flying in all directions, buzzing and banging in your face, up your sleeves, down your neck, everywhere In every sheltered niche and cranny four or five were to be seen together, and especially was this so on the staircase, which was strewn with their partially cremated remains, the result of their all too successful attempts at self immolation"

A valuable paper on the breeding habits, eggs, and young of certain snakes, by O P Hay, is printed in the latest volume (xv) of the Proceedings of the U S National Museum, and has also been issued separately Mr Hay notes that, although serpents have made a deep impression on the human mind, very little accurate information has been accumulated concerning some of their habits His paper embodies the results of a good deal of careful personal observation

The Nova Scotian Institute of Natural Science has changed its name to the Nova Scotian Institute of Science, and has secured an Act of Incorporation It has now begun the second series of its "Proceedings and Transactions," the first part of vol i having just been issued Among the papers in this part are "Notes on the surface geology of South Western Nova Scotia," by Prof. L W Bailey, "Steam boiler tests as a means of determining the calorific value of fuels," by D W Robb, "Analyses of Nova Scotia coals and other minerals," by E Gilpin, jun, "The Magdalene Islands," by the Rev Dr G Paterson, "Notes for a Flora of Nova Scotia," Part I by Prof G. Lawson

Messrs. Williams and Norgate are about to publish a work entitled the "Cry of the Children," by "Free Lance." It deals with education in a wide sense, but more especially it advocates the necessity of a scientific training

PART I of a new work on practical physics, by Prof W F Barrett, of the Royal College of Science for Ireland, will shortly be published by Messrs Percival and Co It will treat of physical processes and measurements, and the properties of matter

THE University Correspondence College has issued its calendar for 1892 93 The Principal, in his report, shows that the college has been in many ways remarkably successful

THE calendar of the Imperial University of Japan for 1891 92 affords ample evidence that the authorities of this important institution are doing everything in their power to secure that it shall meet the needs of the present age We may note that in the college of science the following seven courses, each of which extends over three years, have been established Mathematics, astronomy, physics, chemistry, zoology, botany, and geology

IN the last sentence of the fourth paragraph of Lord Kelvin's article on "Generalization of Mercator's Projection Performed by aid of Electrical Instruments" (NATURE, September 22, p 491), for "three" read "two" For corrections in paragraph 3, and in the last paragraph but one, see article "To Draw a Mercator Chart, &c," in the present issue

AN interesting new compound, the silver salt of the little known imide of sulphuric acid, SO_2NAg, has been obtained by Dr Wilhelm Traube, in the laboratory of the University of Berlin, and an account of its properties, together with a considerable amount of fresh information concerning both the amide and imide of sulphuric acid, are contributed by him to the current number of the *Berichte* Regnault long ago obtained a solid substance, which he regarded as a mixture of the neutral amide of sulphuric acid $SO_2(NH_2)_2$ with ammonium chloride, by leading ammonia gas into a solution of sulphuryl chloride SO_2Cl_2 in ethylene chloride

$$SO_2Cl_2 + 4NH_3 = SO_2(NH_2)_2 + 2NH_4Cl$$

The separation of the two substances, however, was but imperfectly effected, so that our knowledge of the amide itself is very vague Dr Traube now shows that the amide may be isolated without difficulty by the following process The sulphuryl chloride is dissolved in fifteen times its volume of chloroform, which exerts no chemical action upon it, and dry ammonia gas is led through the liquid until the latter becomes saturated The products of the reaction separate during the passage of the gas in the form of a white solid The whole product is then agitated with water until the precipitate dissolves, the aqueous solution is separated from the chloroform and afterwards boiled in contact with oxide of lead or silver until all chlorine is removed from it Upon filtering and evaporating the resulting liquid a syrup is eventually obtained, which only crystallizes with difficulty and would appear to consist of neutral sulphamide $So_2(NH_2)_2$ It is an extremely deliquescent substance whose solution in water and dilute acids is not precipitated by salts of barium or by platinic chloride Only after prolonged boiling with hydrochloric acid does decomposition occur with the gradual deposition of barium sulphate The effect of boiling in the presence of acids would appear to be its conversion into ammonium sulphate Sulphamide possesses the power of combining with the oxides of mercury, lead, and silver, to form white solid substances Thus if mercuric nitrate, lead acetate, or ammoniacal silver nitrate are added to the aqueous solution of the amide these white solid compounds are precipitated The mercury compound is insoluble in dilute nitric acid, while the lead and silver compounds are readily soluble, forming solutions which are perfectly indifferent to barium salts It was from the compound containing silver that the interesting silver imide was obtained Upon heating the silver compound to the temperature of 170–180° until ammonia ceases to be evolved, and extracting the residue with hot water feebly acidified with nitric acid, the new compound SO_2NAg separates upon cooling in long acicular crystals Analyses have proved its composition to be that stated, and from its reactions it must be regarded as being the silver salt of sulphimide SO_2NH The crystals are only soluble with difficulty in cold water, but more freely in hot water and readily in dilute nitric acid The solution is not precipitated by barium nitrate Even after removal of the silver by means of hydrochloric acid barium salts yield no precipitate, indeed, it requires long boiling with concentrated acid to effect any precipitation It would appear that the solution left after removal of the silver contains sulphimide itself, and Dr Traube is continuing his experiments with a view to the isolation of the latter compound

THE additions to the Zoological Society's Gardens during the past week include a Grivet Monkey (*Cercopithecus griseoviridis* ♀) from South Africa, presented by Mr W. Howard a —— Lark (*Alauda coelivox*) from China, presented by Mr Gervase F Mathew, R N, F Z S, two Common Kestrels (*Tinnunculus alaudarius*), British, presented by Mr L Bergasse a Herring Gull (*Larus argentatus*), British, presented by Mr H H Johnson, a Tuatera Lizard (*Sphenodon punctatus*), from New Zealand, presented by Capt G Eriksen, four Smooth Snakes (*Coronella laevis*) British, presented by Mr E Penton, F Z S, six American Green Frogs (*Rana halecina*), four Noisy Frogs (*Rana clamata*), from Canada, purchased, one Concave casqued Hornbill (*Dichoceros bicornis*), from India, received in exchange, three Wild Swine (*Sus scrofa*) born in the Gardens

OUR ASTRONOMICAL COLUMN

COMET BROOKS (AUGUST 27, 1892) —*Astronomische Nachrichten*, No 3119, contains the elements and ephemeris of Brooks's comet calculated by F Ristenpert, assuming an elliptical orbit and the unit of brightness on August 31 5 as the unit of Br —

Elements

Nova Aurigæ —In some further notes that we have referring to the brightness and the spectrum of the Nova, we find that most observers estimate the star's magnitude to lie between 10 and 10 5 Herr Belopolsky, who has examined the star spectroscopically, has been able to see one or two lines, a later estimation of the brightest gave a wave length of 501, while the second line proved too variable in brightness to allow of a sufficiently correct mea urement

To *Astronomische Nachrichten*, No 3118, Mr H Seelinger contributes a very important article, in which he suggests an hypothesis which may be said to approach that put forward by Mr Lockyer some time ago He assumes (and a very fair assumption too) that the cosmos contains innumerable more or less elongated forms of very thin and small particles, and that the Nova was produced by a body rushing into one of these, so to speak, clouds On entering this cosmical cloud, at once there would be a condition for producing heat, and therefore light, and we have only to imagine the cloud to be of varying thicknesses to account for the peculiar fluctuations which attended the light of the Nova That such a case should take place seems in itself more probable than that of two bodies passing very near one another, and we already know that such streams as suggested do exist Our November shower, for instance, is such a swarm, only on a scale very much smaller than that inferred above

GEOGRAPHICAL NOTES

Until recently the Samoan calendar corresponded with the Australian, but on July 4 last a change was made by order of King Malietoa Tuesday, July 5, was reckoned a second time as Monday, July 4, thereby coming into harmony with the American and European reckoning Samoa, lying to the east of 180°, had retained the old system of time, superseded by the general acceptance of that meridian as the line at which the date is rectified by vessels at sea

Captain Lugard reached London from Uganda on Sunday night It is gratifying to know that his three years' residence in equatorial Africa, and the severe strain of recent events, have not told adversely on his health He will probably communicate the important geographical results obtained by him to a special meeting of the Royal Geographical Society in November

The arrangements for the next session of the Royal Geographical Society present several new features In addition to the ordinary meetings it is proposed to give a special series of Christmas lectures to young people, to be followed by a course of ten weekly educational lectures, specially adapted for teachers, by Mr H J Mackinder The ordinary meetings as provisionally arranged begin on November 14 by a paper on his proposed North Polar expedition by Dr Nansen Mr Joseph Thomson will follow with an account of his expedition to Lake Bangweolo Captain Bower will describe his journey across Tibet, and Captain Lugard will recount his discoveries in equatorial Africa Prof Milne and Mr Savage Landor have promised papers on Yesso, Major Rundell on the Siyin Chins, Mr H O Forbes on the Chatham Islands, and Captain Gallwey on Benin It is hoped that Mr Conway will return to describe his adventures in the Karakoram mountains Apart from the records of travel to which the attention af the Society in its ordinary meetings has usually been mainly devoted, there will be papers dealing with the more general and scientific aspects of Geography The Prince of Monaco will probably describe his experiments on the Atlantic currents, Sir Archibald Geikie will lecture on types of scenery, Prof Bonney on the work of glaciers, Mr J Y Buchanan on the windings of rivers, and Dr Schlichter on his new photographic method of determining longitude

The last number of *Petermann's Mitteilungen* contains an important paper by Dr Alois Bludau giving the co-ordinates for Lambert's equivalent area azimuthal projection of the map of Africa An outline of the continent on this projection, the central point of which is on the equator in 20° E long., shows the remarkable suitability of the map for representing Africa, the distortion being inappreciable

MAGNETIC INDUCTION[1]

The lecturer remarked that it was no less than forty-five years since the magnetic properties of materials had formed the subject of an evening discourse before the British Association At the Oxford meeting in 1847 the lecturer was Michael Faraday, who had only a little while before made his great discovery of diamagnetism and been led to the splendid generalization that all substances are in one way or other, and in greater or less degree, susceptible of magnetic influence And it was an interesting coincidence that in the same year, partly indeed at that same Oxford meeting of the Association, the foundation of the modern mathematical treatment of magnetism had been laid by that infant phenomenon, whom in the vigour of his maturity we were now learning to call Lord Kelvin Discarding the arbitrary hypotheses of earlier theoretical writers, Lord Kelvin, then a stripling at Cambridge, had proceeded to give mathematical expression to the observations and intuitions of Faraday In recent years the science of magnetism had advanced fast, keeping pace with the advance of its industrial applications In common with other branches of electricity it had discovered the advantage of being useful The debt which practice owed to science had been repaid with interest In other departments of science it might be true that there were devotees whose chief pride in their work lay in their reflection that it could never be of any use to anybody this temper of mind was not possible to an electrician The language of electricians had passed with bewildering rapidity into Acts of Parliament and provisional orders of the Board of Trade, and the demands of industry had stimulated discovery and fostered exactness in measurement It was the beneficent reaction of practice on science that had enabled the great work of the Electrical Standards Committee of the British Association to be brought to a successful issue As a fruit of that work electricians were in high hope that this Edinburgh meeting would result in an international agreement with regard to the electrical units, so that whatever the Great Powers might find to differ about they would at least be of one mind as to the magnitude of the volt, the ampere, and the ohm In the co operation of Prof von Helmholtz on the part of Germany, and of M Mascart on the part of France, with Lords Kelvin and Rayleigh and their English colleagues, there were surely the elements of a Triple Alliance which should secure to the electrical world peace, not only with honour, but with precision

The lecture of Faraday in 1847 had dealt with the condition induced by magnetic force in matter which was not ordinarily magnetic Substances were broadly divisible into two classes, those which were strongly susceptible to magnetic influence and those that were only very feebly susceptible The latter was by far the most numerous class, and it was with it that Faraday dealt in his lecture The strongly magnetic substances were iron and its various derivatives, which passed by the general name of steel, also nickel and cobalt A recent discovery by Prof Dewar seemed to require that oxygen, in the liquid state, should be added to this list The lecturer proposed to confine his attention to the phenomena of magnetization which were exhibited by the strongly magnetic metals Let any one of these metals be submitted to the action of a magnetizing force such as would be produced if an electric current were passed through a coil of insulated wire surrounding the metal As the current was gradually increased, the magnetization passed through three stages It began very gradually, at first, while the current was still weak, there was but little magnetism developed Then a stage came on in which the magnetic state was acquired with great rapidity; a small increase in the current now caused an enormous gain of magnetism Finally, the process passed into a third stage, when the magnetism was again acquired slowly, and however much the magnetizing current was increased it was found to be impossible to force the magnetism to exceed a certain limiting value This was the phenomenon of magnetic saturation Recent researches had given definiteness to the rather vague idea which used to be expressed by this phrase, and it was now known not only that a limit existed, but what its values were in the several magnetic metals The lecturer illustrated the three stages in the magnetizing process by means of the lantern, exhibiting curves which showed the connection between mag-

[1] Abstract of an evening lecture delivered before the British Association, at Edinburgh, August 8, 1892, by J A Ewing, M A, F R S, Professor of Mechanism and Applied Mechanics, Cambridge University

netism and magnetizing force, and pointed out that in special cases the three stages became extraordinarily distinct Curves of the same kind were used to show what happened after a magnetizing force had been applied, if it were withdrawn or varied in any way The magnetism in all cases tended to lag behind when the magnetizing force was varied, and hence these curves in any cyclic process became loops enclosing a certain area It had been proved that this area served to measure the energy expended in carrying the substance through a cyclic magnetizing process, the reason why energy had to be spent being the tendency which the magnetism always had to lag behind the force that was operating to change it To this tendency he had given the name "hysteresis," a term which was already of formidable significance in the ears of practical electricians For the existence of hysteresis was the chief reason why the transformers which were used in alternate current systems of electrical distribution absorbed wastefully a considerable amount of power The iron core of a transformer was being carried through a cycle of magnetization from a positive to a negative value and Weber postulated an arbitrary directing force, which tended to hold them in their original direction The lecturer proceeded to show by means of experiments conducted on the projecting table of the lantern, and shown on a large scale on the screen, that no arbitrary directing force was necessary The mutual actions of the molecular magnets on one another supplied all the control that was required It accounted completely for the three stages of the magnetizing process and for all the phenomena of hysteresis It accounted also for the effects which were found to be produced by mechanical vibration and mechanical strain Experiments were made exhibiting the breaking up of molecular groups, bound together by their mutual forces, under the influence of a gradually increased external directing force In these experiments models were used, consisting of a number of small magnets, pivoted like compass needles on fixed centres, and arranged on the horizontal table of a large projecting lantern A pair of coils placed one on either side of the group supplied deflecting force, and as the current in these was gradually increased the three stages of the magnetizing

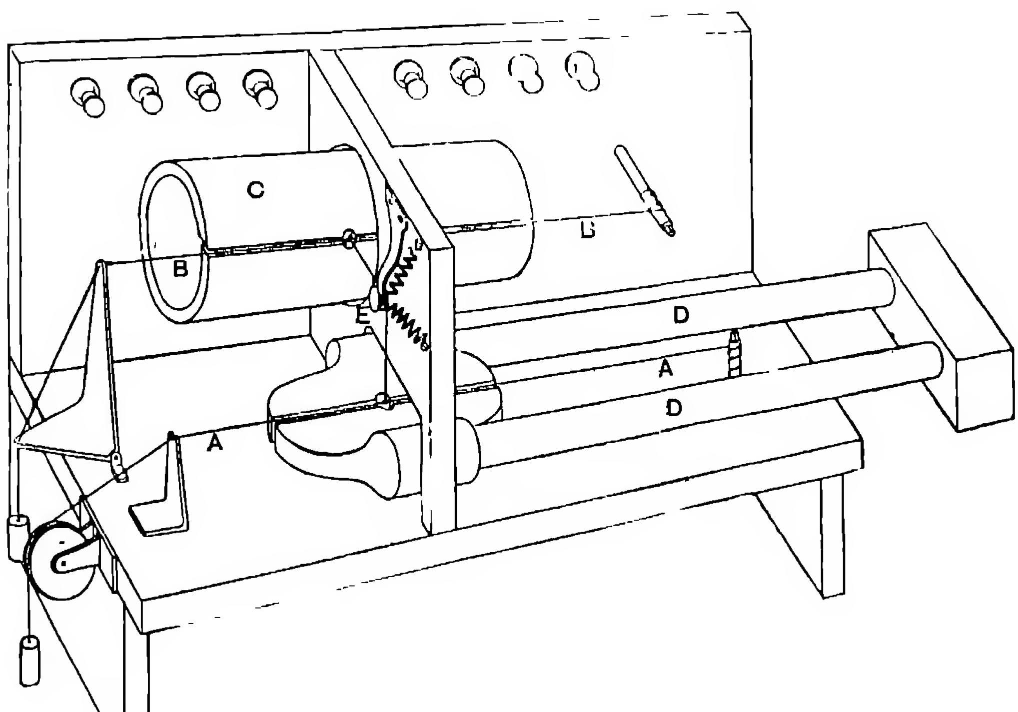

FIG 1 —Prof Ewing's Magnetic Curve Tracer General view of apparatus

back again some 80 or 100 or 120 times a second, and every one of these periodic reversals of magnetism implied a waste of energy, which went on even when no useful current was being drawn off It was a question of considerable practical interest, whether the amount of work wasted on the iron of a transformer was the same per cycle at high speeds of reversal such as were usual in practice, as it was in the slow speed laboratory experiments, by the help of which these cyclic curves had been drawn

The lecturer proceeded to give some account of molecular theories which had been framed to account for the characteristics of the magnetizing process It was suggested, originally by Weber, that the molecules of iron are always little magnets, and that when the iron, as a whole, is not magnetized, it is because as many of the molecular magnets are facing one way as another According to this view the process of magnetization consists in turning the molecular magnets round, so that they face, more or less, one way When a very strong magnetising force is applied, the molecules are forced all to face one way, the piece is then saturated To explain why they did not at once turn round completely when any magnetizing force was applied, process and the phenomena of hysteresis exhibited themselves in the manner in which rearrangement of the elementary magnets composing the group took place In some of the models the magnets turned under water, so that their vibrations were rapidly damped out Slides were also shown which gave some of the results of observations recently made in the lecturer's laboratory by Miss Klaassen, of Newnham College, which demonstrated an extraordinarily close agreement between the phenomena noticed in the magnetization of actual iron and those presented by a model consisting of groups of little pivoted magnets Even the less conspicuous features of the actual process were reproduced in the model with a fidelity which went far to confirm this molecular theory of magnetism It was shown, for instance, that the model reproduces a phenomenon familiar in real iron, namely, the tendency which magnetic changes exhibit to be imperfectly cyclic, under cyclic changes of magnetic force, until these are repeated several times, and also that in the model, just as in real iron, this tendency disappears if a process of demagnetizing by reversals of gradually diminishing magnetic force has been previously gone through

The lecturer proceeded to show in action a novel apparatus he had devised to exhibit the magnetizing process in actual iron, and to test the magnetic qualities of metals This magnetic curve tracer (Fig 1) consists of two wires—AA and BB—tightly stretched in two narrow gaps in the magnets DD and C respectively The magnet C consists of a piece of slotted iron tube, which is kept constantly magnetized Consequently, when a variable current passes along the wire BB that wire sags out or in, giving azimuthal movement to a mirror F The variable current which passes through the wire B serves to magnetize the electromagnet DD, which consists of two bars of the iron to be tested, sunk into fixed pole pieces and united at the back end by a short yoke-piece of soft iron When the magnetism of DD varies it causes the wire AA, which carries a *constant* current, to sag up and down, and this gives movement in altitude to the mirror E The mirror is pivoted on a single needle point, and has freedom to respond to the motion of both the stretched wires AA and BB Since its azimuth movement is proportional to the magnetizing current, and its altitude movement is proportional to the magnetism acquired by DD, the mirror causes a spot of light reflected from it to trace out the ordinary magnetization curve, showing the relation of magnetism to magnetizing force By making the variable current change continuously from a positive to an equal negative value and back again, a complete cycle of magnetization was performed in the bars DD, and in this way the magnetic characteristics of the bars could be completely determined in a few seconds The lecturer proceeded to test in succession a pair of wrought-iron bars, then a pair of hard steel bars, and finally a pair of cast iron bars, causing the cyclic curve for each material to be automatically drawn on the screen, on a very large scale, to exhibit the features of difference The mirror and other moving parts of the apparatus were so dead beat that it was possible to go through a cycle ten or even twenty times a second without experiencing inconvenience from the effects of inertia. In that case, however, the iron must be laminated to avoid sluggishness in the magnetizing process itself Using an instrument with a magnet consisting of a split ring of iron wire, a process of periodic reversal was performed at a speed sufficient to make the curve traced out by the light spot become a continuously luminous line (Fig 2), and the process

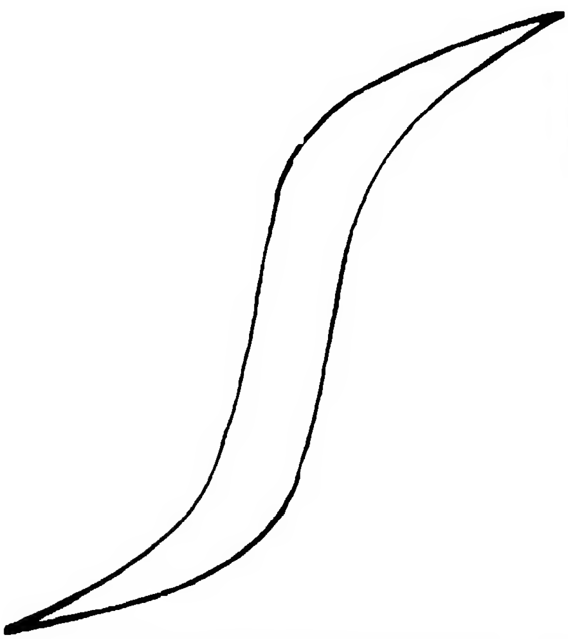

FIG 2—Photograph of Magnetization Curve traced by Prof Ewing's Magnetic Tester

of demagnetizing by reversals was illustrated by making this curve gradually contract itself to zero by slowly reducing the strength of the current while the rapid periodic reversals were continued. The effect was also shown of superposing one periodic alternation upon another, by which loops resembling those of Fig 3 were drawn The lecturer pointed out that these experiments went some way towards answering the question whether the magnetizing process went on in the same way, and involved the same dissipation of energy through hysteresis, at

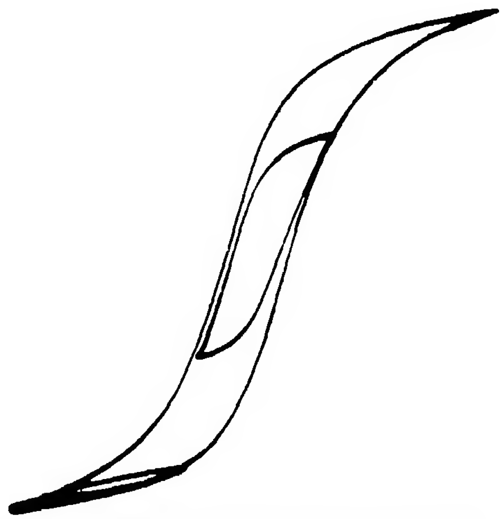

FIG 3 Photograph of Magnetization Curve with Loops

high speeds as at low speeds He concluded by expressing the hope that this apparatus would prove of some service to the builders of dynamos and transformers by giving them a novel means of testing the magnetic properties of their iron with great completeness and in a manner sufficiently simple for workshop use

BOTANICAL PAPERS AT THE BRITISH ASSOCIATION

IN our account of the proceedings of Section D of the British Association (NATURE, August 25, p 403), we promised to refer on a later occasion to some botanical papers which could not then be noticed The following are abstracts of several of the more important of these papers —

"Observations on Secondary Tissues in Monocotyledons," by Dr. Scott and Mr Brebner (1) The secondary tracheides in Dracæna and Yucca develop simply by the enormous growth in length of single cells, the nuclei remaining undivided, and not by cell fusion, as many authors suppose (2) The cambium in the roots of many species of Dracæna does not appear in the pericycle, but in the cortex outside the endodermis The secondary growth starts from the insertion of a rootlet, the cambium being pericyclic near, and cortical at a greater distance from, the rootlet (3) Description of secondary thickening in Iridaceæ

"On the Simplest Form of Moss," by Professor Goebel The author stated that previous researches had led him to the conclusion that mosses and ferns did not stand in direct genetic relationship with each other, but that they are descended from simple alga-like forms, in fact the mosses pass through a developmental stage so alga-like in appearance that it was formerly described as an algal genus *Protonema* If the sexual organs of the moss arose not on the stem but on the protonema, we should have the sexual generation agreeing perfectly with the filamentous algæ The leaves of the moss would then arise originally as protective organs for the antheridia and archegonia. This, up to the present, hypothetical form, actually occurs in Buxbaumia. In this moss the antheridia occur at the end of a protonema-branch, surrounded by a mussel-shaped envelope The female plant is more highly organised, but is still much simpler than in other mosses. These and other observations lead Prof. Goebel to the conclusion that Buxbaumia is a very ancient form which stands in the closest relation to the lower algæ.

"On the cause of Physiological Action at a Distance," by Prof L Errera (Brussels) The author referred to Elfving's observation, that sporangium bearing filaments of *Phycomyces nitens* are attracted by iron, zinc, aluminium, and various organic substances, such attractions not being due to gravitation, light, moisture or contact, but to physiological action at a distance, as Elfving terms it

The author has made numerous experiments which tend to show that the attraction is really hydrotropic, the filaments being attracted by hygroscopic and repelled by non hygroscopic substances, for example —

Any modification of iron which lessens its capacity of rusting at the same time diminishes its attraction on Phycomyces thus, polished steel scarcely attracts, and nickled steel does not do so at all

China clay, which is very hygroscopic, attracts energetically, while china exhibits no attraction These experiments succeed also in a saturated atmosphere, which shows that hydrotropism is not due, as generally supposed, to differences in the hygrometric state of the air

"Notes on the Morphology of the spore bearing members in the Vascular Cryptogams," by Prof F O Bower The author explained by the help of a large series of diagrams his views already laid before the Royal Society, as to the homology of the fertile frond of Ophioglossum with the sporangium of Lycopodium In support of the probability that the former may have been derived from some such type as the latter, by a process of partial sterilization of the sporogenous tissues, he adduced facts relating to Isoetes and Lepidodendron, both of which show a sterilization of parts of the potential sporogenous tissue in the form of trabeculæ in the sporangium

Mr C J Druery sent in a communication, which was read and remarked upon by Prof Bower It related to a new example of apospory found in a young fern seedling, of which the second frond bore upon its margin a number of prothalloid growths The occurrence of aposporous development at so early a stage in the development of the sporophyte had not hitherto been recorded

"On the arrangement of buds in Lemna Minor," by Miss Nina F Layard The object of a series of observations made on budding duckweeds, was to ascertain whether any fixed rule is followed, both in the arrangement and order of production of the buds

Prof F Schmitz read a paper on tubercles on the thallus of *Cystoclonium purpurascens* and other red seaweeds The tubercles are constantly inhabited by bacteria, and appear to arise in consequence of infection by these organisms

"Calamostachys Binneyana, Schimp," by T Hick The object of the paper is to revise and extend our knowledge of the structure of this fossil fruit in the light of a number of preparations which have not been previously described The central part of the axis, formerly described by Carruthers and Williamson as vascular, the author finds to be cellular, thus removing the chief ground for Williamson's reference of the spike to the Lycopodiaceæ Round the cellular pith there are (usually) three primary vascular bundles, which are reduced to the condition of those met with in *Equisetum*, and the young shoots of *Calamites*, *i e* to as many carinal canals with annular and spiral vessels adhering to the margin

As to the affinities, the conclusion arrived at is that the fruit is that of some form of *Calamites*—as Carruthers maintained long ago—and perhaps that of the type known as *Arthropitys*

"Myeloxylon from the Millstone Grit and Coal-Measures," by Mr A C Seward Specimens of Myeloxylon (Brong), [Stenzelia (Gopp), Myelopteris (Ren)] were described from a limestone of Millstone Grit age in North Lancashire, their minute structure being fairly well preserved, and showing collateral bundles, gum canals (?), and the hypodermal tissues characteristic of the genus A much more perfect example from the Binney collection was referred to, of coal-measure age, in which not only the xylem but also the phloem elements had been mineralised in an unusual state of perfection

It was pointed out that in the Binney specimen the position of the Protoxylem on the Phloem side of the bundles was clearly shown both in transverse and longitudinal sections The affinities of Myeloxylon with Cycads and Ferns were briefly discussed, and the conclusion arrived at that this extinct genus, although differing in certain particulars both from Cycads and Ferns, should be placed much nearer the former than the latter

SCIENTIFIC SERIALS

THE *American Meteorological Journal* for September contains the conclusion of "Objections to Faye's Theory of Cyclones," by W C Moore Only a few of the more essential characteristics of cyclonic storms have been considered, but from these the author concludes that it is evident that the generally accepted theory of convectional motion gives a more satisfactory explanation of the various phenomena than the theory advanced by M Faye —"Changes of Plane of the Mississippi River," by Prof T Russell The author analyses a report by Colonel C R Suter, of the Mississippi River Commission relating to the improvement of the river and methods of preventing overflow —"Thunderstorms in New England during the Year 1887," by R de C Ward The difficulty of predicting thunderstorms is shown by the fact that in New England in 1887 the majority of storms occurred in the south eastern quadrant of cyclones, while in the previous year the majority occurred in the southern or south-western quadrant Only 40 per cent of the summer thunderstorms of 1887 occurred in the southern part of cyclonic storms, while in the previous year the number was 70 per cent —"Weather Forecasting at the Signal Office, June 30, 1891," by Prof H A Hazen At this date the weather service was transferred to the Agricultural Department, and the author has given the results of his experience by laying down certain fundamental rules which would be of service to a beginner in the work, as it has sometimes been suggested that it would be almost impossible for a forecaster to impart his knowledge to another —"The Effect of Topography upon Thunderstorms," by R S Tarr The author's observations have led him to believe that topography has a decided effect upon the path of thunderstorms when they are beginning When, however, the storm has assumed more than local proportions, topography has in all probability very little effect upon its motion

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, Sept 26 —M Duchartre in the chair —On the white rainbow, by M Mascart A new mathematical treatment of the subject shows that the diameter of drops giving the most perfect achromatism is 29 17μ With drops of 30μ the rainbow will appear the whiter, the more the apparent diameter of the sun hides the excess of blue intermediate between the achromatised points, as well as all the supernumerary arcs, by the superposition of several systems of fringes, so that there is only left an exterior border slightly tinged with red The same will apply to drops slightly different in one sense or the other, but the achromatism persists longer if the diameter diminishes The observation of clouds and fogs has shown that the diameter of the drops varies from 6 to 100μ, the last beginning to fall as rain Thus the circumstances favouring the production of white rainbows are of very frequent occurrence —Places of origin or emergence of the great cholera epidemics, and particularly of the pandemic of 1846–49, by M J D Tholozan From Dr Arnott's communications to the Physico medical Society of Bombay, from the documents of the Medical Committee of Bengal, and from the testimony of Ferrier, who was travelling in Afghanistan at the time, it is evident that the cholera epidemic which invaded Europe and America in 1847, 1848, and 1849 originated in Bokhara, whence it spread to Afghanistan and India, as well as westward Bokhara, Samarkand, Balkh, and Kunduz were attacked at the end of the summer of 1844, Herat and Kabul in October, Jellalabad at the beginning, and Peshawur at the end of November In the following summer the epidemic proceeded steadily eastwards into the "endemic area," reaching Jhelum and Lahore in May, 1845, Meerut in August, and Delhi and Agra in October, at the same time passing down the Indus to Kurrachee, and westwards to Meshhed, whence it proceeded in 1846 to Asterabad, Teheran, Recht, and Baku A similar example of an eastward progress of cholera occurred in 1865, when the great epidemic of Mecca, after having invaded Mesopotamia and Transcaucasia, spread to Teheran, and took the easterly route by Khorassan The writer expresses his firm conviction that the points of emergence of the choleraic epidemics must be considered as their points of origin. The idea that the different pandemic manifestations of cholera which

have depopulated Europe must have invariably come direct from India is no longer tenable For Europe alone, two striking examples, in 1852 and 1869 respectively, have formally demolished the theories which regarded only things coming from the East as bearing any danger of contamination The epidemic of 1852 came from within Poland and Germany That of 1869 73 repeated the same things in Ukraine Nowadays, when these facts have taken their place in science, some minds seek to diminish their importance by pointing out that these epidemics revived some previous epidemics which had their origin in India But that which makes the spreading epidemic or the pandemic is the revival of the choleraic principle or germ with all its original attributes Even in India similar revivals perpetuate the annual endemic, and the epidemics which appear every three, four, or five years. This is the main fact which governs the entire history of cholera, and upon which micro biological research must proceed What difference of morphology, of virulence, or of reproductive faculty is there between the germs of the epidemics which die out at their origin, and those of the epidemics which revive several times, and can invade the whole world without proceeding from India?—Application of a conventional system of rectangular co ordinates to the triangulation of the coasts of Corsica, by M Hatt The trigonometrical network drawn for the hydrographic mapping of the coasts of Corsica describes a closed curve The employment of the conventional system, which transforms into rectangular plane co ordinates the polar co-ordinates reckoned on the sphere round an origin, offers numerous advantages The suppression of the sphericity permits the application of processes of calculation which have been dealt with in a preceding communication on rectangular co ordinates On this account it was interesting to test on a larger scale the methods which had only been utilised for the determination of secondary points The experiment has given satisfactory results, and exhibits the practical advantages of the new system of co ordinates and the methods of calculation K being the length of the geodetic line joining a point to the origin, and Z the angle made by this line with a fixed direction, the conventional co ordinates are $x = K \sin Z$ and $y = K \cos Z$ These assumptions permit the rapid and easy calculation of tables of corrections —On a new hydro carbon, suberene, by M W Markovnikoff —Action of piperidine and pyridine on the haloid salts of cadmium, by M Leopold Hugo

Sydney

Royal Society of New South Wales, June 1 —General Meeting —Prof Warren, President, in the chair —The following papers were read —Oceanic philology, by Sidney H Ray, a determination of the magnetic elements at the Physical Laboratory, University of Sydney, by S Coleridge Farr, on certain geometrical operations, by G Fleuri, analyses of the well, spring, mineral, and Artesian waters of New South Wales, and their probable value for irrigation and other purposes, by John C H Mingaye, remarks on the large sunspots visible at the present time, by H C Russell, F.R S

July 5 —Chemical and Geological Section —Prof Liversidge, F R.S, in the chair —The following papers were read —Microscopic structure of some intrusive rocks in the neighbourhood of Sydney, by Rev J Milne Curran, notes on the occurrence of platinum and its associated metals in the Richmond River sands, also in lode material in the Broken Hill district, by John C H Mingaye

July 6 —General meeting Prof Warren, President, in the chair —Paper read —On the ventilation of sewers and drains, by J M Smail

July 15 —Medical Section —Dr Fiaschi in the chair —Paper read —Recent work on the pathology of cancer, by Dr G. E Rennie

August 3 —General Meeting —Prof Warren, President, in the chair —The following papers were read —Flying machine work, and the 1/4 I H P steam motor weighing 3¼ lb, by L Hargrave. The paper described the experimental work carried out by the author during the past twelve months A compressed-air-driven flying-machine (No 16) had no less than twelve trials, on one of which it flew 343 feet, the speed being a little over ten miles per hour On the first trial it was fitted with a bi-plane, which was found to be a very stable form Some curious experiments with a segment of a hollow cylinder were recorded A description was given of a steam engine and boiler for a flying-machine, the total weight of which is 3¼ lb., including fuel and water the indicated horse power developed was 169 Nine detail drawings were shown, including those of an air pump and small-pressure indicator On the venom of the Australian black snake (*Pseudechis porphyriacus*), by C J Martin, Demonstrator of Physiology in the University of Sydney, and J McGarvie Smith

CONTENTS

THURSDAY, OCTOBER 13, 1892

VIVISECTION AT THE CHURCH CONGRESS.

THE attitude of the Church towards science at the present day shows a healthy spirit of tolerance It fully recognizes that research in physical science is the very embodiment of the seeking after truth, and that the proper exercise of faith is consonant with an attitude of expectancy This year, however, has seen an attempt, led by Bishop Barry, to disturb this harmony and to create an exception, namely, in the case of scientific research in Biology, whether of normal structure as physiology, or of abnormal, as pathology At the Church Congress last week the following was referred for open discussion at the instigation of Bishop Barry, who, however, wished, it is stated, to have had a much more sweeping theme presented —

"Do the interests of mankind require experiments on living animals, and, if so, up to what point are they justified?"

There was here presented to the Congress the twofold aspect of the question—utilitarian and moral—the obvious desire of the Subjects Committee being that they should thus have laid before them on these two points the evidence of the usefulness of scientific experiments on living tissues, and the evidence that such research is consonant with morality.

To all scientific men, even if not biologists, there is no need of evidence that experiments on living tissues are necessary to the progress of physiology and pathology As Mr. Horsley showed in his speech, this position is *a priori* established, since the processes of life are chemical and physical in nature, and can only therefore be advanced by experimental observation whether in the laboratory or by the bedside It seems, by the way, to have escaped the notice of all the speakers that every new clinical fact is as much the outcome of "experimental" observation as any note made in a laboratory We would lay stress on this since not only do some dignitaries in the Church but even a few medical men seem to think that clinical discoveries are the result of inspiration, and not the outcome of trying this or that modification of factors and noting the subsequent effects. However, if the Church Congress wanted facts they were supplied in overwhelming degree, and not only facts on the utilitarian side but also many—some unexpected to judge by the excitement produced—on the moral condition of anti-vivisectionists and their beliefs. Putting aside for a moment the utilitarian side of the question, it is doubtful whether the moral responsibility of anti-vivisectionists has ever been more freely exposed to view After Dr. Wilks had revealed the inconsistency of the agitators and their free use of animals (without anæsthetics) for their own ends, Mr. Horsley probed the consciences of the bishops by pointing out that "it has always been a matter of the utmost surprise to the medical profession that educated men in positions of the gravest moral responsibility like bishops should have in this matter descended to receive the information they require from sources of notoriously tainted character, rather than by seeing for themselves in our University laboratories what scientific experiments are in reality"

It is certainly a very fair question to ask of Bishops Barry and Moorhouse—What right had they to lend their help to any cause, however righteous it may appear to them, unless they have made a *bona-fide* effort to hear both sides? Has Bishop Barry visited the Physiological Laboratory at Oxford, or Bishop Moorhouse that and the Pathological Laboratory at Owens College? And if not, why not? Most especially ought such care to have been exercised in the case of anti-vivisectionism, since the leaders of that party have attacked not merely individuals, but the whole medical profession as "murderers," "torturers," &c, and have accused them of the grossest cruelty and self-seeking The bishops referred to have, it is to be feared, forgotten that their office is a very reverend one, not to be lightly used to help any and every alleged reform, and above all not to be used as a means of unfounded denunciation of what Mr Horsley truly calls an honourable, earnest, and hard-working profession

It is difficult to see on what possible ground Bishop Barry can defend his use of the expressions "arrogance," "physiological insolence," when he applies them, as he has done, to the simple statements of fact which have been formulated into the following resolutions, the first passed at the International Medical Congress of 1881, and the second at the recent meeting of the British Medical Association at Nottingham

(1) "That this Congress records its conviction that experiments on living animals have proved of the utmost service to medicine in the past and are indispensable to its future progress That accordingly, while strongly deprecating the infliction of unnecessary pain, it is of opinion, alike in the interests of man and of animals, that it is not desirable to restrict competent persons in the performance of such experiments"

(2) "That this general meeting of the British Medical Association records its opinion that the results of experiments on living animals have been of inestimable service to man and to the lower animals, and that the continuance and extension of such investigations is essential to the progress of knowledge, the relief of suffering, and the saving of life"

We are glad to see that these unanimous resolutions were read to the Church Congress and appreciated by the audience at their proper value and not according to the estimate of Bishop Barry. Similarly, men of science may not only ask whether Bishop Barry was a moment justified in speaking of physiological research as "cruelty" and "demoralization" while ignorant of the real facts, but they certainly have the right to demand that, should he fail to respond to the challenge offered him by Mr. Horsley, and substantiate his grounds for making these assertions, he should withdraw from the agitation (which has, we suspect, only injured his reputation), and make a free and ample apology.

In the same manner also we would call upon Canon Wilberforce to retreat from the unworthy position into which he has been thrown by the force of feeling uncon-

trolled by reason, and not to make the wrong he has done to science greater by continuing to persist in it regardless of the published demonstration of his error

One curious feature of the whole popular view of the anti-vivisectionist campaign is the general belief in the good faith of Miss Cobbe To men of science her methods have been familiar ever since the commencement of the agitation, and more especially since they were clearly displayed in the published trial of Adams v Coleridge By the general public, however, she was regarded as a fanatic, but trustworthy After this latter-day exposure at Folkestone to which she has been subjected we hope that such credulity has at last seen its end, for by the production of Miss Cobbe's latest book, "The Nine Circles," and by comparing it with the originals of the scientific papers from which her statements were alleged by her to be taken, Mr Horsley had no difficulty in convincing the Congress that her statements of facts can no longer be relied upon

It is an old story that a lie dies hard, but die it does at last, and the proceedings of the Church Congress have greatly accelerated the end

Nothing can do this better than for scientific investigators to patiently instruct the public At the Church Congress this heavy task fell on Dr Ruffer, who by way of answer to the vague rhetoric of the Bishops, piled fact upon actual fact until his audience showed how they welcomed the statements of truth as a counterpoise to Episcopal excommunication

The painful position of medical men who can be found willing to sanction such an agitation was well exhibited by the action of Mr Lawson Tait, who having publicly charged Church Congress officials with excluding him from the meeting, was positively proved to have withdrawn himself, the withdrawal being contained in his letter read to the Congress by the chairman of the Subjects Committee, the Bishop of Dover

Lastly, on the broad question of utility, no member of the Church would, we are sure, feel justified in contravening the view that the general regard shared by all Englishmen, and expressed in the above-mentioned resolution of the International Medical Congress, for the proper, that is, humane, use of animals, is ample surety that whether for the sake of food or pursuit of knowledge, the object is obtained at a minimum cost of pain

The most extraordinary illogicality was displayed on this very point by Bishop Moorhouse, of Manchester, for while declaiming against the killing of animals to gain knowledge, he clamoured for liberty to destroy any number to preserve the volume of his voice

But if we were to speak of the illogicality of the anti-vivisectionists there would be no end, seeing that as they do not or will not learn the truth, they live in a circle of contradictions Suffice it to say, that we believe the open discussion of the subject at the Church Congress will do more than anything to show the public that the feeling exhibited by the anti-vivisectionists is one of unmitigated hostility to science, and not one of genuine anxiety for the humane treatment of animals devoted to the service of man

THE NEW VOLUME OF WEISMANN

Essays on Heredity By Dr A Weismann Authorized Translation Vol II Edited by E B Poulton, F.R.S, and A E Shipley (Oxford Clarendon Press, 1892)

IN this second volume of the new edition of Dr Weismann's essays there are brought together four essays which did not appear in the first edition, they are in a convenient form, well translated, and well printed

Nothing is more curious than the public appreciation of Weismann's essays, for in them is no trim, nicely balanced, carefully elaborated statement of his biological theories The successive essays appear as they were published You have the theories in their making, stretching from essay to essay, alive, contradictory, disjointed This historical method of publication is a thing to delight the student of biology, but, one had thought, a torture to the precisian and caviare to the general, yet the public continue to buy, discuss, and no doubt read his works

In "Retrogressive Development in Nature," Dr Weismann describes cases of vestigial organs or rudimentary functions To explain the occurrence of these, the transmission and accumulation of degenerate characters produced by disuse is unnecessary In every organ, as in every animal, variations occur, in every generation unsuitable variations are weeded out, and so the organ or the animal remains adjusted to its environment, or becomes more perfectly adapted to it But when a change of habit or of environment occurs, as when an eyed animal takes to living in dark caves, or when an animal that has been saving its life by swiftness comes into a region devoid of enemies, the less far-seeing or the less swift are not more quickly killed than their better endowed neighbours So far as sight or swiftness are concerned, a condition of panmixia occurs, and the organs of sight and flight slowly degenerate

The argument in "Thoughts on the Musical Sense in Animals and Men" is subtle, ingenious, and less familiar In insects and birds males are the musicians, and sexual selection is a sufficient explanation, but it is not so in man However, in the mammalia the organ of hearing is remarkably developed In the auditory organ of a rabbit there are structural arrangements for nearly two thousand note sensations, while a concert grand piano contains only eighty-seven different notes For the needs of life, the thousand gradations of sound in the woods and the field, of the hunter and the hunted, the mammalian organ is adapted Music itself is an invention, and from the rude melodies of primitive man to the art of Beethoven and Chopin, it has been progressively developed as the intellectual faculties have been developed

The third essay, "Remarks on certain Problems of the Day," is specially valuable, as in answer to certain criticisms by Prof Vines[1] many doubtful points are explained Specially to be noted is the clear re-statement of Weismann's contention that the nuclear substance is the sole bearer of hereditary tendencies, and the new evidence for it contained in the researches of Boveri and O. Hertwig Equally noteworthy is the admission, in

[1] NATURE, October 24, 1889.

reply to Prof Vines' citation of the parthenogenetic fungi, that not only sexual forms may vary into new species

It is to the last essay, that on "Amphimixis, or the essential Meaning of Conjugation and Sexual Reproduction," that most attention will be directed Here there is a full statement, with important additions and alterations of the central part of Dr Weismann's theories However they may bulk in public imagining, questions of acquired characters, of retrogressive metamorphosis, and so forth, are side issues of a search for the morphological expression of the processes of variation

Originally Weismann explained the two successive divisions of the nucleus of an unfertilized egg which form the two polar bodies as, in the case of the first an extrusion of that nuclear plasm which, having served to guide the maturation of the egg, became useless when the egg was mature, and in the case of the second, as a halving of the nuclear substance to make way for the incoming sperm-plasm

In parthenogenetic ova, one division and only one was predicted and found It was suggested that parallel processes occur in spermatogenesis

Subsequent research by O Hertwig and others has brought to light these parallel processes, and Weismann, seeking for a sign, got rather more than he anticipated For the processes in spermatogenesis show first a doubling of the germ-plasma, and then two successive reducing divisions, and it has been shown that exactly this happens in ova also Accordingly, Weismann rejects his original explanation of the first polar body as an extrusion of ovo-genetic nucleoplasm, and the new problem comes to be, what is the cause of that doubling of the nucleoplasm which in primitive sperm and germ cells precedes the two reducing divisions?

Weismann supposes that the ancestral plasms or units of heredity, to which he gives the name "ids," are arranged in "idants," or nuclear rods The doubling process takes place normally by longitudinal division, and simply doubles the number of idants without altering the arrangement of "ids" By this method the number of possible combinations is increased without alteration of the ids The process is a mechanical one to increase the chances of combinations when the idants of sperm and germ cells meet If the idants were coloured rods, to be arranged in pairs—say black, white, red, and yellow for four sperm idants, and orange, green, blue, and crimson for those of the egg-cell—obviously only four pairs are possible The black would have to unite with one of the four others But if before the arrangement in pairs each rod were split in two, there could be two combinations for black, and so on for the others No doubt in many cases the number of idants is far greater than four, and the mechanical arrangement for variations correspondingly greater From the large number of possible combinations there come the relative few individuals of the next generation, and there is thus a basis for the lawless and apparently capricious appearance of varieties Next in importance comes Dr Weismann's belief, based on theoretical considerations, and supported by experiments on *Cypris*, conducted for seven years, that in parthenogenetic reproduction heritable variations may occur But they are far less frequent than in sexual reproduction. But the whole of this essay is full of intricate and curious speculation, speculation which will have to come before every student of biology, and which, whether much or little of it becomes incorporated in the body of accepted knowledge, will at least play a large part in guiding and stimulating present research P C M

ELEMENTARY CHEMISTRY

The Standard Course of Elementary Chemistry By E J Cox, F C S Pp 344 (London Edward Arnold.)

THIS book consists of five parts, which may be obtained separately or bound up in one volume It is based upon the syllabus prescribed by the Education Department for teaching chemistry as a class or specific subject, and professes to lead the beginner from the "familiar" to the "less known" by means of "investigation," the teaching thus afforded being regarded as a branch of mental education as well as of useful knowledge The five parts deal respectively with the properties of the common gases, the atmosphere, water, carbon and non-metallic elements, and with metallic bodies, combination, symbols and formulæ

The general plan of the book and the manner in which the subject is approached have a good deal to recommend them, the detailed treatment contains, however, much which could be improved, and unfortunately much which the learner will have to forget as he progresses in the study of his science In the opening chapter, evidently for the sake of simplicity, the author uses the term heat in place of temperature More confusion on the subject of heat is made later on by the use of equations, such as

"*Chalk* and *Heat* } yield { *Lime* and *Carbonic Acid Gas*"

which appears to attribute to heat a material existence, and even more unsatisfactory are bald statements to the effect that "no heat is produced in the formation of a mixture Heat is produced in the formation of a chemical compound"

Considerable space is occupied in the comparison of the affinities of the elements Because certain metallic oxides, including iron-oxide, are reduced when heated in a stream of hydrogen, the affinities of the metals for oxygen are said to be weaker than that of hydrogen for oxygen In the case of iron and steam the author has to note that the inverse change—the oxidation of the metal by steam—readily occurs, and that the former statement as to the affinities of iron and hydrogen for oxygen, is apparently contradicted This contradiction might have indicated the futility of attempting to compare affinities in a general way and not with reference to the special conditions under which the experiments were performed The inverse change in the case of iron is said to occur when the "temperature" is favourable, but in reality the active masses of the reacting materials determine the direction of the change

Inaccurate statements are numerous Hydrogen is said to form "one-third part of water by volume," "a formula" is stated to "represent a molecule," and a base is given as "a compound of a metal with hydrogen and

oxygen" More objectionable still are occasional instances of bogus reasoning, the most striking example being an erroneous proof of the conservation of mass On three different occasions the indestructibility of matter is stated to be a consequence of the law of definite proportions Almost equally bewildering is an attempt to show that "a molecule occupies two volumes," an attempt which even when correctly carried out might well be excluded from a book which professes to discourage anything akin to cramming No advance is made in familiarizing the learner with accurate conceptions of atom and molecule, indeed the need for the latter conception in chemical philosophy is quite overlooked

Throughout the book the author's mode of expressing himself is frequently not the happiest To say that "air allows all bodies that will to take fire in it," or that "chlorine does not combine with an excess of hydrogen" is harmless enough perhaps On the other hand to talk of the "properties of a mixture" being the "sum of the properties of its constituents," or of the gas being kept dissolved in a bottle of soda water "by the pressure of the cork," or to say that "water has weight and exerts pressure" cannot but be puzzling to the intelligent reader

To prepare a thoroughly good introduction, of the most elementary kind, to the study of chemistry, is a work of considerable difficulty, indeed it is one which few of our leading chemists seem desirous of undertaking Enough we think has been quoted from the book under notice to show that the author has by far underrated the difficulty of this task

LIFE AND DEATH

Essai sur la Vie et la Mort Par Armand Sabatier (Paris Babé et Cie)

PROF SABATIER'S "Essai sur la Vie et la Mort" forms the fourth volume of the "Bibliothèque Évolutioniste," a series of books published under the direction of M de Varigny, with the view of expounding in a strictly scientific manner the different principles and the diverse applications of the theory of Evolution The series most appropriately begins with a translation of Wallace's "Darwinism," and it is gratifying to our national pride to find that the two other works which have as yet appeared in the series, Ball's "Treatise on Use and Disuse," and Geddes' and Thomson's "Evolution of Sex," as well as the two others announced as in the press, are all by British authors

The present essay, which extends over 280 pp, is the outcome of a series of lectures delivered at the University of Montpellier It is written in a clear, simple style, devoid for the most part of all technicalities which appeal only to the specialist The problems of life and death are dealt with from an exclusively biological point of view, and questions of morality and theology are hardly touched upon It is difficult to do justice to the views expounded in the book in the short space at our disposal, but an attempt may be made to give a short account of its contents. The first part deals with life the properties of living matter are considered in great detail, and Prof Sabatier endeavours to show that the attributes of life are found to some extent, at any rate, in dead matter According to his views "la matière brute est vivante aussi," but the manifestations are slow and dull To the Professor's mind living matter and dead matter are not absolutely distinct between the two states of matter there is only a difference of degree and not of kind "La vie donc est partout, dans la matière dite inanimée comme dans la matière vivante" The various features in which dead matter behaves like living, are considered at great length, but, curiously enough, no mention is made of Butschli's remarkable experiments on artificial amœbæ, recently described in the "Quarterly Journal of Microscopical Science."

This view being accepted, death in the ordinary sense of the word, naturally cannot exist, and the phenomenon which we usually call death becomes but another form of life—"la vie intense" simply passes into the state of "la vie lente" Immortality, according to our author, consists in the indefinite continuity of life ("la vie intense") without arrest or interruption. Like Weismann, he maintains that the negation or the contrary of such immortality involves the presence of a dead body or corpse. Weismann holds that ciliated infusoria are immortal if kept under favourable conditions, these conditions, of course, including frequent opportunities of conjugating Sabatier considers that such infusoria are only potentially immortal, and that the act of conjugation converts this potentiality into a real immortality In his opinion the primitive protoplasm was immortal, and the habit of dying has been acquired by the higher organisms in response to two stimuli, one internal and one outside themselves The internal cause of death is associated with a tendency innate in the living being to improve its position in the world, in response to which it has become more specialized, and developed new organs and powers This specialization has borne with it the seeds of death The external cause is the surrounding world, which constantly stimulates and promotes the organism to new efforts, and in the struggle for the mastery death is brought about

Although we fail to see that Prof Sabatier has thrown any new light upon the problems he attempts to solve, and although the explanations he advances seem to us inadequate, his book is a useful one, inasmuch as he gives us a careful summary of the numerous views advanced by various writers in the last twenty-five years, on the subject of life and death, and criticises with considerable ability the theories of Weismann, Goette, Minot, &c In fact, his destructive powers seem greater than his constructive.

A. E. S.

OUR BOOK SHELF.

Contagious Foot Rot in Sheep By Prof G. T. Brown, C B, 16 pp, 8 illustrations, (John Murray)

THIS pamphlet is a reprint from the second part of the current volume of the Royal Agricultural Society's Journal A few additional remarks on the prevention of foot rot have been added, and if the instructions given were fully carried out, the disease would soon cease to be troublesome The preventive suggestions are (1) separation from the rest of the flock for one month of all animals newly purchased, and (2) isolation of all animals affected.

In discussing the treatment of the disease, Prof. Brown

insists upon the importance of detecting it at an early stage, and in the first part of the pamphlet he explains how to do this with certainty

The pamphlet ought to be read by everyone interested in agriculture and to make it better known the Society has printed as a leaflet a few notes upon the subject. In America the pamphlet would be sent broadcast amongst those interested, and it is to be hoped that Government assistance may soon enable our own Agricultural Society to disseminate knowledge in a similar way

W T

How to Make Common Things By John A Bower (Society for Promoting Christian Knowledge, 1892)

It would be a strange boy who never wanted "to make something" The present little book has been prepared for boys who feel this desire very strongly, but do not quite know how to set about the fulfilment of their wish They will here find ample information on the best way of making a vast number of things, from a hat-rail to a galvanometer, from a pair of stilts to a needle telegraph The author assumes throughout that those whom he addresses are not being taught by a personal instructor in handicrafts, and that they are not the possessors of an elaborate array of tools His directions are clear and practical, and cannot fail to be appreciated by boys who find much to interest them in the exercise of ingenuity and manual skill

The Student's Manual of Deductive Logic, Theory and Practice By K R Bose, (Calcutta S K Lahari and Co, 1892)

THIS book is intended for the use of students at the various Indian colleges, and will be regarded by most teachers of the subject as, upon the whole, a very good text-book The author has read many of the best European writers on logic, and presents clearly a summary of their results He begins with a definition of logic, gives some account of its "branches and parts," and then considers terms, propositions, and inferences What he himself describes as "the distinguishing feature" of the book is a collection of problems and exercises with solutions, or hints towards solution, in close correspondence with the subject-matter of the text

A Text-Book of Agricultural Entomology By Eleanor A Ormerod Second Edition (London Simpkin, Marshall and Co 1892)

THE first edition of this book was published about eight years ago It consisted of lectures which the author had delivered at the Institute of Agriculture of South Kensington There was not much demand for it until last year, when attention was directed to it by the arrangements of the County Councils for the promotion of agricultural education The work was then so widely appreciated that a new edition was soon called for, and there can be no doubt that in its new form it will be more popular than ever, for Miss Ormerod has done everything in her power to make it not only scientifically accurate but practically useful. Students will find it of great service in helping them to a knowledge of insect life and of the best remedies for "infestations"

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications.]*

A Functional Hermaphrodite Ascidian.

As of late years a considerable number of structural hermaphrodites have been shown to be protogynous or protandrous, or to have some special modification for the purpose of preventing self-fertilization, it may be of interest to have on record a case of a completely functional hermaphrodite

I had living lately in one of my dishes a large *Ascidia* (probably *A rubicunda* of Hancock) which I observed one morning to be expelling eggs from the atrial aperture The eggs were emitted in batches of from about twelve to twenty at a time, and immediately after each set of eggs came a little white milky jet which hung like a string in the water for a few seconds and then spread out and disappeared On catching some of this string in a pipette and examining it with the microscope it was seen to be a mass of active spermatozoa This alternating passage of ova and spermatozoa continued for fully an hour

The ova at first floated at the surface of the water for a short time and then slowly sank to the bottom On examining some of those on the bottom of the dish after a couple of hours they were found to have commenced development, being in various stages of segmentation so there can be no doubt that self-fertilization had taken place

Very likely this occurs in some other species also, but another common Ascidian (*Corella parallelogramma*), of which I had had several large specimens living a few weeks before, laid eggs in my dishes, and I could not detect any spermatozoa being produced by these individuals. They were functionally female although structurally hermaphrodite

The Present Comets

ON the 27th ult about 15½h G M T comet Brooks (c, 1892) had a tail 10' long, pointing at a position-angle of 280°

At the latter part of last month Swift's comet (a, 1892) was still a very conspicuous object in a 4¼ inch refractor Observations on several nights showed that it not only still had a very faint tail—at position angle 260 on the 24th at 8½h, when I observed it to be certainly 11' long, and suspected it to 21'—but that also there was an elongation nearly in the opposite direction, while I believe the radius of the head was less towards *n* than towards *s*, but I have not been able to satisfy myself of this

Sunderland, October 5 T W BACKHOUSE

Women and Musical Instruments

IN looking over a very large collection of musical instruments from the aborigines of America, I am surprised to find that there is not one peculiar to women, and that those of the men are never played by the women It is true that the females beat time on various objects and may now and then use the rattle This disappointing fact arrested my attention, and I am curious to know whether savage women, or any other women for that matter, have ever invented a musical instrument, and whether in savagery they even play upon those invented by the men The composition and singing of songs might also be inquired into, though our American savage women do join in certain choruses OTIS T MASON

Determination of *g* by Means of a Tuning Fork

MR C V BOYS informs me that for the converse process of determining the pitch of a tuning fork, the experiment I described recently is no new one, but has been used by him for the last ten years in the instruction of students in South Kensington I observe, however, that he has not made the same use of the trace to eliminate the zero error A. M WORTHINGTON

THE TOTAL ECLIPSE OF THE SUN, 1893

AS I have been asked by some astronomers to give a description of the general appearance and climate of this part of Chile, in which a total eclipse of the sun occurs next year, I have drawn up for publication the following account —

The eclipse takes place on April 16, 1893, at about 8 15 A.M., Chile local time, and will be seen to the greatest advantage in this part of the Province of Atacama.

At the sea coast the central line of total eclipse passes close to Chañaral 29° S L This is not the better known Chañaral, north of Caldera, but a small place equidistant from Coquimbo and Carrizal Bajo The southern limit of total eclipse is 29° 50' S L just north of Coquimbo, and the northern limit 28° 10', just south of Carrizal Bajo

The band of total phase stretches between these two limits in a north-easterly direction, across the country, from the coast towards the rising sun Along the central line of this band the sun will be hidden by the moon for nearly three minutes The eclipse will be total everywhere within the limits given above, but the total phase will be shorter and shorter the nearer those limits are approached, and outside of them the eclipse will be partial

On the accompanying map of the Carrizal and Cerro Blanco and Copiapo Railway systems I have marked the northern and southern limits, and the central line of totality

It will be seen that the port of Carrizal Bajo, 28 4' S L, is just outside the total band, but the railway connecting it with Yerba Buena intersects the central line of total eclipse 70 miles inland, and a branch to Merceditas, 60 miles inland, at an altitude sufficiently high to be above the damp and hazy atmosphere of the coast At the points of intersection the climate is simply perfect for astronomical observations, and is also, during the month of April, delightful to live in

The accompanying form was filled up, in compliance with a request from Amherst College Observatory, to show the cloud conditions in the inland region during the month of April this year as an indication of what might be expected during the same month next year

Cloud Observations at "Mina Bronces," Chile, 1892

Day	Local time 7 45 a m	8 15 a m	8 45 a m	Remarks
April 10	2	2	2	Clouds were light, allowing a slight shadow to the east Bright sun at intervals
,, 11	2	0	0	Clouds were on the horizon, so that the sun rose above them at 8 o'clock
,, 12	0	0	0	Perfectly clear sky
,, 13	0	0	0	Perfectly clear sky Sun rose at 6 22 a m
,, 14	0	0	0	Sun rose at 6 22 a m

,, 26	0	0	0	
,, 27	4	3	3	Haze thick at 8 15 a m, but light at 8 45 a m
,, 28	0	0	0	Sky got cloudy at midday
,, 29	0	0	0	
,, 30	0	0	0	

KEY

0 = "Sun entirely clear from clouds "
1 = "Clouds generally scattered "
2 = "Clouds massed about the sun "
3 = "Sun in haze or fog "
4 = "Sun invisible in thick clouds "

I had two series of observations made, one at Mina Bronces by Mr Martin, chemist to the works (the results of which are hereto appended), the other at Cerro Blanco by Senor Miranda, at his mine Both reports are in every respect alike The 10th and 27th were cloudy, all the other days absolutely clear As the two stations are some twenty five miles apart, these reports show that there is no local weather, and that it is only when a general atmospheric disturbance, originating in the Cordillera de los Andes, occurs that the weather is affected at these high stations

It will be seen that there was only one day—the 27th—out of twenty-one days of observation on which the sun was not visible at eight o'clock in the morning, for on the other cloudy day—the 10th—the sun was bright at intervals

Observatory Stations

I have marked on the map, along the central line of totality, several stations that I think suitable for observatories, the positions are only approximately correct, for I have no means of determining them accurately, but the errors, if any, cannot be great

Undernoted are heights above sea level of some places shown on the map —

Yerba Buena railway terminus	3867 feet
Cerro Blanco, north hill	10,000 ,,
,, south, Peineta	8000 ,,
Carrizo, in the valley, a small farm	5000 ,,
Merceditas railway station	2900 ,,
Cerro del Jote	6000 ,,
Cerro del Cobre	8000 ,,
Lay observatory	4000 ,,

Cerro de Peineta is part of Cerro Blanco, this Cerro Blanco is not part of the Andes, but a detached hill with low ground all round, and a clear view to the north-east It is easily ascended by pack-mules

Carrizo is not a hill, but a small farm or large garden, irrigated by a mountain stream The advantages of this station are nearness to the railway, a good road, and plenty of small hills of easy ascent to select from

Cerro del Cobre is a good hill, but probably too far south However, there are hills all the way from Merceditas that might be selected (see Mr Martin's letter)

Serra del Jote, near Merceditas, is accessible to pack-mules half-way up, higher than which it would not be necessary to go Moreover, it is said that the rest of the ascent is difficult The three hills, Cerro de Peineta, Cerro del Cobre, and Cerro del Jote, can all be seen from one another

Lay Observatory On April 15 I went to Merceditas and stayed overnight, as I wished to find near the railway station a hill on which the sun shone at an early hour on the morning of the 16th, through some opening among the surrounding hills, and which would be suitable for ordinary lay observers who had no expensive apparatus, but who wished to see the eclipse well through a smoked or coloured glass To the south of the railway station I found a range of hills eminently suited to the purpose; at a height of 4000 feet above the sea the sun shone over a dent in the Jote at 6 40 a.m The hill is much higher than 4000 feet, but I did not go higher This is an excellent, well-sheltered spot, and would do well as a station for professional astronomers. I went up on horseback in forty minutes, but the ascent, from the railway station, could be easily made on foot in an hour As I could not find any local name for this hill, I called it the Lay Observatory

Climate—At two o'clock in the afternoon of April 15

the temperature at Merceditas was 78° F, this was the hottest time of the day, and it was a warmer day than usual, and at 8 p.m. the temperature was 62° F. Next morning, the 16th, I got up at two o'clock to see the comet then visible, and found the temperature was 58°, at 5 a.m. it was 56°.

Everywhere on the coast of Chile, north of Coquimbo, the sun, in the morning, is almost always obscured by a thick haze which makes the sky of a dull lead colour. This haze is sometimes driven away by the sun during the forenoon, but just as often it remains all day, especially during the months of March, April, and May.

This hazy morning atmosphere extends inland for a distance of about 40 miles and up to an elevation above the sea of about 2500 feet; beyond this distance and height the sky is almost always clear and the air dry. Standing, in the early morning, on a mountain of 3000 to 4000 feet, or higher, you look down on a great white sea of mist covered with whiter ridges like motionless waves, and studded here and there with islands, which are the mountain tops piercing through. This haze is usually gone by nine o'clock, except within about five miles of the sea.

Accommodation on the Hills.—Tents can be quickly and cheaply made with "esteros de totora," that is mats made of reeds. All the more temporary houses of miners and prospectors and of railway track repairers are made of these mats, which are seven feet square, and may be rolled up and carried from place to place. They form an article of commerce, and cost eighteen-pence each, or from eighty to ninety cents of Chile paper currency. During all the month of April and part of May it is quite safe to trust to this kind of tent, but not later than the middle of May, for rain or snow sometimes falls in the end of that month.

There are no venomous reptiles in Chile, nor are there mosquitoes on these hills, and fleas cannot live at an altitude of 4000 feet—no slight advantage.

Rain.—On the Chilian side of the Andes, in the province of Atacama, rain generally falls twice in the year: the first rain is expected in June, the next in July, each rain usually lasting two days, and always accompanied with wind from the north. As soon as the wind changes to its prevailing quarter, the south, there is beautifully clear but cold weather. From two to three inches of rain fall in the year, but sometimes less than one inch. On Cerro Blanco it usually freezes every night from July till the end of August, and some snow lies on the mountain till September. On the hillsides there are plenty of bushes and small trees for firewood, and excellent water is found in all the higher valleys.

I have heard one objection to this district for observing the eclipse, which is, that as the eclipse takes place in the morning, and the sun is not high in the sky, it would be better to go farther east. This objection has no weight, on account of the extreme dryness of the atmosphere. At the mines on Cerro Blanco and the other hills everything gets dried up; Huasco raisins grow hard and rattle on one's plate like nuts; agricultural produce, such as wheat, beans, and barley, brought from Southern Chile as food for man and beast at the mines, loses two per cent. of its weight every month for several months, office ink bottles have to be kept tightly corked or the ink very soon dries up, chairs and tables fall to pieces, veneer peels off, and a piano soon loses its tone. The sky is dark blue, and the sun rises white and dazzling without a trace of any other colour. The hills, the rocks, and the bushes cast dark shadows, and even every pebble the size of a hazel nut casts its shadow, so that in the early morning the gravelly ground seems half wetted with a shower; one side of every pebble is in bright light, the opposite in deep shadow.

Although the eclipse would be the object of greatest interest to visitors, a few weeks might be profitably spent among the copper mines, and if any one wished to become a mine owner, plenty of mines are to be had for the asking. All the mines belong to the State. You have only to take up a mine, pay a nominal licence to the Government annually, and the mine is yours as long as you pay the licence. There are no royalties, no surface rents, and no export duties. The next thing to do is to make the mine pay, and this is sometimes done.

There is no sport in April, but after snow falls on the Cordillera, huanacos and immense flights of turtle-doves come down to feed on the lower slopes. Life, however, is never wanting. The region from Cerro Blanco southward as far as Coquimbo is the home of the fur chinchilla. It feeds on the nut of the carbon tree, *Cordia decandra* (Hook. et Arn.), and on the pea of the algarrobillo, *Balsamocarpon brevifolium* (Clos). This bush, which produces the tannin pod of commerce, thrives best far inland, on sunny, almost rainless slopes, but it must have one shower in June or July, otherwise it bears no fruit. If there be no rain for three or four years—as sometimes happens—the bushes do not die—they just wait. The same thing happens with all the other bushes; sometimes, for several successive years, they are without leaves, and though the soil seems as dry as dust, whenever rain comes they show themselves full of life.

British astronomers—professional and amateur—ought not to lose the opportunity of observing under such favourable circumstances this great eclipse. I doubt if better conditions were ever offered before. The distance to come is long, but the expense is not very great, and can be exactly counted beforehand. An expedition might leave Liverpool in February, by Straits of Magellan steamer, and be home again in June. Or, after the eclipse, go by steamer to San Francisco or Vancouver, and thence by rail to the World's Fair at Chicago, and instead of encountering hardship and danger in some unhealthy climate, have a pleasant trip all the way.

Though horses and mules can be got here, every one should bring a saddle and bridle.

In conclusion I would impress on the members of every expedition that may come out, the importance of selecting, as observing stations, places at a distance of at least 60 or 70 miles from the sea. On the other hand, the advantages of going farther inland are doubtful, and as the railways go no farther, travelling would be more difficult.

JOHN KING,

British Vice-Consul, Carrizal Bajo, and Engineer of the Carrizal and Cerro Blanco Railway.

Carrizal Bajo, Province of Atacama, Chile,
May 1892.

(COPY OF MR. MARTIN'S LETTER.)

Mina Bronces, Jarilla, May 2, 1892.

DEAR SIR,—I have now the pleasure of enclosing the form which you sent to be filled up. As I did not receive your letter till April 9, I could not of course fill in the first nine days, but as you will see by the observations that as the last twenty days have been almost invariably clear, I think the astronomers could safely decide to come here as far as clearness of sky is concerned.

An observatory could very easily be placed on one of the spurs of the Cerro del Cobre, to the south of the latter. It is easily accessible to mules with 250 pounds and affords an uninterrupted view of the sunrise.

Hoping that the filling up of the form will be found to fulfil all requirements. I remain, dear sir,

Yours sincerely,
(Signed) WILLIAM M. MARTIN.

John King, Esq., Carrizal Bajo.

DR MODIGLIANI'S RECENT EXPLORATIONS IN CENTRAL SUMATRA AND ENGANO

LITTLE more than two years ago, writing in this journal on the results of Dr Elio Modigliani's accurate and highly interesting exploration of Nias (NATURE, vol xli p 587), I made the remark that our young traveller had shown that he was made of the stuff of the very best of scientific explorers It is therefore with no small pleasure and pardonable satisfaction that I now have the good fortune to show further proofs that I was not mistaken in thus judging him

Those who have once tasted the sweets of true exploration in little-known lands, and who are animated by the smallest spark of *fuoco sacro*, have felt and know well that thirst for further travels which goads the late traveller to new wanderings It was thus with my friend Modigliani, and he had hardly finished seeing his book on Nias through the press, when he began to long to be away again He first thought of taking off the edge of his peregrinatory desire with a visit and collecting tour to the less-known parts of our new "Eritrea," but an accident, which might have had serious consequences, kept him back on the eve of departure On regaining his health, far from being discouraged, he matured a wider and bolder plan—that of returning to the vast and lovely lands of the Malayans, and penetrating to the heart of Sumatra through the country of the Toba Battaks

Dr Modigliani left Florence in August 1890 Early in October he was at Siboga, then at Padang Sidempuan, in Sumatra, where he interviewed Mr van Hasselt, well known in connection with the big Midden Sumatra exploration ,' however, as the sequel proved, not much information and aid were got from Mr van Hasselt and his Government , besides, war was going on in the Toba region, but this did not deter Modigliani from his object He had secured the services of Abdul Kerim, the Persian collector and taxidermist, who had been with Marquis G Doria from 1862 to 1874, first in Persia, then in Borneo and Tunis, and finally at the Museo Civico at Genoa, which, under Doria's energetic and enlightened direction, has, during the last twenty-five years, been one of the most active and fertile centres of zoological research in the world This was fortunate, for the Javanese hunters and collectors engaged at Buitenzorg were not very efficient

Although he included in his baggage only things that were strictly necessary, he had to engage at Siboga forty-one carriers, mostly Toba Battaks, to convey it to the lake That route, hardly practicable twenty years ago, is now safe, and the only trouble met with was from Dutch convicts engaged in repairing the road It was on this road, at Ayer Kotti, that the American missionaries, Messrs Munson and Lyman, not many years ago, were killed and eaten by the Battaks of the neighbouring village, Huta Sakkak. The country rises continually from the coast until the highlands of the Toba plateau are reached , it is undulated with mountains and broad valleys, such as that of Silindung, but on the highlands the forests have disappeared, and the watered depressions with dense vegetation and the clumps of bamboos surrounding the villages are dotted about At Tarutung, the principal village of Silindung, Modigliani obtained important information on the independent Battaks from Mr Welsink, the Dutch Assistant-Resident, who had long resided in the Battak country, and been some time *Controleur* at Laguboti on Lake Toba, now occupied by the Dutch The Singa Manga Rajah, head chief and religious primate of the Battaks, who had already given so much trouble to the Dutch, was again coming to the front, and this time in connection with the irrepressible Atchinese from the north—an alliance of hereditary foes, for the Battaks have always repulsed the Mohammedan Malays against the invading whites

By the middle of October 1890, Modigliani was at Balige on the shore of Lake Toba, and on the edge of the wild and unexplored Battak country, the land of his dreams He describes the lake as grand and imposing, but more like a northern lake, such as Loch Lomond, because of its bleak bare mountains and early mists, than what might have been expected in the heart of a tropical island Lake Toba is about forty four geographical miles in length , a large mountainous peninsula divides it in two —Tao Silalahe on the north, and Tao Balige on the south At Balige Modigliani had the use of a good house, once occupied by Mr Welsink. He paid an early visit to the *Controleur*, Mr van Dijk, at Laguboti, who placed at his disposal the Government boat with its crew, but requested to be informed of any excursion on the lake beforehand, as some of the lacustrine villages were hostile Modigliani started for a first exploration of Lake Toba on October 27 An old chieftain, Ompu Rajah Doli, went with him, partly as guide, partly as protector He was on his *solu*, the long swift canoe, excavated from a single tree, with which the piratical enterprises on the lake are so deftly performed , this, not one of the largest, was 18 metres long and 1 metre in width , it was manned by eighteen paddlers and one steersman The place of honour is at the prow, which is singularly ornamented. At Ade Ade, one of the further villages, he secured the good will of the powerful chief, Ompu Rajah Hutsa, and with him visited

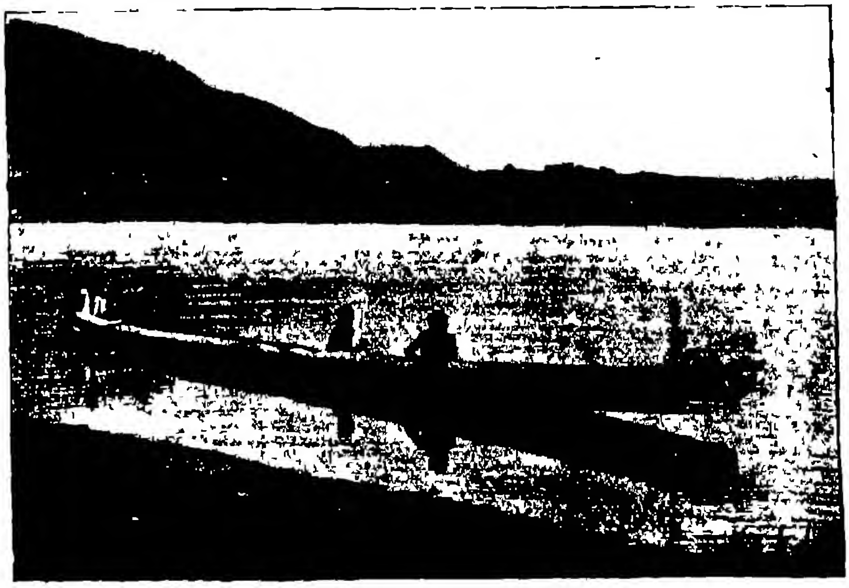

FIG 1—*Solu* (boat) on Lake Toba

the site of Lumban Rajah, the former residence of the Singa Manga Rajah, destroyed by the Dutch. The chiefs and head men of several neighbouring villages had assembled, and many were the questions they put to Modigliani. Amongst others, they asked him who was his Rajah. "The Rajah Roma" said he. This caused a great discussion, after which one of the chiefs said: "How is it that we, having sent to Rajah Rom (not Roma) presents of horses and buffaloes, have never received a return or an answer?" Modigliani was at first rather embarrassed at so direct a question, but replied that the presents had not been received, having perhaps been intercepted. This appeared to convince them, and a Rajah Uti was mentioned as apparently the guilty party. I have mentioned this episode because it turned out to be a most fortunate

Fig. 2.—The *guru* Samalain.

one for our traveller, who got to be known as the envoy of Rajah Rom, and even as that mystic personage himself. It appears that by that name a venerated authority is known to the Battaks, and Modigliani thinks it may be no less a personage than the Hindu god Rama. As the sequel will show, under the patronage of Rajah Rom, Modigliani was able to penetrate into the heart of the independent Battak country, where, in all probability, no other European would have been able to go; and many were the things he had to promise in Rajah Rom's name, and many the presents and great the aid he got as his envoy. The greatest depth found by Modigliani in Lake Toba was 450 metres; the temperature of the water was 24° to 23° C. at the surface, and 23° to 22° C. near the bottom. Only four species of fish, two of molluscs and two of crustaceans, appear to live in the lake.

As a locality better suited for zoological collections, Modigliani went in November to live in the forest of Si Rambe, where, at an elevation of about 1370 metres, he built himself a log hut. Here the maximum day temperature ranged from 28° to 30° C., the minimum night temperature from 12° to 13° C.

It was from his hermitage in Si Rambe that Modigliani, eluding the official impedimenta, started on his adventurous and bold journey across Sumatra, right through the country of the independent and hostile Battaks. Now his supposed connection with the legendary Rajah Rom did him a right good turn; for the yet more or less independent chiefs sought him out, hoping that through his influence Rajah Rom might be induced to redress their wrongs. Amongst these was a *guru*, one of their priests, wise men, and *literati*, named Samalain, a staunch friend of the Singa Manga Rajah, who not only visited Modigliani but undertook to guide and protect him in his exploration of the (by Europeans) untrodden Battak territory. In one of his letters to Marquis Doria, Modigliani gives a vivid description of the savage energy of *guru* Samalain, of his devotion to the Singa Manga Rajah, and of his love of independence. The *guru* sent seven of his devoted followers to act as carriers, and taking one of his Javanese hunters and his interpreter, Si-gu-tala, a Battak, Modigliani left his encampment in the forest of Si Rambe at midnight on December 19, 1890. The utmost caution was necessary to cross the frontier line without being discovered by the colonial authorities. After a forced march of ten hours, the *guru* having joined him on the way, Modigliani reached the village of Lumban Bulu, well within the territory of the independent Battaks. The village chiefs, with armed retainers, and those of some neighbouring villages, all fully armed and equipped, with spears, flint-lock muskets plated with silver and ornamented with ribbons, and their peculiar swords with heavy ivory handles, accompanied and surrounded him. His reception was far from friendly. They would not believe that he was not a Dutch emissary, and spoke of sending him back; even the energetic protestations of the *guru* Samalain were received with signs of doubt. At this juncture our traveller had a happy thought, and drawing from a pocket the flag of Italy, he suddenly displayed it, exclaiming: "This is the flag my Rajah gave me; see, it is different from that of the Dutch; but when it is unfurled Debata (God) is present—you must rise and uncover your heads." The difference was at once noted, and Puttua, the chief who had shown himself most hostile, turned to Modigliani and said, "*Tabi, rajahnami*" ("Hail, my chief"). The others joined, and then two fowls and a pipe were brought to our traveller, and orders given to prepare the *sirih* of welcome and friendship. This is done with special ingredients, the absence of any of which would do away with the sincerity of the offering.

Modigliani was thus allowed to enter the independent Battak country. The next day he resumed his journey towards the east coast. He had to pay for passing a bridge. The Battaks know well the value of money, and use the Spanish dollar divided into 480 *doits* of copper, bearing the date 1804, the British arms, and the inscription "Island of Sumatra" (or the same inscription in Arabic), or else simply a fowl.

Amongst the many interesting things he saw, heard, and learnt, special mention must be made of the magnificent waterfall formed by the emissary of Lake Toba. Modigliani had some difficulty in visiting it, for it is the reputed abode of powerful spirits, or *sombaon*. It is, he says, grand beyond description; all the rivers of the region join the emissary of the lake in the fall, the native name of which is Martua Sapuran Si-arimo: the result is the River Assahan, which flows into the Eastern Sea near Tangion Balei. This is an important geographical discovery, and our friend may well be proud of it. He succeeded in taking a magnificent photographic view of

the principal cascade Two Battak villages, Tanga and Suanan, are on each side of the fall Modigliani managed to visit both, though hostile to each other, as he learnt, on account of cannibal feats recently committed reciprocally, thus cannibalism is not yet extinct amongst the Battaks In this trip Modigliani went as far as Bandar Pulo, near the east coast, but not wishing to get into difficulties with the *Controleur* at Tangiong Balei, he turned back towards Toba, taking this time a new route up the valley of the Qualu or Kuwalu River

The return journey was adventurous, and more than once Modigliani and his small party were in imminent danger A war expedition of the Dutch had recently been this way, and the depredations and looting of the so-called friendly chiefs and their followers had left behind visible traces, and a burning sense of hate and vengeance against the *sordado* of the Cumponi (Dutch), although nothing can be said against the conduct of the Dutch colonial troops It required all the energetic persuasions of *guru* Samalain and all the calm courage of Modigliani to avoid hostilities At the village of Si Buttua, well fortified and in a commanding position, as most are, admittance was gained with difficulty, and matters went worse at the village of Lumban Ballic, where, however, finally Modigliani, as Rajah Rom, was treated with high honours and a dance His last station was at Hite Tano, the native village of his man Si-gu-tala Here, after some delay and hesitation, he was treated with friendliness, and to celebrate the return of Si gu-tala a buffalo was killed, a very grand feast in the Battak country A good tramp of fourteen hours took Modigliani from Hite Tano back to his log hut in the forest of Si Rambe He had been away a little more than a month

Of course, this adventurous trip of Modigliani amongst the independent Battaks got known, the Dutch authorities informed him that he would be expelled if he attempted again to cross into the Battak country, and he found that all his movements were watched and reported by the native police (*opas*) He therefore decided to return to Siboga, where he was on March 14, 1891 He remained there collecting and taking notes until the first days of April, when he proceeded to Bencoolen

The Geographical Society of Batavia had invited him to explore the island of Engano, and a Government steamer was to convey him there Modigliani had accepted with delight; but, after waiting some time in vain at Bencoolen for the promised steamer, he decided to start on his own account, and did so, engaging the *prahu* of a Chinaman.

Engano, the furthermost of the interesting islands which guard the western coast of Sumatra, has up to the present date been all but a *terra incognita*. Crawfurd, in his admirable "Dictionary of the Indian Archipelago," gives scant and partly erroneous information on Engano; whilst Vivien de St. Martin, generally so accurate, in his great "Geographical Dictionary," now being issued, says very little, and tells us that the natives are Negritos! And yet Rosenberg visited and explored the island not many years ago Modigliani, during his stay of over two months, made a thorough exploration of Engano, and of the ways and customs of its natives, and it is indeed fortunate that he went there and gathered such rich ethnological and anthropological materials, for the natives of Engano are rapidly dying out, like those of other savage islands Ten years ago they were about 8000, now, by the last reckoning of the Dutch Agent, they are reduced to 840!

The natives of this island certainly belong to the great

FIG 3—Battak chief and his wife

Malayan family On looking over the photographic portraits taken by Dr Modigliani, I was forcibly reminded of the Nicobarese, and Modigliani agreed with me on examining the fine series of photographs of natives of the Nicobar Islands in my collection, which I owe to the kindness of my friend, Mr E H Man, Deputy Commissioner of the Andaman and Nicobar Islands, and well known for his exhaustive anthropological researches in those two interesting groups.

Modigliani remained in Engano from April 25 to July 13, 1891 His health, which had hitherto resisted many

and various sore trials, was at last injured by the pestilential miasmatic emanations of the mangrove swamps of Engano, and he came away just in time to save his life At the end of July he embarked at Batavia, and by the end of August we had the pleasure of welcoming him back to Florence

He has already given brief accounts of his exploration of the Toba country in letters and in two lectures recently delivered at Rome and Florence He is now busy working out his ethnological materials, those pertaining to zoology have already been partly examined by specialists The principal novelties in zoology are, as was to be expected, from Engano Amongst those already published I recall the following —Birds *Graucalus enganensis*, *Pericrocotus modiglianii*, *Zosterops incerta*, *Geocichla leucolæma*, *Calornis enganensis*, *Gracula enganensis*, *Carpophaga œnothorax*, and *Macropygia cinnamomea*, are new species from Engano, recently described by Count Salvadori, besides, Modigliani has established the hitherto unknown habitat of a lovely Parroquet (*Palæornis modesta*) Reptiles *Draco modiglianii*, *Lycosoma relictum*, and *Coluber enganensis* are new species recently described by Dr Vinciguerra, also from Engano

On the anthropological and ethnological materials collected by Dr Modigliani on this voyage, which are many and of great interest, I intend writing a special report, which will be published elsewhere I will therefore, in concluding this communication, merely draw attention to their scientific value, mentioning the more important series

Amongst the Toba Battaks, Modigliani was not successful in obtaining human skulls, but, with the help of *guru* Samalain, he was able to take with rare ability and perfection a magnificent series of plaster masks of the face from life, both of men and women He has made, besides, a splendid collection of photographs illustrating the people and their habits A most extensive and perfect series of actual specimens and carefully constructed models made on the spot illustrate completely the houses, *sopos*, and boats, with their ornaments, the agricultural implements, house furniture, dress and personal ornaments, food and stimulants, with the utensils pertaining thereto, work-tools, and weapons offensive and defensive, religion and superstitions, witchcraft and literature The carvings on the houses, and the patterns of the textile fabrics of the Toba Battaks, are indeed remarkable as specimens of the finest style of ornamentation Amongst the numerous series illustrating the crude religion and manifold superstitions of this singular people, I may mention the carved wooden figures, with movable arms and a square hole in the chest, in which is the sacred relic (*pangulubalang*) or talisman containing part of the remains of a sacrificed child, these figures, of which Modigliani has collected quite a number, are as rudely made as the *karwars* of North-west New Guinea Of the remarkable magic staffs, called generically *tungal pagñaluan*, but which appear to have individual names, Modigliani has secured seven, they consist of superposed figures, more or less conventionalized, but beautifully carved in a hard dark wood in most cases, in which the human figure and those of the elephant, buffalo, lizard, and serpent are variously entwined Modigliani thinks that each of these staffs symbolizes the history of the village or clan to which it belongs, in which case they might be compared to the genealogical Maori staffs, like the one recording the history of the Ngatirangi tribe, now in the British Museum. As samples of the little-known literature of the Battaks, Modigliani was fortunate enough to secure twenty of their books, now rare They are ancient-looking tomes of various sizes, bound in wooden boards, the leaves are of beaten bark, the writing minute, mystic figures (*hatiha*) being occasionally intercalated These books, written by learned *gurus*, are of a sacred, medicinal, and encyclopædic nature, and much very valuable information on the Battaks will certainly be gained by their translation

At Engano, Modigliani was able to obtain three skulls, and took six excellent plaster casts from the living His series of photographs is also fine, but unfortunately some of the best were spoiled by the heat I have already noted the remarkable resemblance which the natives of Engano show with those of the Nicobar Islands There are amongst them faces which also recall Polynesian and especially Micronesian types Thus the photographs taken by my friend, over a hundred,

Fig. 4.—Battak gentleman

are of great ethnological value The collections illustrating the ethnography of the Engano islanders are, I should say, complete besides beautiful models of the singular houses and canoes, and actual specimens of the ornamented portions, viz doors, cross seats, &c, the mourning and ceremonial dresses and ornaments, house utensils, weapons, &c, are represented by a great number of carefully selected specimens

In conclusion, I can only say that Dr Modigliani has done much excellent work, and that we may look forward with pleasure to the publication of the results of his investigations, both in zoology and in anthropology

Henry H Giglioli

A MODERN REVIVAL OF PROUT'S HYPOTHESIS[1]

It frequently happens in the history of science that the line of thought engendered by one branch of study proves applicable in a totally distinct field In accordance with this principle a great stimulus is occasionally given in some particular line of research by the encroach-

[1] "On the Origin of Elementary Substances and on some New Relations of their Atomic Weights." By Henry Wilde, F R S (London: Kegan Paul, Trench, Trübner, and Co, 1892.)

ment of an investigator who brings the vitalizing ideas derived from his own work to bear upon a new subject It was with some such notions as these that we were predisposed to welcome Mr Wilde's attempt to deal with the greatest of all the problems presented by modern chemistry, but a careful consideration of the author's views has, we regret to say, left us in a state of disappointment for reasons which we will endeavour to explain to the readers of NATURE.

The work under consideration is a quarto pamphlet of eighteen pages and a folding table giving the author's and other arrangements of the chemical elements It consists of a preface dated May 1892, and a paper reprinted with additional notes from the Memoirs of the Manchester Literary and Philosophical Society for 1883 and 1887, the results having been first made known in the Proceedings of the same Society for April, 1878 The preface and paper are followed by translations of the same into French Everything emanating from a recognized authority in a distinct department of science is worthy of consideration by chemists, and there are scattered throughout the work many statements which we cannot but endorse There are, moreover, a few suggestions here and there which might be fruitful, and although the general result is disappointing, it is opportune that the author should have restated his hypothesis at a time when all chemists have more or less assimilated the views of Newlands, Mendeléef, Lothar Meyer, and their followers It may be stated at the outset that Mr Wilde's theory has nothing to do with an electrical origin of the elements as his reputation as an electrician might at first lead us to imagine

In very brief terms the author's theory is that the elements have been evolved from hydrogen by a process of nebular condensation In so far as he regards the elements as polymerides (as we might now express it) of hydrogen, there is nothing new in the idea It is Prout's hypothesis pure and simple We are far from asserting that this hypothesis has been disproved, there is a fascinating simplicity about it—it is so much in harmony with the general course of nature that matter should have been evolved from some primordial stuff that we should like it to be true, but unfortunately the most exact determinations of atomic weights have in later times not always conformed to the requirements of the hypothesis Mr Wilde in effect, if not in words, says *tant pis pour les faits!* These numbers ought to be whole multiples of the atomic weight of hydrogen, and Mr Wilde unhesitatingly makes them so. In some cases the discrepancy between the observed atomic weights and those calculated from the theory is so great—apart from the doubling or other manipulation of some of the old numbers —that this alone will damage his case in the eyes of those who know the scrupulous care taken and the variety of methods resorted to in order to secure purity of material in such determinations We give a few examples —

	Accepted Atomic Weight	Calculated		Accepted Atomic Weight	Calculated
Cu	63 18	62	Cr	52 45	54
Be	9 08	8	W	183 6	186
Sc	43 97	42	Si	28 2	35
Ga	69 9	96	Ni	58 6	56
Y	88 9	123	Co	58 6	56
In	113 6	150	Ir	192 5	196
Ta	182	185	Os	191 12	196

A large number of atomic weights not given above differ by one unit from the experimental results, in fact, more than half the existing determinations are in the light of the present theory erroneous to a most humiliating extent

We are not bigoted in our faith respecting the unassailable accuracy of the determinations of these constants; we all know the enormous difficulties which meet the chemist in his attempts to obtain his compounds in a state of purity. In one part of his paper the author suggests "that slight differences in the determinations may arise from the latent affinity which some elements have for minute quantities of another,' which is a reasonable supposition in its way, although not very happily expressed But later he somewhat inconsistently remarks "that these discrepancies are due to some unknown cause which prevents their [*i e* Cu, Zn, &c] true atomic weights from being ascertained'

From a purely philosophical standpoint the author's proposed emendations of the atomic weights are perfectly legitimate If it can be satisfactorily proved that these constants are the numerical consequences of some general law requiring that the relative combining weights referred to hydrogen should be whole numbers, it is correct to conclude that our determinations are, through experimental error, difficulty of separation, &c, faulty That some such law exists has been surmised again and again, but unfortunately the proof has not yet been found Now the central idea of Mr Wilde's paper is that there is an analogy between Bode's law of the planetary distances and the numerical relationships between the atomic weights, and he even attempts to show that this analogy is the result of a causal connection between the phenomena This is the most important suggestion in the work, as the whole novelty centres in this idea, and the subsequent acceptance of his views will turn upon the strength of his case in demonstrating these two points first, that Bode's "law" is the expression of a physical reality, and, secondly, that the numerical relations between the atomic weights are the physical expressions of a causal connection between the distances of the planets and the condensation of the primordial matter (? hydrogen)

The first point is purely astronomical, and we prefer to let astronomers speak on the subject Prof Simon Newcomb says ("Popular Astronomy") —

It is true that many ingenious people employ themselves from time to time in working out numerical relations between the distances of the planets, their masses, their times of rotation, and so on, and will probably continue to do so, because the number of such relations which can be made to come somewhere near to exact numbers is very great This, however, does not indicate any law of nature If we take forty or fifty numbers of any kind—say the years in which a few persons were born, their ages in years, months, and days at some particular event in their lives, the numbers of the houses in which they lived, and so on—we should find as many curious relations among the numbers as have ever been found among those of the planetary system.

The author thus gets but little support from astronomy and it is to be observed that in the list of planetary distances which he gives he stops short at Uranus, Neptune occupies an awkward position for Bode's "law" The flight which is taken in connecting this "law" with the atomic weights is, however, a bold one and worthy of being given in the author's own words After stating the nebular hypothesis he says —

That this gaseous or primordial substance consisted of a chaotic mixture of the sixty-five elements known to chemists is a notion too absurd to be entertained by any one possessing the faculty of philosophic thinking, as the regular gradation of properties observable in certain series of elements clearly shows that elementary species are not eternal, but have a history, which it is the proper object of physical science to unfold

With this we most cordially agree, and as the same idea has been repeatedly expressed by chemists and physicists, we do not imagine that it is likely to be controverted Then he continues.—

One of the principal facts which, to my mind, establishes the nebular theory of the formation of planetary systems on a firm basis is Bode's empirical law of the distances of the members of the solar system from each other and from the central body, as in this law is comprehended the idea of nebular condensation in definite proportions Now, if elementary species were created from a homogeneous substance possessing a

capacity for change in definite proportions, it is probable that the greater number of elements would be formed during or after the transition of the nebular matter from the annular to the spheroidal form. Moreover, as great cosmic transitions are not made *per saltum*, it might be expected that some modification of the law of nebular condensation into planetary systems, as exhibited in Bode's law, would be found on the further condensation of the primitive matter into elementary species.

There appears to be a flaw in this chain of reasoning which weakens the whole paragraph. It is difficult to see how a law, which the author himself describes as "empirical," can establish a theory on a "firm basis." We admit that an empirical law may be of use—Bode's law is a case in point—but surely it must pass beyond the stage of empiricism before it can establish anything on a firm basis. The astronomical foundation having therefore been shown to be insecure, or, in the opinion of astronomers, even non-existent, it remains next to consider the second point, with respect to which we shall let the author speak for himself:—

One objection raised against the theory which I have propounded on the origin and compound nature of the elements I will remark upon, is an alleged want of causal connection between the series of planetary distances and a series of atomic weights. Now, considering that specific gravities and atomic weights are admittedly correlated properties of the elements, and that specific gravities are fundamentally correlated with the dimensional properties of space, it follows that planetary condensations within interplanetary space are correlated directly with atomic condensations and atomic weights within that space. Hence the law that every increase of atomic weight, in a well-defined odd or even series of elements, is attended by an increase of specific gravity, is a natural consequence of the theory.

This is quoted from the preface; the mechanism of the process is described in the paper as follows:—

In the present hypothesis it is assumed:—(1) That a mass of hydrogen, of a curvilinear form, acquired a motion of rotation about a central point, which caused it to take a spiral or convolute form. (2) As each successive spiral or convulution was formed, the particles of hydrogen combined with themselves, as far as the septenary combination, to constitute the type of each series of elements—the number of types or series being equal to the number of convolutions of the rotating gas. According to this view, the elementary groups may be represented as forms of Hn, H2n, H3n, H4n, H5n, H6n, H7n; the internal convolutions forming the highest type, H7n, and the outer convolution the type Hn. (3) That on a further condensation of the elementary matter a transition from the spiral to the annular form occurred, during or after which the series under each type was generated in concentric zones and in the order of their atomic weights, until the highest member of each species was formed. (4) That as the elementary vapours begin to condense, or assume the liquid form, their regular stratification would be disturbed by eruptions of the imprisoned vapours from the interior of the rotating mass. The disturbance would be further augmented by the subsequent combination of the negative with the positive elements, and also by the various solubilities of their newly-formed compounds; so that the evidence of such stratification of the elementary vapours as I have indicated must necessarily be more fragmentary than that of the geological record.

In support of this last statement the author mentions the well-known association of allied elements in minerals.

The idea of an evolution of matter by a process of nebular condensation as above set forth is to be found under various forms in the writings of Herbert Spencer, of Sterry Hunt, Lockyer, and others. Also, it may be remarked in passing, that the hypothesis of stratification in the order of density was applied to the sun by Johnstone Stoney about the year 1867. In fact the general notion of elementary evolution is so obvious that it cannot fail to present itself again and again to those who think over such problems as are here dealt with. For the sake of chemical philosophy we only wish that this speculation could be placed on a firmer basis of observation or experiment—if for no other reason in order that the minds of chemists might be cleared of this inorganic *Urschleim* in which since the time of Prout they have been compelled to wallow.

Reduced to its ultimate terms it will appear, then, that Mr Wilde's view is a combination of the nebular with Prout's hypothesis, the latter being stated with a precision and boldness which certainly goes beyond any utterance on this subject to be met with in chemical literature since the time of its promulgation. Although the author takes hydrogen as the first stage in his evolutional series he admits, with Prout, that this element "may have been evolved from an ethereal substance of much greater tenuity." Under the seven stages of condensation comprised from Hn to H7n the author arranges all the chemical elements in a tabular form leaving gaps for unknown elements, and correcting the atomic weights where necessary so as to make them accord with the hypothesis. Some of the results of this treatment have already been alluded to. The way in which Bode's method is applied will be understood by taking one example, viz. the first series, Hn:—

0	0		7		Li	−	7
1	23	−	0	=	Na	−	23
2	23	−	7	−	K		39
3	23	−	7	=	Cu	=	62
4	23	−	7	=	Rb	=	85
5	23	−	7	-	Ag	−	108
6	23	−	7	=	Cs	−	131
7	23	−	7	=		=	154
8	23	−	7	−	-	=	177
9	23	−	7	−	Hg		200

The rule of construction is: multiply the atomic weight of the second member (Na = 23 in the above) by the arithmetical series and subtract the atomic weight of the first member (Li = 7 in the above) from the products; the results are the atomic weights of the elements of the series. This method is applied also to the group H2n with tolerable success, *provided the atomic weights are modified to even numbers and that the atomic weight of beryllium is made 8*. Mr Wilde's second group is given below:—

Be, 8; Mg, 24; Ca, 40; Zn, 64; Sr, 88; Cd, 112; Ba, 136; *x*, 160; *x*, 184; Pb, 208.

This is presumably one of the new relations between the atomic weights referred to in the title of the paper. In the third group, however (H3n), very considerable modifications of the atomic weights have to be made, as will be seen from the author's results:—

C, 12; Al, 27; Sc, 42*; Ce, 69*; Ga, 96*; Y, 123*; In, 150*; Er, 177*; Tl, 204; Th, 231.

The six numbers marked with an asterisk stand for 44, 92 or 141, 70, 61·7 or 89·5, 75·6 or 113·4, and 170·6 respectively. A system which necessitates this amount of manipulation of experimental results will certainly fail to commend itself for adoption by chemists. The proposed change of beryllium from 9·2 to 8 is directly opposed by the determination of the vapour density of the chloride by Nilson and Pettersson, and if adopted would cause this element to become still more divergent from the law of Dulong and Petit. The vapour density of indium chloride as determined by Nilson and Pettersson is in accordance with the accepted atomic weight of that element and opposed to that given by Mr Wilde. The elements associated in the first and second groups respectively, may be allowed to pass as natural allies, but the separation of carbon from its analogues, silicon, titanium, &c., and its association in the third group with aluminium, scandium, gallium, &c., is a violation of known relationships. The four halogens according to their atomic weights belong to the author's first (Hn) group. They are regarded as the negative analogues of the alkaline metals and are therefore placed in a separate column.

in such a way as to bring out the relation that there is a constant difference of 4 between each halogen and its positive analogue —

Na, 23 − 4 = 19, F, K, 39 − 4 = 35, Cl, Rb, 85 − 4 = 81 Br, Cs, 131 − 4 = 127, I

In a similar way the oxygen group is made into a negative column having positive analogues in the H2n group and showing a constant difference of 8 —

Mg, 24 − 8 = 16, O; Ca, 40 − 8 = 32 S, Sr, 88 − 8 = 80, Se, Ba, 136 − 8 = 128, Te

Of course chemists have long been familiar with various numerical relationships between groups of allied elements, but this does not appear as sufficient evidence for altering the atomic weights of Br, Cl and Se, unless these relationships can be conclusively shown to be the necessary result of a general law

But apart from such defects as have been pointed out, it will be seen that the proposed grouping breaks down altogether after the third group The author is hardly fair when he says (Preface, p iv) —"While the multiple relations subsisting among the atomic weights of the other series of elements are highly interesting, they do not possess, in the present state of our knowledge, that degree of precision which is the distinguishing feature of the series Hn and H2n An exception might, however, be made in favour of the series H3n, &c"

As a matter of fact it is not a question of "degree of precision" at all, for, as far as we can see, the other groups do not lend themselves to the Bodeian method, at any rate, not in the form applied to the groups Hn, H2n, and H3n We give the author's results as compared with those obtained by the application of his own method —

Group H4n.

x = 16, x = 32, Ti = 48, Ge = 72, Zr = 92, Sn = 116, La = 140, x = 164, D = 188, U = 240

The numbers obtained by the rule (1, 2, 3, 4, &c × 32, and 16 subtracted from each product) are 32, 48, 80, 112, 144, 176, 208, 240, &c, which, after Titanium, do not represent any atomic weights in the group till Uranium is reached

Group H5n

B = 10, P = 30, V = 50, As = 75, Nb = 95, Sb = 120, x = 140, x = 165, Ta = 185, Bi = 210

Calculated (1, 2, 3, 4, &c × 30 and 10 subtracted from each product) the numbers are —30, 50, 80, 110, 140, 170, &c

Group H6n

x = 18, x = 36, Cr = 54, Mo = 96, x = 144, W = 186

Calculated (1, 2, 3, 4, &c × 36 and 18 subtracted from each product) the numbers are —36, 54, 90, 198, &c.

Group H7n

N = 14; Si = 35; [Fe = 56, Mn = 56, Ni = 56, Co = 56], [Pd = 105, Rh = 105; Ru = 105, Da = 105], [Au = 196, Pt = 196, Ir = 196, Os = 196]

Calculated (1, 2, 3, 4, &c., × 35 and 14 subtracted from each product) the results are —35, 56, 91, 126, 161, and 196

The association of nitrogen with silicon and the metals of the iron and platinum groups is, to say the least of it, incomprehensible. We have thought it desirable to give this analysis, for no reason is given in the paper for this particular grouping after the third series, beyond the well-known chemical relationships of the elements which, as we have seen, is sometimes violated in a most unaccountable way. The groups are obviously not constructed by the Bodeian method, the atomic weights are modified in many cases by one or two units, and the result is a classification which differs only from the received classification on points which cannot possibly be conceded by chemists The reason why silicon is separated from its analogues is as follows —

Now, if silicon were the true analogue of titanium, the oxides of these elements should be isomorphous, whereas the crystalline form of quartz is hexagonal, while rutile, anatase, brookite, zirconia, and tinstone (similar oxides of members of the series H4n) are tetragonal, consequently, silicon does not belong to the series H4n

This is a point, and out of justice to the author we give it for what it is worth,[1] but the atomic weight of silicon has been determined by the vapour density of its chloride, and the result is fatal to Mr Wilde's classification His attempt to justify the atomic weight 35 by an appeal to the specific heat is unfortunate, because he takes the old determination by Regnault (0 176) instead of the more recent determination by Weber (0 203 at 230° C) Moreover, he is inconsistent in not allowing the same correction for boron and the other elements which deviate from Dulong and Petit's law

We cannot go much further into the details of this paper Enough has been written to justify the disappointment which we expressed at the outset, and it is only the intrinsic importance of all questions bearing upon the origin of the elements that has warranted such extended treatment It appears that the numerical relations which are brought out by the author's method have either long been known or else—as in his application of the Bodeian method—they do not exist beyond a limited number of groups The results do not take us beyond the point at which chemists were left by Dobereiner, Pettenkofer, Dumas, and numerous other chemists who, for three-quarters of a century, have directed attention to such numerical relationships. In some respects—such, for example, as in the exactness with which the atomic weight of an element is the arithmetical mean of the elements above and below it in the same series—Mr Wilde's numbers express the relationship more closely than those of any other author, but this agreement is simply brought about by forcing the atomic weights into the requirements of the case. The increase in density as the odd and even series are ascended, is nothing more than an imperfect way of stating the well-known relationship between atomic weight and atomic volume, which is so much better shown by Lothar Meyer's curves The table of elements presented by Mr Wilde ignores that fundamental principle of periodicity or recurrence of properties which is the key-note of Mendeléeff's system, and which has led to the general adoption of that system by chemists We do not pretend that Mendeléeff's classification is faultless, the illustrious founder of the Periodic Law would be the first to admit that his system has certain imperfections Mr Wilde has emphasized a few of these in his preface, and he somewhat summarily dismisses the whole scheme in the following words —

From the numerous discrepancies which present themselves in the classification of the elements when arranged in the regular order of their atomic weights, it will be obvious that the idea of recurring properties or periodic functions, in terms of the vertical series of Newlands or the horizontal series of Mendeléeff, has no more relation to chemical science than the law of the increase of population, or the laws of variation and inheritance in organic species.

This paragraph, penned in the present year, will, perhaps better than any other statement that could be reproduced from the paper, enable chemists to form a correct estimate of the value of the work and of the author's qualifications for dealing with the question of the origin of the chemical elements.

R. MELDOLA.

[1] "Stannic and titanic oxides resemble silica both physically and chemically they might be expected to form analogous compounds, and be isomorphous with silica, as Marignac (1859) found actually to be the case" Mendeléeff's "Principles of Chemistry," vol ii p. 95.

NOTES

BY the death of Lord Tennyson not only does England lose one of her noblest sons, but the world loses the Poet who, above all others who have ever lived, combined the love and knowledge of Nature with the unceasing study of the causes of things and of Nature's laws. When from this point of view we compare him with his forerunners, Dante is the only one it is needful to name; but although Dante's knowledge was well abreast of his time, he lacked the fulness of Tennyson, for the reason that in his day science was restricted within narrow limits. It is right and fitting that the highest poetry should be associated with the highest knowledge, and in the study of science, as Tennyson has shown us, we have one of the necessary bases of the fullest poetry—a poetry which appeals at the same time to the deepest emotions and the highest and broadest intellects of mankind. Tennyson, in short, has shown that science and poetry, so far from being antagonistic, must for ever advance side by side. We are glad to know that the Royal Society, of which Lord Tennyson has been for many years a Fellow, was fittingly represented at his funeral by its President and officers.

WE regret to announce the sudden death of Mr. Robert Bullen, the curator of the Glasgow Botanic Gardens. He was well known as a horticulturist, being especially successful in the cultivation of orchids. The post vacated by his death is one of the best of the kind in the country, and we understand that the appointment will rest with the Corporation of Glasgow, who took over the management of the Botanic Gardens in 1891.

THE death of Dr. Léon Poincaré, professor in the Faculty of Medicine at Nancy, is announced. He died on September 15 at the age of sixty four.

AT the meeting of the Linnean Society of New South Wales on August 31, Mr. H. Deane, Vice-President, who occupied the chair, referred to the loss the Society had sustained by the death of Mr. R. D. Fitzgerald, well known for his knowledge, and for his artistic delineations, of Australian orchids.

RUSSIA, which already possesses some of the best equipped chemical laboratories in Europe, is to have another which is to eclipse all others. On September 13/25 the foundation stone of the new chemical laboratory of the University of St. Petersburg was laid with befitting ceremony. The new laboratory, which is designed by Prof. Mentschatkin in collaboration with the architect Krassowsky, is based upon the best existing models in Germany and Austria.

IN the *Times* of the 10th inst. there is an announcement that Surgeon-Major Laurie has proved that the fall of blood-pressure in animals rendered insensible by chloroform is due to the action of the anæsthetic on the brain, and not on the heart. When blood containing chloroform is allowed to reach the brain only all the ordinary phenomena of anæsthesia are observed, but when such blood is conveyed to every other part of the body except the brain, which, by a peculiar arrangement of the experiment, is supplied with pure blood, the anæsthetic effects of chloroform and also its depressing effects on the circulation are not observed. We are glad to see that Dr. Laurie is still continuing his experiments on a subject of such vital interest, and we trust that his energy and the generosity of the Nizam, to which we owe the elaborate work of the Hyderabad Chloroform Commission, will meet an ample reward.

THE British Ornithologists' Union, founded in 1858, consists of upwards of 250 votaries of this branch of natural history, who maintain as their organ the well-known ornithological journal, *The Ibis*, now in its thirty-fourth volume. The more active members of the union have just formed themselves into a club, and will meet together once a month to read and discuss papers and to exhibit specimens. The first meeting of the "British Ornithologists' Club" will be held on October 19. Mr. Howard Saunders, F.Z.S., is the treasurer and secretary.

THE university of Padua is about to hold a festival in honour of Galileo. The seventh of December, 1892, will be the tercentenary of the day upon which Galileo ascended the chair of mathematics at that university. In the words of the letter of invitation which the rector, Prof. Carolus Ferraris, has just issued to some of the learned societies of Europe, "Illo enim die Ann. mdxcii summus acerrimusque investigator legum, quibus caelestium terrestriumque rerum natura continetur, hic cathedram ascendit eamque voce sua immortalitati commendavit." It is to the honour of Padua that it welcomed Galileo to this high position the very next year after he had been publicly hissed and obliged to resign his professorship at Pisa. The festival will extend from the 6th to the 8th of next December.

THE Linnean Society of New South Wales has just issued a second circular with respect to the Macleay Memorial Volume by which it appears that only £170 has been contributed out of £400 which is required for the publication of the Memorial Volume. The circular calls to mind Sir William Macleay's contributions to science, in purchasing and fitting out at his sole expense the ship *Chevert* and exploring the island of New Guinea, and in presenting to the University of Sydney his entire collection valued at £23,000, together with £6000 to provide salary for a curator. Sir William Macleay was also the founder of the Linnean Society of New South Wales, for which he erected a suitable building, and which he endowed with the sum of £20,000. He further founded a chair of bacteriology and four scientific fellowships at the University of Sydney, at a cost altogether of £47,000. The sum of £170 seems hardly adequate as a recognition of these munificent gifts to science, to say nothing of the original researches which Macleay himself conducted.

MR. THOMAS HODGKINS, of Long Island, New York, has sent to the Royal Institution no less than £20,000 for the promotion of scientific research. Not very long ago, as we noted at the time, Mr. Hodgkins presented £40,000 to the Smithsonian Institution at Washington.

THE Severn Valley Field Club has completed the work of the current year. It has paid some attention to the glacial deposits at Gloppa, near Oswestry, which have recently yielded to Mr. A. C. Nicolson a large series of fossils. The members have also visited the Triassic rocks of the area round Warwick. Their work concluded with an investigation of the Uriconian and Longmyndian formations of Western Shropshire under the guidance of the President, Dr. C. Calloway.

DR. J. M. MACFARLANE has been appointed to the chair of Biology in the University of Pennsylvania, Philadelphia. He formerly held the post of senior assistant in the Botanical Department of the University of Edinburgh.

AN influential association has been formed for the promotion of the study of the Hausa language and people, in commemoration of the services of the Rev. J. A. Robinson, who died last year at his work as a missionary in the Niger Territories. Hausa is the *lingua franca* of the Central Sudan, extending from the Sahara to the tribes near the Gulf of Guinea, and from the Egyptian Sudan to the French colony of Senegal. Mr. Robinson convinced himself that no satisfactory work of any kind could be carried on among the races of the Central Sudan without a knowledge of Hausa. The Executive Committee of the new Association have decided to endeavour, with the least practicable delay, to appoint two "Robinson Students," conversant with Arabic or Hebrew, whose preliminary labours would be carried on in the comparatively temperate climate of Tripoli, with a view to their proceeding at a later date to the Central Sudan, where they would make the language and cus-

toms of the Hansas subjects of careful study All scientific observations collected by these students during their residence in Africa will be sent to the Association for distribution to the appropriate societies

THE Association of American Agricultural Colleges and Experiment Stations will hold its sixth annual convention at New Orleans on November 15 The different subjects assigned to station workers for the Columbian Exhibition will be discussed

PROF H MARSHALL WARD, F R S, of the Royal Engineering College, Cooper's Hill, will give a course of ten lectures at University College, London, on "The Morphology and Physiology of Fungi and Schizomycetes" The course will begin on Thursday, October 13, at 3 p m, and be continued at the same time each week till Christmas

A LARGE plant of *Fourcroya* is now in flower in the conservatory of the Royal Botanic Society The secretary of the Society referred to it at the meeting of the Council on Saturday last. The plant is sometimes called the century plant, the idea being that it flowers only once in a hundred years In reality the flower is produced only once in the life of the plant, the duration or term of life varying considerably, according to the treatment the plants individually receive Specimens of the *Agave Americana* have flowered in the Royal Botanic Society's garden, the ages of them being well authenticated as over 80 years; but the plant is known to flower in warmer climes before twenty years of age The present specimen of *Fourcroya* is between twenty and thirty years old It began on August 1 last to produce its flower spike, which, although the plant is slow growing generally, developed at a rapid pace, so that on September 15 the tip had reached the glass roof A square of glass being removed, the flower spike continued its growth, and it is now some 3 feet or 4 feet above the ridge, a total of over 30 feet in height The leaves vary from 6 feet to 7 feet in length

IN his treatise, "On the Propagation of Electric Force," Prof. Hertz mentions some experiments tending to prove that the production of resonance and the period of oscillation in resonators are not influenced by the specific resistance or the magnetic properties of the secondary conductor But if the phenomena be observed electrometrically, the individual properties of the metals soon show themselves This method was employed by Mr V Bjerknes, of the University of Christiania, who gives an account of his results in No 9 of *Wiedemann's Annalen* Experiments made with copper, brass, German silver, platinum, nickel, and iron show that metals have different powers of absorbing the energy of electric waves The rate of absorption increases with the resistance and with magnetization of the metal Iron and nickel were able to follow the oscillations to a certain extent, which means that their magnetization was actually reversed one hundred million times per second.

A method of exhibiting the Hertzian oscillations to a large audience is described in the same number by Mr L Zehnder, of the University of Freiburg The two conducting rods placed in the focal line of the concave mirror are connected with a Geissler tube, within which the ends are placed very closely together, but so that a discharge produces not a spark but a general luminosity inside the tube The secondary Hertz effects are too feeble to be visible except at a very short distance and in a darkened room. In this case they are augmented by a kind of relay. On either side of the terminals of the resonator are two other terminals from a circuit of 600 secondary cells, which can be regulated so that the current is just unable to traverse the distance between the terminals. As soon, however, as the resonator responds to electric oscillations, the relay is brought into action, and a brilliant discharge takes place. In cases where such a large accumulator is not available, it is possible to work with another inductorium, or, still better, to obtain the oscillating current from the primary coil by bringing one end of a wire into its neighbourhood, the other being led to earth. By such means it is possible to exhibit the phenomena in question without even darkening the room

THE weather during the first part of the past week was very boisterous and inclement over the whole of these islands Between Thursday, the 6th inst, and Monday last, two deep depressions closely following each other passed over the country from off the Atlantic, and heavy gales were experienced in all parts of the United Kingdom, accompanied by much rainfall, while thunderstorms and hail occurred in many places The sea also was exceptionally rough, especially on our north-west coasts, and caused much damage on shore Temperature was somewhat low for the time of year, the daily maxima rarely reaching 60° in any part, while the nights were very cold As the depressions passed to the eastward the weather cleared and the temperature decreased considerably, sharp frost occurring on the ground over the inland parts of England Towards the close of the period the type of weather was becoming more settled in character than it had been for some time past, but on Tuesday a depression lay over the Bay of Biscay, which might disturb our conditions The *Weekly Weather Report* of the 8th inst showed that during that week the rainfall exceeded the mean in all districts except the south of Ireland, and that temperature was from 2° to 4° below the mean, the lowest of the minima ranging from 32° to 38° The only district in which bright sunshine exceeded the mean was the Channel Islands, the percentage of the possible duration amounted there to 40, while it was only 8 in the north of Scotland

THE Meteorological Council have published the hourly means obtained from their self-recording instruments at four observatories for the year 1889, for periods of five days, calendar months, and for the year, while means of pressure and temperature and totals of rainfall are also given for every day This is the third year in which the observations have been published in this form, instead of the actual hourly values, as formerly, and an addition has been made by including the monthly and yearly mean values of the daily maximum and minimum temperatures for this and the two previous years in this volume The work contains 112 quarto pages of very clearly drawn up tables

MR H DEVAUX has been making interesting experiments on the sense of taste in ants Among other results he has found that *Lasius flavus*, while fond of sugar, dislikes saccharine The ants swarmed around sugar laid out for them, but turned away from saccharine as soon as they tasted it Even sugar became unpleasant to them when it was mixed with saccharine It seems, therefore, that sweetness is not the only quality which attracts them to sugar

PROF SCOTT has a note in the new volume of "the Transactions and Proceedings" of the New Zealand Institute, on the occurrence of cancer in fish The fish afflicted with this disease were all specimens of the American brook-trout (*Salmo fontinalis*) kept in confinement in one of the ponds at Opoho belonging to the Dunedin Acclimatisation Society Males and females were alike affected, and the diseased fish never recovered. Prof Scott has been able to examine several specimens showing the disease in various stages of advancement, and gives in his paper a short account of the naked-eye and microscopic appearances of the growth. The occurrence of cancer in the lower animals has been frequently observed of late years, and it is by no means so rare among them as it was at one time thought to be. Prof. Scott does not, however, know that it has ever before been noted in fish.

In his report as surgeon-naturalist of the Marine Survey of India, to which we referred last week, Dr A Alcock records some interesting observations on the little estuarine crab *Gelasimus* The most obvious structural peculiarity of *Gelasimus* is the enormous development of one of the chelæ in the male only, the chelæ in the female being minute The species observed by Dr Alcock was *Gelasimus annulipes*, Edw This species lives in vast swarms in "warrens" on the muddy tidal swamps of the Godávari and Kistna, each individual having its own burrow, round which it ranges, and into which it retreats when alarmed In the colder months, at any rate, the males far outnumber the females In a fully adult male the length of the large chela is two-and-a half times the greatest length, and one-and-a half times the greatest breadth, of the whole body, and 40 per cent of the entire weight of the animal, and is coloured a beautiful cherry-red fading to a rose pink, the rest of the animal being of a dingy greenish-brown colour Dr Alcock has been able to observe that, whatever other functions the great chela may serve, it also, in the species under consideration, is (1) a club used in the contests of rival males, and (2) a signal to charm and allure the females This last function is particularly apparent As one walks across the mud one first becomes aware of the presence of these crabs by noticing that the surface of the mud is everywhere alive with twinkling objects of a brilliant pearly-pink colour Carefully watched, these prove to be the enormous chelæ of a crowd of males of *Gelasimus* waving in the air, each little crab standing at the mouth of its burrow and ceaselessly brandishing its big claw. On closer observation, among every ten or so males a small clawless female may be seen feeding in apparent unconcern If the female should approach the burrow of a male, the latter displays the greatest excitement, raising itself on its hindmost legs, dancing and stamping, and frantically waving its beautifully coloured big claw From prolonged watching, Dr Alcock feels convinced that the waving of the claw by the male is a signal of entreaty to the female, and he thinks that no one can doubt that the claw of the male has become conspicuous and beautiful in order to attract and charm the female The second function, as a fighting weapon, becomes apparent when in the general tournament one of the rival males approaches too close to another The great claw is then used as a club, the little creatures making savage back handed sweeps at each other

An excellent paper on fungous diseases and their remedies was read lately by Prof J E Humphrey before the Massachusetts Horticultural Society, and has now been printed One of the principles on which he insists is that the treatment of these diseases, to be efficient, must be preventive rather than remedial. He points out that it is not enough to take care that plants shall have abundant nourishment No practice, he says, is more common among American fruit growers than to leave in the vinery and the orchard, lying on the ground or hanging from the branches, the dead fruits of the season, which have been rendered worthless by fungi Nothing could produce more unhealthful conditions, for these dead fruits commonly furnish to the fungi which attack them precisely the most favourable soil for further and complete development In the next spring the air is full of the spores of these fungi, which find lodgment on the new leaves and fruits of the very plants on which they grew last year, and so the story goes, year after year. "In a word," says Prof Humphrey, "keep your orchards and gardens and greenhouses *clean*. Allow no rubbish to be about on which fungi can breed. Remove and destroy all diseased fruits or plants as scrupulously as you preserve saleable ones, and you will have more saleable ones to preserve. It is surprising how far generous culture and clean culture will go toward preventing fungous diseases, without special treatment."

The Marquis de Nadaillay contributes to *Science* (Sept 23) an interesting account of the various discoveries which have been made in the caves of Baoussé Roussé, between Mentone and Ventimiglia The caves were found in 1872 by M Rivière, who has since vigorously prosecuted his excavations These have yielded many human skeletons, all belonging to the Cro Magnon race. They are robust, and bespeak an athletic constitution and great muscular power The men were remarkably tall, the crania are dolichocephalic, and the tibias platycnemic The bones of all the adults, after the total decomposition of the flesh, were painted red with the help of peroxide of manganese or other substances frequently met with in the caves a custom which the Marquis de Nadaillay believes prevails, or till lately prevailed, among some Indian tribes Much attention has been devoted to the latest discovery, made early in the present year, of three skeletons—a man, a woman, and a "young subject," whose wisdom teeth had not been developed They were found eight metres below the ground, and had been buried on a bed of cinders, broken fragments of charcoal, and remains of all sorts, evidently the hearth on which the family cooked their victuals The boy wore a necklace formed of two rows of the vertebræ of a fish and one row of small shells At different points hung pendants cut out of the canine teeth of stags, decorated with parallel striæ The man had also a necklace of fourteen canines of the stag, also striated With the skeletons were found stone instruments, some of them finely worked, but none of them polished, and some bone implements of very rude fabrication The man was very tall If we judge by the length of his thigh bone, his height must have exceeded six feet six inches The teeth even of the boy were very much worn, those of the man were worn to the roots The bones of many mammals have been found, but none belonging to extinct species, or even to the reindeer On the other hand, no polished stone implement has been discovered The remains, therefore, must be ascribed to the end of the quaternary or the beginning of the neolithic times One cave is still unexcavated The Prince of Monaco, whose property it is, has given orders that the excavations are to begin next spring

Mr C Hedley read before the Linnæan Society of New South Wales, on August 31, a paper in which he presented an interesting study of ancient geography The immediate subject was the range of *Placostylus* He remarked on the essential unity of the *Placostylus* area as a zoological province, embracing the archipelagoes of Solomon, Fiji, Hebrides, Loyalty, New Caledonia, Norfolk Island (?), Lord Howe, and New Zealand, a unity explicable only on the theory that they form portions of a shattered continent, and are connected by shallow banks formerly dry land Deep sea soundings, especially those of the *Challenger* in the Coral Sea, further demonstrate the existence of such a submarine plateau, for which the name of "The Melanesian Plateau" is proposed Further, Mr. Hedley contended that the Melanesian Plateau was never connected with, nor was ever populated from, Australia, that its fauna and flora were originally derived from New Guinea.

In the *Proceedings* of the U S National Museum (vol xv), Lieut Dix Bolles calls attention to an interesting object included in a collection of ethnological specimens given by him to the museum in 1883-85 This is a wooden mask, which has for its eyes two large bronze Chinese coins The grave from which the mask was taken is near the Chilcat village, at the mouth of the Chilcat River, Alaska, where stands a row of six grave-houses on a narrow strip of land close to the river, with a swamp behind them. From this particular grave very little was obtained by the explorers, its contents having nearly all rotted away. Lieut. Bolles was told by the natives that it

was the grave of a medicine man who had flourished more than 200 years before, six successors having filled his office, each one living to a good old age. Careful questioning failed to evoke any other answer. When the coins were shown to the Chilcats, they could not remember having ever seen such objects. Lieut. Bolles concludes that the coins probably were derived from a junk driven on the coast about two centuries ago. "To those," he says, "who doubt the advent of junks on the west coast at this early date, these facts will probably not be satisfactory, but it will be necessary for them to break down by direct evidence such a strong plea."

MESSRS. H. ALABASTER, GATEHOUSE & CO. have now in the press, shortly to be issued, a new work, entitled, "Domestic Electric Lighting, treated from the Consumer's Standpoint." The author is Mr. Ed. C. de Segundo.

"THE ELECTRICIAN" Printing and Publishing Co., Limited, have in preparation for their "Electrician" Series the following volumes:—"Electromagnetic Theory," by Oliver Heaviside; "Electrical Engineering Formulæ, &c.", by W. Geipel and H. Kilgour; "Submarine Cable Laying and Repairing," by H. D. Wilkinson; "Drum Armature Winding and Commutators in Theory and Practice," by F. M. Weymouth; and "Electricity as a Motive Power," by Albion T. Snell, M.I.C.E., M.E.

THE first series of lectures given by the Sunday Lecture Society begins on Sunday afternoon, October 23, in St. George's Hall, Langham Place, at 4 p.m., when Dr. Andrew Wilson will lecture on "The Distribution of Animals and what it teaches." Lectures will subsequently be given by Mr. Willmott Dixon, Prince Kropotkin, Mr. R. Brundenell Carter, Mr. Arthur W. Clayden, Prof. H. Marshall Ward, F.R.S., and Dr. E. E. Klein, F.R.S.

ANOTHER memoir upon persulphuric acid and the persulphates is contributed by M. Berthelot to the *Annales de Chimie et de Physique*. As described in our note of vol. xliv., p. 577, the potassium, ammonium, and barium salts of this interesting acid were obtained last year by Dr. Marshall, of Edinburgh, in tolerably large quantity and in well developed crystals. M. Berthelot, to whom the honour of the first preparation of persulphuric acid and its anhydride is due, now publishes his further work upon the subject, fully confirming Dr. Marshall's results, and adding a few more facts to our knowledge of the acid and its salts. The form of electrolysis apparatus which has been found by M. Berthelot to yield the best results consists of a double cell, the inner vessel of which is constructed of porous porcelain. The liquid contents of both the interior and exterior vessels are cooled by means of glass worms through which a constant current of cold water is maintained. The inner cell of 150 c.c. capacity contains a concentrated solution of potassium or ammonium sulphate, according as potassium or ammonium persulphate is required, in sulphuric acid diluted with six or seven times its volume of water. The nearer the composition of this liquid approaches to that of a solution of bisulphate of potassium or ammonium, the greater is the yield of persulphate. The exterior cell is simply filled with dilute sulphuric acid. The positive pole in the interior cell is most advantageously formed by a stout platinum wire, about one millimetre in diameter, as persulphuric acid is found by M. Berthelot to be rapidly decomposed in contact with a large surface of platinum. Platinum sponge, indeed, instantly decomposes the acid or solutions of its salts. The negative pole in the outer cell may conveniently take the form of a large plate of platinum. The current employed was one of three amperes derived from accumulators. At the expiration of fifteen to twenty hours the internal cell is found to contain large quantities of beautiful crystals of the persulphate. The usual yield of the potassium salt was 20-25 grams, and of the more soluble ammonium salt as much as 40-45 grams, in one operation. M. Berthelot has also obtained potassium persulphate by the direct electrolysis of sulphuric acid and subsequent addition to the product of a concentrated solution of potassium bisulphate, crystals of potassium persulphate, KSO_4, being at once deposited. This mode of preparation is not so advantageous as the method of production by the electrolysis of potassium sulphate as above, but affords interesting proof of the formation of free persulphuric acid by the electrolysis of oil of vitriol. M. Berthelot has further succeeded in preparing persulphuric acid by the gradual addition of anhydrous barium peroxide to concentrated sulphuric acid in a small flask surrounded by ice. So rapid is the action that if the addition of the peroxide is continued until the sulphuric acid is almost exhausted, even although the vessel is maintained in pounded ice, dense vapours are evolved which possess the remarkable odour and other properties of persulphuric anhydride. Another interesting fact observed by M. Berthelot is that a solution of potassium persulphate attacks mercury, even at the ordinary temperature, with production of a yellow basic sulphate which appears to be identical with the salt known since the times of the alchemists as *turpith mineral*.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Miss F. A. Hill; two Racoons (*Procyon lotor*) from North America, presented by Captain Sharp; a grey Ichneumon (*Herpestes griseus*) from India, presented by Mrs. Wyndham Bewes; a Stanleyan Chevrotain (*Tragulus stanleyanus*) from Java, presented by Mr. Chas. J. Noble; a Vulpine Phalanger (*Phalangista vulpina*, ♂) from Australia, presented by Master H. H. Barret; a White Stork (*Ciconia alba*), European, presented by Sir H. Rae-Reid, Bart., F.Z.S.; an Ostrich (*Struthio camelus*, ♂) from Africa, presented by H.M. the Queen; a Common Chameleon (*Chamæleon vulgaris*) from North Africa, presented by Mrs. Davidson; three Negro Tamarins (*Midas ursulus*) from Guiana; a Canarian Laurel Pigeon (*Columba laurivora*, ♂) from the island of Gomera, Canary Islands; two Nicobar Pigeons (*Colœnas nicobarica*) from the Indian Archipelago, deposited; an Indian Muntjac (*Cervulus muntjac*, ♀) from India; four Ringed Plovers (*Ægialitis hiaticula*) and two Dunlins (*Tringa alpina*), British, purchased.

OUR ASTRONOMICAL COLUMN

LUMINOUS NIGHT CLOUDS.—In an article communicated to *Astronomische Nachrichten*, No. 3120, Herren W. Foerster and O. Jesse invite astronomers and geophysicists both here and abroad to make observations of the very interesting phenomena of luminous night clouds, the appearance of which has, up till now, been observed more or less only at Berlin. Since the year 1885, the authors tell us, these appearances have been most noticeable, and it is because they are now becoming less so that they wish to have as many observations made as possible. The phenomenon appears in the form of cirrus clouds, which stand out bright against the twilight sky. The colour generally noticed is that of a bluish white, and when the horizon is approached, gold and red tints are added. The best time for observation is said to be just before and after sunrise and sunset. From photographs taken at Berlin it has been computed that these clouds are at a height of 82 kilometres. Long after the sun has set they are seen to reflect the sunlight, but as soon as they fall within the reach of the earth's shadow they immediately become invisible. The observations show, so far as may be judged from those already at hand, that the movements of this phenomenon after midnight are directed from the north east ± 40°, and the authors think it highly probable that the resistance of the medium surrounding the earth accounts for these movements. This is to a certain extent affirmed by observations made at Punta Arenas and other places, the phenomena occurring six months after the conclusion of the Berlin observations. The authors suggest that eye observations

(taken every few minutes) should be made in different latitudes, to ascertain the apparent height to which these clouds attain The determinations of azimuth and altitude should also be current to three or four minutes of arc, and the time to two or four minutes Notice should also be taken of the general state of the atmosphere at the time of observation, while photography should be employed to record their place and motion The paper contains one or two more suggestions, among which is the employment of the spectroscope, and concludes with the hope that the importance of this phenomenon in relation to cosmical problems will arouse much interest and enlist many observers, for, in such a case as this, the observations of one institution will not help to solve such a general question as this

NOVA AURIGÆ —From the communications, in *Astronomische Nachrichten*, No 3120, we make the following notes with reference to the magnitude and spectroscopic appearance of the Nova Aurigæ

Dr J Holetschek, of the Vienna Observatory, has examined the star with regard to the former, and finds that, if any, an increase in brightness has taken place since August 24 The following are his figures, N standing for the Nova, and *a* a neighbouring star, the magnitude of which is taken as 9 7 The hours refer to Vienna mean time —

1892	h	N	m
August 24	13¾	0 5*a*	9 65
,, 26	14	2*a*	9 5
,, 27	14	1 5*a*	9 55
,, 28	12¾	2 5*a*	9 45
,, 30	12¼	2*a*	9 5
Sept 2	14	3*a*	9 4

Observations made on Sept 15 12h , Sept 16 11½h , and Sept 17 12½h showed that N was at least four degrees brighter than *a*, and two degrees brighter than the star, 9 5m B D + 30° 924

Using the 30 inch of the Pulkova Observatory, Mr A Belopolsky has made some measurements of the brightest line visible in the spectrum His measures are —

1892	W L	Mean
September 10	501 2$\mu\mu$	
,, 12	501 1	
,, 14	(499 5)	501 0
,, 15	500 9	
,, 16	500 7	

Of the other lines there were seen D or D_3, F, and a dark line about wave length 465$\mu\mu$

MINOR PLANETS —The application of photography to the search of minor planets seems to be rewarded with remarkable success, for no less than four new ones, 1892, E, F, G, and H, have, since September 25, been discovered The first two are due to M Perrotin, while the last two were photographed by M Wolf A fact worth recording is that the plate, on which the latter planets were found, contained also two other images, those of the planets (34) Circe, and (184) Dejopeja , thus the positions of four planets were obtained with one exposure

REPORT OF MR TEBBUTT'S OBSERVATORY —In this small pamphlet we have a condensed account of the present state of the observatory buildings, instrumental equipment, &c , together with the work done during the year 1891 Although the staff is not very great, yet the work carried out shows that all the available time has been made the most of The observations include forty-six occultations of stars by the moon, phenomena of Jupiter's satellites, transit of Mercury, conjunction of Venus and Jupiter, and filar micrometer comparisons of the minor planet Ceres, comprising 106 comparisons and four comparison stars Several comets were observed with the square bar-micrometer, while some interesting double stars and the two variables of Argus and R Carinæ have also been worked at The 9h a.m meteorological observations have been continued with the usual regularity

PHOTOGRAPHIC CHART OF THE HEAVENS —In a paper read on July 1, 1891, before the Royal Society of New South Wales, Mr. H. C. Russell relates many of his experiences, together with some of the results obtained during the preparation of the Sydney Observatory for the photographic chart of the heavens. The first difficulty that turned up had reference to the photographing of the stars of the fourteenth magnitude The two minutes' exposure was found quite long enough for ninth magnitude stars, but the thirty minutes was not sufficient to record those of the fourteenth. A question also arose as to coloured stars, for in many cases stars visible telescopically were not photographed at all Of the many objects photographed with the portrait camera, Mr Russell describes very fully the beautiful nebula 30 Doradus This nebula, as he says, is a great spiral structure, of which we see the greatest diameter, its thickness measured through in the line of sight being comparatively small He has been able also to obtain a very fine photograph of N Argus, a nebula, which, as may be concluded from the negative, "covers a much larger area than that of Orion " The same photograph also confirms the observations made by Mr Russell in 1872 that a conspicuous part of the nebula which Herschel drew and described in 1838 has wholly disappeared, and that its place is now occupied by a dark round spot What this may be is a doubtful question, but as Mr. Russell says "It cannot be a solid body, because the stars are there, but a slight misty body would hide the nebula and not affect the stars very much " The pamphlet concludes with an excellent picture of the κ Crucis cluster.

GEOGRAPHICAL NOTES

COLONEL BAILEY, R E ,lecturer on Forestry in the University of Edinburgh, has been appointed secretary to the Royal Scottish Geographical Society, in room of Mr A Silva White, whose resignation on account of ill-health we noticed some months ago

PROF CHERSKI, whose projected journey in Eastern Siberia was mentioned in Geographical Notes for June 30 (p 212) is reported to have died near Sredne Kolymsk, on his way down the Kolyma river towards Nizhne Kolymsk, where he intended to have passed the winter Cherski has travelled frequently and far in Siberia, and has done much to elucidate the geographical conditions, and in particular the geology of many parts of Northern Asia His great geological map of the Lake Baikal district is the work by which he will be best remembered

THE current number of the *Scottish Geographical Magazine* contains Mrs Bishop's account of her travels in Ladak and the adjacent territories, often called Lesser Tibet As a record of personal adventure and observation of native character the paper ranks worthily with the published records of this traveller's earlier and later journeys

THE *Proceedings* of the Royal Geographical Society for October publishes a short statement of the progress of Indian surveys during the last field season In Bengal the Behar detachment completed the traverse survey of 1610 square miles in districts Muzaffarpur and Champaran In Bombay 2536 square miles of detailed survey were completed on the scale of two inches to one mile, and 2100 square miles were triangulated in the Gujarat and Mahratta country Two parties were at work in Burma In district Sagaing 1842 square miles of cadastral survey and 1142 of traverse survey were completed, while 700 square miles of traverse survey were made in district Shwebo, and a topographical survey, on the scale of one mile to an inch, of 106 square miles of the Chindwin coalfields There were also carried out in districts Amherst, Tavoy, and Mergin 881 square miles of cadastral survey, besides a traverse survey of 510 square miles

THE MICRO-ORGANISMS OF THE SOIL[1]

THE high office with which you have honoured me entails the delivery of an address, which I keenly feel I cannot give in keeping with the standard set by my distinguished predecessors.

Fermentation, though observed since pre-historic times, is perhaps less understood than any chemistry has to deal with. The exciters of fermentation are rendered exceedingly difficult of investigation, because they, like all living things, are subject to physiological—or more specially pathological—functions of life, they are so sensitive that any abnormal influence either changes their whole mode of existence or destroys it altogether; a medium suitable to the life of one special kind is changed by

[1] Address delivered by Prof Alfred Springer as Vice-President of Section C. at the meeting of the American Association for the Advancement of Science.

it into a product which ceases to sustain it, but can nourish a lower class of organisms whereby concomitant fermentations arise, whose united effects are frequently such as to completely modify those produced by each separately, and for this reason have the specific actions of some ferments either totally escaped observation or have been misconstrued. Every succeeding year brings additional proof of the important rôle played by these minute organisms, and to such an extent, especially, has this been the case in connection with the rendition of available nitrogen, that there are good reasons to believe that a clearer comprehension of the action of soil ferments will dissipate all the anxiety chemists now entertain as to a gradual diminution of this so essential nutrient.

To Hellriegel, Wilfarth, Wollny, Engelmann, Winograwdski, Warrington, and Heraus can be attributed the most noteworthy experiments in this special line. In order to appreciate the importance of their discoveries, I will, with your kind indulgence, first give a brief historical *résumé* of the study of fermentation. Owing to the extreme age of the use of alcoholic beverages, ferments entering into their production are best known, and this, added to the fact of their being larger and thus permitting of better examination, has been the determining cause of basing investigations and deductions upon their behaviour.

The very fact that the art of cultivating the vine and making wine is attributed by the Egyptians to Osiris, the Greeks to Bacchus, the Israelites to Noah—the brewing of beer to Gambrinus—shows how old these discoveries must have been. The effects of fermentation are sufficiently striking to have called the attention of primitive man to them. The ancient tribes of Asia and Africa understood how to ferment not only grape juice, but also to obtain alcoholic beverages from substances like starch, not directly fermentable. They used soured dough or beer-yeast as leaven for their bread, and knew how to prepare vinegar. The alchemists were wont to clothe their thoughts in such words as to make it difficult for us to decide what precise ideas they attached to the expressions of "Fermentation and Ferments" which are so frequently found in their writings of the thirteenth to the fifteenth century. They even speak of the philosopher's stone as fermenting unlimited quantities of lead and mercury into gold.

In the fifteenth century Basil Valentine in his "Triumphal Car of Antimony" claims that yeast employed in the preparation of beer communicates to the liquor an internal inflammation, thereby causing a purification and separation of the clear parts from those which are troubled, but considers alcohol as already existing in the decoction of germinated barley. In 1648 Van Helmont declared fermentation the cause of all chemical action and spontaneous generation, going so far as to give directions for the production of mice, frogs, eels, &c. He clearly observed the production of a special gas (gas vinorum) during alcoholic fermentation, and stated that something from the ferment passes into the fermentable substance, developing therein like a seed in the soil, thereby producing fermentation.

Willis, an English physician, in 1659 claimed that all functions of life depended upon fermentation, and that diseases were but abnormal fermentations. Both he and Stahl regarded a ferment as a body endowed with a motion peculiar to itself, which it imparts to the fermentable matter. Stahl in 1697 advanced the following theory: "Under the influence of the internal motion excited by the ferment, the heterogeneous particles are separated from each other, recombining so as to form more stable compounds, including the same principles but in different proportions. Putrefaction is but a particular case of fermentation." This theory remained unchallenged eighty years.

Lavoisier, by applying the new methods of organic analysis he had invented, quantitatively ascertained the relations between the fermented matter and the products.

Guy Lussac considered oxygen the sole cause of fermentation, putrefaction, and decay, by transmitting its motion to the ferment and this imparted its motion to the loosely combined fermentable mass.

The present theories of fermentation originated with Schwann and Pasteur. It took a century and a half before the experiments which led up to Schwann's theory found a scientific explanation by the work of this chemist. Leuwenhoeck had in 1680 already noticed that beer yeast was composed of small spheroid globules. Cagniard de Latour declared yeast a plant and the exciter of fermentation.

Schwann's experiments were made to determine the possibility of spontaneous generation. He found that fermentable fluids, when first heated in closed vessels in the presence of oxygen, to the temperature of boiling water would not ferment. This disproved Guy Lussac's theory that oxygen caused fermentation. He next showed that purified air or oxygen passed into a sterilized fermentable fluid did not induce fermentation, but that this set in with the introduction of ordinary air. He concluded from these experiments that the air was not the exciter, but simply the medium containing it, and that in the floating particles of the atmosphere were organisms capable of developing in the fluid, should these be killed by heat, fermentation would not take place. In his examination of these organisms, although his methods were not absolute, his conclusions that alcoholic ferments are of a vegetable nature were correct.

Instead of general acceptance, Schwann's theory received but little recognition.

Schultze's method of first passing the air entering a sterilized fermentable fluid through oil of vitriol, and that of Schroeder and Dusch of filtering it through cotton can be regarded as modifications of Schwann's experiments. All these experiments conclusively show that the particles in the atmosphere are the exciters of fermentation but do not render them visible.

Pasteur, spurred on by the same motive as Schwann—namely, to determine the question of spontaneous generation—made a simple modification of Schroeder and Dusch's experiment, by substituting gun cotton, and achieved most remarkable results. The gun cotton, containing the particles filtered from the air, was dissolved in ether under the microscope, and now for the first time the organisms could be thoroughly examined.

Tyndall's well-known experiments, with the air tight box coated with glycerine, demonstrated that gravity alone can purify the atmosphere so as to debar fermentation from setting in.

Pasteur's theory is that "The chemical act of fermentation is essentially a correlative phenomenon of a vital act beginning and ending with it, there is never an alcoholic fermentation without there being at the same time organization, development, multiplication of globules, or the continued consecutive life of globules already formed."

The following few examples will serve to show that the slightest changes in nutrients may render them worthless as such to certain ferments and available to others. Organic substances showing optical rotation chiefly exist already formed in the animal or vegetable organisms, or they can be easily obtained from such substances formed during vital processes.

When these substances are made synthetically, they are chemically and physically similar to the natural isomers, but usually do not rotate the plane of polarized light. This leads to the belief that these synthetical products consist of active and inactive molecules in such proportions as to neutralize each other.

Pasteur[1] verified his hypothesis by splitting inactive racemic acid into dextro-tartaric acid. Neutral ammonium racemate in a solution to which the proper inorganic salts had been added was fermented by means of *Penicillium glaucum* and beer yeast. The dextro-tartaric acid was consumed and the lævo left.

Lewkowitch[2] took inactive mandelate of ammonia, employing either *Penicillium glaucum* or *Bacterium termo*, in each case at the end of several weeks all the fluids showed more or less dextro rotation. Natural mandelic acid from amygdalin is lævo rotary, therefore here, as in Pasteur's experiment, with racemic acid it showed that the organisms consumed the naturally produced isomer.

Sac. ellipsoideus and split fungi consume the dextro and leave the lævo. The dextro has the same positive as the lævo negative rotation. The melting points and solubility of the right and left are the same, yet we see that these substances, chemically and physically the same, save in their opposite rotatory powers, can serve in one case as nutrients to certain organisms, and the other are worthless as such.

The Micro-Organisms of the Soil (*Sachse*[3]).

These organisms, according to their actions, can be divided into three groups. Those oxidizing constituents of the soil; those reducing or destroying the same; and lastly those by whose activity the soil is enriched. As regards the first group the oxidation can take place in two ways—they can either oxidize by assimilating the organic substances of the soil and re-

[1] Cr xlvi 615, ib 298.
[2] B. xvi 1505, 1569.
[3] *Chem Cent Bl.*, 1889, vol ii. 169, 225.

ducing them to carbonic acid and water, in order to obtain the necessary heat and energy, or they can oxidize by giving off oxygen. The first may be termed intra cellular, and the second extra cellular acting organisms. Amongst the intra cellular we have primarily, the usual ferments of decay, which assimilate and respire at the expense of the carbon compounds. In some cases the organisms have accommodated themselves to seemingly most remarkable materials for respiration, the combustion of which affords the necessary heat. Thus the Iron Bacteria of Winograwdski[1] require ferrous carbonate for their life and development, oxidizing the same to oxide. This can be physiologically interpreted as a respiration process, the protoxide of the respiration material becoming the oxide of respiration product.

The Sulphur Bacteria are equally remarkable. Their cells are distinguishable by containing from time to time granules of amorphous sulphur. These organisms were formerly regarded as causing the formation of sulphuretted hydrogen in sulphur springs.

Winograwdski[2] claims the reverse to be the case. They do not produce sulphuretted hydrogen but consume it, burning it partially first to sulphur, which deposits in the cell water, then completely to sulphuric acid, which passes out and forms sulphates from the carbonates of the surrounding water. When no more carbonates are present, the combustion of sulphur to sulphuric acid ceases. Physiologically this is also a process of respiration directed towards generating heat and energy; sulphuretted hydrogen is the respiration material and sulphuric acid the respiration product.

(Olivier[3] does not agree with Winograwdski and De Rey Pailhade[4] claims the existence of a substance, philothion, in many plants and animal tissues capable of converting sulphur in the cold to sulphuretted hydrogen.)

Certain nitrification ferments can be regarded as intra-cellular. They may take up ammonia and give it off as nitrates, this process ceasing as in the case of the Sulphur Bacteria, when no more carbonates are present.

We now come to the discussion of two ferments, the concomitant actions of which have heretofore caused much confusion. Schloesing and Muntz were the first to observe nitrifying ferments, but to Warrington and Winograwdski belongs the credit of isolating the nitrous from the nitric ferment; furthermore, the striking discovery of a colourless organism, capable of existing and performing its functions, in a medium totally devoid of organic material, and synthetically producing organic bodies independent of sunlight. The importance of this discovery cannot be over-estimated.

Warrington[5] succeeded in obtaining organisms from meadow soil, cultivated in a solution of ammonium chloride and calcium carbonate, which oxidized ammonia to nitrous acid, but had no effect on nitrates. Assimilating the carbon of the carbon dioxide, they require no organic substance for sustenance. They obtain from the oxidation heat of ammonia the necessary energy to dissociate the carbon-dioxide.

Winograwdski[6] obtained the same ferment employing 1 gr. ammonium sulphate, 1 grm. potassium phosphate dissolved in 1 litre Zurich water, to which he added basic magnesium carbonate. After inoculating the sterilized fluid with the nitrifying agent every trace of ammonia disappeared the fifteenth day. He describes this ferment as being an elongated ellipsoid, the smaller diameter 0.9 - 1 Mkr., the larger 1.1 - 1.8 Mkr. The organisms congregate about a piece of carbonate, cover it with their gelatinous mass, and as the carbonate disappears the cells take the shape thereof.

(Although the two investigators do not quite agree as to the morphological attributes of the ferment, Warrington arrived at the same conclusions as Winograwdski.)

Winograwdski[7] has at last succeeded in isolating the ferment which converts the nitrites into nitrates. He employed gelatinous hydrate of silica, impregnated it with a fluid containing the cultivated nitrous ferment. This medium was next inoculated with strongly nitrifying soil from Quito; shortly afterwards two different organisms formed respective colonies, one of these was the one sought for. It was composed of irregularly shaped rods, dissimilar to the nitrous ferment of the same soil. He has since found this ferment in many other soils; it is capable of converting solutions of nitrites into nitrates.

Strange to say the isolated ferment from Quito does not oxidize ammonia; it produced neither nitrites nor nitrates when sowed in ammoniacal fluids, easily nitrified by the nitrous ferment.

In normal soils the nitrate ferment only produces nitrates even in the presence of a large quantity of ammonia, which does not retard the oxidation of the nitrites immediately after their formation.

Muntz[1] claims the existence of an ammoniacal ferment in the soil which converts organic nitrogen into ammonia, preparatory to nitrification.

Extra-Cellular Oxidation

In order to oxidize outside of the organisms, oxygen must be evolved by an assimilation process. Assimilation as an oxidizing cause, for conditions prevailing in the soil, has heretofore received no significance, since the evolution of oxygen, according to the generally accepted theories, depended upon light and chlorophyll, consequently the produced oxidation could only occur on the extreme outer surface. An exception to this heretofore unrestricted rule has been found by Engelmann as well as one by Heraus. According to Engelmann,[2] Bacterium photometricum sharply discriminates between lights of different intensity and wave lengths. The influence of light upon the bacteria is directly proportionate to the intensity. When the intensity is suddenly decreased, the bacteria shoot backwards with opposite rotation (the author calling this a terror motion), consequently a well defined illuminated spot in an otherwise dark drop serves as a trap for these bacteria. They cannot leave, since the terror motion causes them to move back into the illuminated field as soon as they come to the dark outline.

The mobile forms principally congregate in the ultra red rays, *i.e.* physiologically in darkness, and in them as in the visible parts of the spectrum in places closely corresponding to the absorption bands of bacteriopurpurin. This constant ratio between absorption and photokinetic action clearly indicates that the prime effect of light is equivalent to the carbon dioxide dissociating processes of plants containing chlorophyll.

The bacteriopurpurin is a true chromophyll, inasmuch as it converts the actually absorbed energy of light into potential chemical energy. When lights of different colour were employed, the evolution of oxygen increased with the absorption of light by the Purple bacteria. This shows that the power of developing oxygen is not the specific property of a certain colouring matter, as these organisms contain no chlorophyll.

It is not surprising, therefore, that other organisms, either coloured or uncoloured, be found to possess the property of assimilating carbon in the absence of light and evolving oxygen. Such a discovery has now been made—Hueppe[3] substantiating a communication from Heraus that certain colourless bacteria produce from humus and carbonates, in the absence of light, a body closely resembling cellulose. Oxygen is liberated, but remains unobserved, as it is immediately used to oxidize the ammonia to nitric acid.

The next question is: To which extent do the oxidizing organisms partake in the oxidation phenomena actually taking place in the soil? According to E. Wollny[4] the oxidation of carbon-dioxide is almost completely to be attributed to the activity of small organisms, of which Adametz[5] estimated that there are about 500,000 to 1 gr. soil. As in all such experiments, this conclusion is based upon the fact that no evolution of carbon-dioxide takes place, or is forced to a minimum, in a sterilized soil under otherwise favourable conditions.

Liberation of Combined Nitrogen

This may take place during putrefaction under the greatest possible exclusion of oxygen, or during decay in the presence of oxygen. It does not necessarily occur in all cases, or may not be observed owing to a reverse concomitant process, *i.e.*, the fixation of nitrogen. Nitrogen losses can be expected during decay, on account of the action of the produced nitrous acid upon the amidlike dissociation of humous bodies, as well as in the formation of easily dissociable ammonium nitrites. A peculiar case of the disappearance of available nitrogen exists in the reduction of nitrates, as noticed by Springer,[6] Gayon and Dupetit,[7] and Deherain and Marquenne.[8]

Organisms by whose Activity the Soil is Enriched in Nitrogen

A distinction must be drawn between the higher and lower plants It is a well-known fact that most plants cannot assimilate free nitrogen, whereas there are sound reasons for the belief that the legumes are exceptions to this rule The explanation has been sought in the tubercles These tubercles contain a tissue, consisting of thin walled cells filled with an albuminous substance, consequently they are richer in nitrogen than the roots; they have been regarded by some as pathogenic growths, by others as reserve reservoirs for albumin We may now conscientiously assume that these tubercles arise through exterior infection, and that they are not normal growths

Hellriegel and Wilfarth,[1] in their great work, state —"The legumes deport themselves quite differently from the non leguminous plants respecting the assimilation of nitrogen, whereas the latter are totally dependent for their nitrogen needs upon the nitrogen compounds present in the soil, and their development proportional to such disposable supply The legumes have, besides, the soil nitrogen, a second source, from which they can abundantly cover any deficiency existing in the first This second source is free atmospheric nitrogen The legumes attain this power by the co-operation of active living micro-organisms The mere presence of low organisms in the soil does not suffice to make the free nitrogen serviceable, but it is necessary that certain kinds of organisms enter into a symbiotic relationship with the legumes

Lupines acquire nitrogen like the other legumes They starve in a soil free from nitrogen when the presence of low organisms is excluded, but when this is not the case their growth is normal The experiments were carried on in sand containing a suitable nutritive solution Some of the pots were sterilized, to some infusions from soil were added In all and in only those, to which fresh infusions of lupine soil had been added the lupines developed normally bearing the well-known tubercles on their roots, and contained, when harvested, conspicuously larger amounts of nitrogen than the soil and infusion could have given them Wherever the infusion had not been added, or where it had been sterilized at 100 or even 70, the development remained abnormal, the production scant, tubercles remained absent and the harvested plants contained less nitrogen than had been offered them

According to Ward,[2] Breal,[3] and Pradmowski,[4] tubercles will grow on plants free from them when infected with an infusion from tubercles of other plants

Beyerinck[5] has named the infecting organisms, of which there may be many varieties, Bacterium Radicola With the growth of the tubercles the behaviour of the plant towards nitrogen is changed, and the just mentioned independence begins, this has been proved by an almost superabundance of experiments Still the explanation of the manner in which the nitrogen is acquired is not definitely settled The first inference would be that the root-inhabiting bacteria possess the power of assimilating atmospheric nitrogen, and the higher plants as hosts harbouring these bacteria in their roots, use the nitrogen compounds so produced. Thus there would exist a case of symbiosis between Split Fungi and the higher plants We cannot be too slow in accepting this seemingly simple explanation—still the difficulty of a correct interpretation does not alter the fact that the legumes acquire free nitrogen from the atmosphere, and that the refuse of their roots thus enrich the soil They may be called nitrogen collectors in contradistinction to the graminaceous nitrogen consumers

Berthelot[6] has long contended that the free soil can fixate nitrogen, he considers a sandy and clayey nature of the soil essential, it must admit of free access of air, must not be too moist, be rich in potash and poor in nitrogen Gautier and Drouin[7] claim that the presence of humous substances causes increase of nitrogen.

Soils free from organic substances do not fixate nitrogen, or the gain is slight The presence of ferric oxide so long considered capable of fixing nitrogen, has no effect Berthelot, as well as most investigators in this line, attribute the fixation to the activity of nitrogen fixing chlorophyll free bacteria In most cases the amount is much less than that obtained in soils with legumes. No inorganic soil constituents are known to possess the power of fixing nitrogen, and it is questionable whether humous substances can directly do this

In 1881 Atwater claimed that peas during their growth obtained large quantities of nitrogen from the air Atwater[1] and Woods made another series of eighty-nine experiments, the result will be found in their admirable paper in the American Journal I will quote the following "There was in no case any large gain without root tubercles, but with them there was uniformly more or less gain of nitrogen from the air As a rule, the greater the abundance of root tubercles, the larger and more vigorous were the plants, and the greater was the amount of atmospheric nitrogen acquired The connection between the root tubercles and the acquisition of nitrogen, which was first pointed out by Hellriegel, is abundantly confirmed In a number of these experiments, there was a loss of nitrogen instead of a gain The loss occurred where there were no root tubercles, it was especially large with oat and corn plants, and largest where they had the most nitrogen at their disposal in the form of nitrates This loss may probably be due to the decomposition of the seeds and nitrates through the agency of micro organisms In brief, the acquisition of large quantities of atmospheric nitrogen by leguminous plants, which was first demonstrated by experiments here, and has been since confirmed by others is still further confirmed by the experiments herewith reported These experiments in like manner confirm the observation of the connection between root tubercles and the acquisition of nitrogen There is scarcely room for doubt that the free nitrogen of the air is thus acquired by plants"

Chemists, as a rule, hesitate to accept isolated cell life as modifying and conditioning the action of those more differentiated, yet it seems that all circumstances point to the fact that most reactions taking place between nitrogen and plants are influenced by micro organisms

Let us hope that chemistry will, in the near future, score its greatest agricultural triumph, by unveiling the mysteries which still shroud the specific actions of these organisms, thus making it possible to supply the demands of a constantly increasing population

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—A course of instruction (Lectures and Laboratory work) in sciences bearing upon Agriculture will be commenced in Cambridge this term, it will extend over two years and will include the following subjects —Agriculture, Chemistry, elementary and agricultural, Botany, elementary and agricultural, some departments of Physiology and Geology, Agricultural Engineering, Surveying, and Mensuration Arrangements will also be made for instruction in Book-keeping, and in Agricultural Law for those who desire it The subjects taken this term will be Elementary Chemistry, by Prof Liveing, and Elementary Botany, by Mr Seward, of St John's College It is hoped that this course will prove useful to gentlemen intending to farm, or to manage their own land, and to those who are likely to become estate agents Further information may be obtained from Mr H Robinson, at the University Chemical Laboratory, Cambridge Prof. Foster announces a new intermediate course in Physiology, with laboratory work, especially for medical students, to be given by Dr L E. Shore, on Wednesdays and Fridays at ten, during the Michaelmas and Lent terms

Dr Donald Macalister, St John's, has been appointed Assessor to the Regius Professor of Physic.

Mr S F. Dufton has been elected to a Fellowship at Trinity College, and Mr. A Hutchinson of Christ's has been elected to a Fellowship at Pembroke College, in each case for distinction in Chemistry Both gentlemen took first classes in each part of the Natural Sciences Tripos

Mr J Y. Buchanan, F.R.S, University Lecturer in Geography will deliver a course of lectures on Oceanography during the present Term in the New Museums, on Tuesdays at 12 o'clock, commencing on Tuesday, October 18

Mr. W C. D. Whetham, B.A., Fellow of Trinity College, has been appointed Assistant Demonstrator of Physics in the Cavendish Laboratory.

Mr W B Hardy, M A., Junior Demonstrator of Physiology, has been elected to a Drosier Fellowship in Gonville and Caius College.

SOCIETIES AND ACADEMIES

Paris.

Academy of Sciences, October 3.—M. de Lacaze-Duthiers in the chair.—Observations of the new planet Borrelly, made at the observatory of Algiers (equatorial coudé), by MM. Rambaud and Sy, communicated by M. Tisserand.—On considerations of homogeneity in physics, and on a relation between the velocity of propagation of a current and the capacity and coefficient of self induction of the line, by M. C. Clavenad.—On the coexistence of dielectric power and electric conductivity. A claim of priority advanced by Mr. E. Cohn over M. Bouty (see *Wiedemann's Annalen*, vol. xxviii. p. 454).—Comparative evaporation of the solutions of sodium chloride, potassium chloride, and of pure water, by M. Pierre Lesage. Within the limits of the experiments, pure water evaporates more rapidly than solutions of either chloride. The solutions of KCl have, with the same degree of concentration, a greater rate of evaporation than those of NaCl.—On a fossil piece of wood containing fluorine, by M. T. L. Phipson. This was found in the cretaceous sandstone of the Isle of Wight, and analysed thirty years ago. It yielded 32.45 per cent. of phosphoric acid and 3.90 per cent. of fluorine. It had a brown colour and a density of 2.71.—Identity of cascarine and rhamnoxanthine, by the same.—On a respiratory globuline contained in the blood of the chitons, by M. A. B. Griffiths. The yellow blood of the chitons contains a respiratory globuline which contains no metal. It is colourless, and possesses the same properties of oxygenation and deoxygenation as hæmoglobine, chlorocruorine, and other respiratory substances. Its empirical formula is

$$C_{621} H_{814} N_{175} SO_{160}$$

It has been named β-achroglobine, to distinguish it from that of the Patella, which has been called acroglobine.—Influence of the electric light on the structure of herbaceous plants, by M. Gaston Bonnier. After his researches on trees carried out at the electric station of the Paris Central Markets, the writer experimented upon herbaceous plants under similar conditions. The plants were placed at distances varying from 1.5 to 4m. from arc lamps, whose light was kept constant for seven months. The excess of ultraviolet radiation was intercepted by glass shades. Under these circumstances, the majority of plants exhibited intense activity of assimilation. 12 gr. of leaves of *Ranunculus bolbosus* developed 1.05 of oxygen in one hour, the corresponding figure for diffused daylight being 0.52, and for full sunlight in midsummer 3.95. A certain proportion of plants died off, even in intermittent light, especially if no shade was used. Some plants showed an exuberant vegetation, the leaves a deeper green, and the petals more striking colours. Of these, however, the larger number soon began to suffer from excessive assimilation. Some were able to adapt themselves completely, such as bulb plants, grasses raised from seeds, arborescent species, and submerged aquatic plants. The latter also showed no difference in structure, whereas the leaves of crocuses, anemones, and ranunculi became almost unrecognisable owing to anatomical modifications. As a general result, if the continuous electric light through glass produces a great development in an herbaceous plant accompanied by an intense green, the structure of the organs is at first highly differentiated; but if the electric light is intense, and prolonged for several months without change, the new organs formed by the plant, which are able to adapt themselves to this kind of illumination, present remarkable modifications of structure in their various tissues, and are less differentiated, although always rich in chlorophyll. Further, the direct electric light is prejudicial to the normal development of the tissues in virtue of its ultra-violet rays, even at a distance of more than 3m.

Gottingen.

Royal Scientific Society, March to June.—The following scientific papers have appeared in the *Nachrichten*:—

March.—Bürger: Preliminary contributions to a systematic account of the Nemertean fauna of the Gulf of Naples.

April.—Wallach and Marmé: New chemical combinations of vegetable origin.—Hecht: Contributions to geometrical crystallography.—Hurwitz: On the theory of Abelian functions, generalising algebraic functions into multiplier-functions and stating the generalised "Roch" theorem.—Schönflies: Certain rectilinear portions of Riemann surfaces.—Fricke: Discontinuous groups whose substitution-coefficients are integral numbers belonging to a quartic "Korper."—Fricke: Modular correspondences.—Fricke: On the *s* function (2, 3, 7).—Ritter: One-valued automorphic forms of deficiency zero.—Lindemann: Solution of equations by transcendental functions. (Second note. See Roy. Soc. of Gottingen, 1884.)

June.—Hallwachs: Velocity of light in dilute solutions.—Klein: *Real* relations in Abelian functions.—Bodlander: Molecular combinations in solutions.—Traube: The crystal forms of optically uniaxial substances.—Drude: The theories of light tested by practical physics.

FRESNEL'S THEORY OF DOUBLE REFRACTION

The Optical Indicatrix and the Transmission of Light in Crystals By L Fletcher (Oxford University Press Warehouse, 1892)

MR FLETCHER has given us a valuable and most interesting book He has attacked some parts of the theory of double refraction in a manner which is free from many of the objections that may be made to the method more usually adopted, and which has the advantage of closely resembling that by which Fresnel himself made his great discovery

In dealing with this discovery we must carefully bear in mind two facts The result of Fresnel's theory—the determination of the actual form of the wave-surface in a biaxal crystal—is undoubtedly true, the mechanical reasoning on which, in his second memoir on double refraction, he bases that result, is as undoubtedly false In recent times the explanation of the properties of the wave-surface has been usually based on the erroneous mechanical reasoning Mr Fletcher, following Fresnel himself, has shown us how all these properties may be deduced from certain experimental results without the introduction of the false mechanics In one sense this is a backward step, but since the advance had been in the wrong direction, it was necessary to retreat, and though Mr Fletcher's book teaches us nothing new of the mechanism of double refraction, it puts the kinematics of the theory and the geometrical results which it entails on a sure foundation, and this is an achievement for which the author deserves our warmest thanks

The history of the discovery of the law of double refraction, as given in Fresnel's own papers, is of the deepest interest The form of the wave surface, in a uniaxal crystal, a sphere and spheroid, had been discovered by Huyghens Up to the time at which Fresnel wrote it was generally supposed that even in a biaxal crystal one ray obeyed the ordinary law of refraction In 1816 Fresnel and Arago proved that in an isotropic medium the direction of the periodic disturbance to which light is due is transverse to the ray, and from that time Fresnel set himself to investigate the laws of double refraction He soon saw that the reasoning which led him to expect that in a uniaxal crystal the velocity of one wave must be constant could not apply to crystals with two optic axes, and that in such, contrary to the usual belief, there could be no ordinary ray This was announced in June 1820. The first memoir on double refraction, presented to the Academy November 19, 1821, but not printed till 1868, gives a detailed account of the experiments by which this result of his theory was verified, and contains the earliest development of the theory itself. According to Fresnel's views at this time the ether displacement in a crystal was at right angles to the ray—it is noteworthy that the latest development of the mechanical theory leads to this same result—and the velocity of propagation depended on the elasticity of the medium in the direction of displacement. Since, then, for any ray there are two possible velocities there must for that ray be two and only two directions of displacement, the light must be polarized in one of two directions Since, also, the velocities are different in different directions, in Fresnel's view the elasticity corresponding to a given direction of vibration must depend on the direction, and a surface of elasticity can be drawn each radius of which shall be proportional to the elasticity in its own direction When once this surface is known, the rest of the problem can be readily solved Now, in the memoir we are referring to ("Premier Mémoire sur la Double Réfraction, Œuvres Complètes d'Augustin Fresnel," T ii No xxxviii) Fresnel proved, for the case in which the double refraction was not strong, for which therefore the distinction between the ray and the wave normal might be neglected, that if for a uniaxal crystal the surface of elasticity were a spheroid of revolution the wave surface and the laws of double refraction would be those discovered by Huyghens It was an easy step from this to generalize and to suppose that in a biaxal crystal the surface of elasticity might be an ellipsoid, and to examine the results This gave him at once, to the same degree of approximation as in the previous case, the form of the wave surface known by his name and the experimental laws of biaxial refraction discovered by Brewster and by Biot As yet the result was only approximate, worked out more completely the theory can be shown to lead to the same form of the wave surface as that developed by Lord Rayleigh (*Phil. Mag*, June, 1871) Huyghens' laws and those of Biot and Brewster are not accurately obeyed.

But Fresnel's mind moved rapidly, and a week later, November 26, 1821 ("Extrait d'un Mémoire sur la Double Réfraction," Œuvres, Vol ii, No xxxix), he corrected his first results and announced his complete theory The modifications required were not great, in his original theory he had supposed the displacement to be at right angles to the ray, in the final form it is supposed to be at right angles to the wave normal, *i.e*, in the wave front, while the elasticity in any given direction, and therefore the corresponding velocity, is given by the reciprocal of the radius vector of a certain ellipsoid instead of by the radius vector itself. With these modifications the wave surface is accurately Fresnel's surface and the experimental laws of double refraction are accurately obeyed To this ellipsoid (of which the inverse is Fresnel's surface of elasticity) Mr Fletcher has given the name of the "Indicatrix" According to Fresnel's theory the two possible velocities of wave propagation in any direction are the reciprocals of the axes of the section of the indicatrix by the wave front This law has been verified to a high degree of accuracy by direct measurement, and is thus made by Mr. Fletcher the basis of his treatment of the problem. These Memoirs of Fresnel's remained unpublished till 1868 The only printed announcement of the results was a notice in the *Moniteur*, December 12, 1821, with a view of claiming priority for the discovery, and the Report of the Referees, Fourier, Ampère, and Arago, who (August 19, 1822) recommended that it should be printed in full in the "Recueil des Savants Etrangers"

Instead, however, the Second Memoir on Double Refraction (Œuvres, tome ii., No. xlvii) was printed

(tome vii of the Recueil) in 1827, the year of his death, and this is the paper which contains Fresnel's latest developments of his theory In it he suppresses entirely his method of generalization and develops that mechanical theory by which, to quote his biographer Verdet, "he endeavoured to rediscover truths which a profound intuition had first revealed to him" The truths remain, and though Fresnel's methods and their historical development are clearly given in his collected works and in M Verdet's most admirable introduction to them, Mr Fletcher has done good service to science in calling fresh attention to these earlier papers and in making a modification of this method of Fresnel's the foundation of his work

In his note to the first memoir, when discussing the inexact reasoning by which Fresnel afterwards supported his mechanical theory, Verdet writes ("Œuvres de Fresnel," ii, p 327) —

> "Il pouvait sembler singulier que le résultat définitif d'un raisonnement incomplet et inexact en deux points fût une des lois de la nature dont l'expérience a le mieux confirmé la vérité On a vu au contraire que cette loi s'était manifestée à Fresnel comme le résultat d'une généralisation toute semblable aux généralisations qui ont amené la plupart des grandes découvertes Lors qu'il a voulu ensuite se rendre compte de la loi par une théorie mécanique il n'est pas étonnant qu'il ait, peutêtre à son insu, conduit cette théorie vers le but qu'il connaissait d'avance et qu'il ait été déterminé dans le choix des hypothèses auxiliaires moins par leur vraisemblance intrinsèque que par leur accord avec ce qu'il était en droit de considérer comme la vérité"

True though this may be, the fact remains that until Lord Kelvin developed his theory of a contractile ether a few years ago, no one of the distinguished men who have followed in Fresnel's steps had discovered a satisfactory mechanical basis for Fresnel's great generalization But to return to the book before us As has been mentioned, Mr Fletcher's method of development differs somewhat from that indicated by Fresnel He finds it more convenient to work with rays than with wave-normals or wave-fronts, and the construction he adopts is the following —Draw a normal at any point of the ellipsoid of elasticity—the indicatrix in Mr Fletcher's language From the centre of the ellipsoid draw a line perpendicular to this normal, and consider a ray travelling in the direction of this perpendicular Then the reciprocal of the intercept on the normal between the surface and the ray measures the velocity of propagation along the ray, and the plane of polarization of the ray touches the indicatrix at the point at which the normal is drawn According to Fresnel's theory the radius vector drawn from the centre to this point is the direction of vibration in the ray, while according to the most recent modification of the theory, the motion takes place along the normal itself From this simple construction the form of the wave-surface and all the known laws of the propagation of light in crystals are deduced in a strict and skilful manner At the same time, while giving Mr Fletcher the fullest credit for his originality, we are at times inclined to wish he had adhered more closely to Fresnel's method He admits of course himself that a single ray cannot be propagated through the ether We may hope that some of those who read his book will go on to study the mechanical theory of double refraction Then they must deal with waves and not with rays, and they would find it an advantage to have had the one idea to guide them throughout. Again, the new method leads to a multiplicity of names for one and the same thing, and this is a disadvantage We have ray-surface used for wave-surface, although the two are identical, nor is it easy at first to recognize the optic bi-normals and the optic bi-radials as the optic axes and the lines of single ray velocity respectively, but these are small points when compared with the main object of the book, which well deserves attention and careful study The last chapter deals with the problem in a more general way, but space forbids us to follow Mr Fletcher into the questions he there raises, it must suffice to call the reader's attention to it, and especially to the fallacy discussed in Section 17

R I G

THE PROGRESS OF HORTICULTURE

Contributions to Horticultural Literature By William Paul, F L S (Waltham Cross, Herts W Paul and Son, 1892)

For about half a century Mr Paul has been labouring at the work of horticulture alike in the garden and at the desk As a business man he has not confined himself simply to commercial routine As an observer and an experimenter he has not been hedged in by the dogmas and prejudices of any particular school of science, and as a writer his aim has always been to record truthfully and instruct faithfully It is a matter of congratulation, therefore, that the author should have gathered together in a convenient form some records of a lifetime's work

Certain portions we should have eliminated as of past or of personal interest only, certain others as of relatively minor importance, but Mr Paul is addressing a mixed audience with varied sympathies and interests, and it may be that the paragraphs we should mark for deletion would be those which others would best care to preserve

Mr Paul groups his writings, as here collected, under the three heads of (1) roses, (2) trees and plants, and (3) fruit culture and miscellanea They would fall equally well under other categories, such as the commercial and practical, the æsthetic and the biological In this notice we must confine ourselves to Mr Paul's writings as a naturalist Such, however, is the interdependence among various branches of inquiry, that it is almost impossible, in this connection to isolate any special subject, even if it were desirable to do so From this point of view Mr Paul's book is, though undesignedly, an apt representation of the present condition of horticulture On the one hand, the relations of that art to the perception of and to the canons of beauty are obvious Equally clear are its bearings on routine practice. On the other hand, its connection with biological science, in spite of the teaching and example of Darwin, is not yet adequately recognized, nor has the statesman as yet grasped the truth that progress in agriculture must follow to a large extent on the lines familiar to horticulturists Of the many remedies proposed to mitigate and clear away the depression under which agriculture is suffering, none is more likely to be serviceable than the adoption, so far as

circumstances permit, of the principles and practice of the progressive gardener This is very obvious to those conversant with the state of commercial horticulture, as contrasted with the condition of the corresponding department of agriculture, and it will be brought home to the thoughtful reader by the perusal of some of Mr Paul's pages It is interesting, too, to see that matters at which some minds would still be inclined to scoff as unpractical, or which they would regard as mere means of affording agreeable recreation, are the very departments in which the greatest practical successes have been achieved in the past, and which are of the best augury for progress in the future

Biologically speaking, Mr Paul has been not only a keen observer but a careful experimenter on a very large scale, and over a very long period It is true his experiments have not been and could not have been made with the exact accuracy which we expect in the laboratory, but they have been made under conditions far more akin to those which occur in nature Moreover, they have been made, although with a definite aim, yet without reference to any particular theory The reader will accordingly find in these pages records of work and inferences from carefully planned experiments directly bearing on many subjects now attracting the attention of naturalists, such as hereditary transmission, variation from seed or from bud, selection, fixation, close fertilization, and the various degrees of cross-impregnation Incidentally these subjects receive illustration in many chapters of Mr Paul's book, but the address on "The Improvement of Plants," which was read in 1869 before the provincial meeting of the Royal Horticultural Society at Manchester, contains a summary of Mr Paul's views on these subjects, which we strongly commend alike to the notice of naturalists and of agriculturists

It is very interesting to compare what he says about selection and variation in plants, such as the Camellia, the Chinese Primrose, or the Hollyhock, which are the offspring of what we regard as pure species, with the corresponding processes in the Rose, the Pelargonium, or the Chrysanthemum, which are veritable mongrels In this connection we may in passing allude to the power which the gardener has, of course within limitations, of creating new forms The orchid cultivator, for example, inferred parentage of certain hybrids met with in a wild state, but he has since proved the correctness of his inference by actually producing in his orchid-house many of the same forms that occur in the forests of the tropics Another very striking case (not specially alluded to by Mr Paul) is the production and development of what are known as tuberous Begonias These have been evolved by the art and patience of the gardener within the last quarter of a century from repeated crossing between certain Andean species of Begonia and their descendants The result is the establishment of a race so totally distinct from anything yet known in nature as would justify a systematic botanist in forming a separate genus for their reception Many an accepted genus is based upon less important points of distinction than those which characterize the tuberous Begonias, and which, indeed, have been gathered together by Fournier under the genus Lemoinea The degree of permanence of this artificially formed genus is, of course, unknown, but we do know already that the peculiarities are reproduced from seed, and that each year the plants are, as the gardeners say, becoming more "fixed" We have alluded to these as illustrations of the kind of work upon which Mr Paul has been engaged for half a century They may be taken as examples of the material he has gathered together in this book, which is not merely presented for the delectation of the ordinary lover of flowers or the profit of trading horticulturists, but is also calculated to increase the productive resources of the country, as well as to forward the progressive development of our knowledge of the natural history of plants

As a further illustration of Mr Paul's method we cite in conclusion a passage which will, we think, justify us for recommending to scientific readers the perusal of a book which they might be disposed, from its title, to think had little in it to interest them "My experience in selecting, hybridizing, and cross-breeding tells me that he who is seeking to improve any class of plants should watch narrowly and seize with alacrity any deviation from the fixed character, and the wider the deviation the greater are the chances of an important issue However unpromising in appearance at the outset, he knows not what issues may lie concealed in a variation, sport, hybrid, or cross-bred, or what the ground newly broken is capable of yielding under careful and assiduous cultivation If we would succeed in this field we must observe, and think, and work Observation and experiment are the only true sources of knowledge in nature and while observing and experimenting we should above all things guard against prejudices"

MAXWELL T MASTERS

LIFE IN MOTION

Life in Motion or, Muscle and Nerve By John Gray McKendrick, M D, F R S (Adam and Charles Black, 1892)

UNDER this title Prof McKendrick gives us the gist of six lectures delivered by him during last Christmas holidays to a juvenile audience at the Royal Institution of Great Britain, and, judging from this little work, it is evident that no pains was spared by him to render these lectures as instructive and interesting as abundant illustrations and experiments could make them. In presenting these lectures to the public in book form he places us under an obligation gratefully to be acknowledged for professional physiologists stand alone amongst their colleagues in other departments of science in their disdain of any attempt at the production of attractive and simple scientific literature In very pleasing sympathetic style the reader is introduced to the world of motion and to the special motions of the living muscle He is shown how the movements of a muscle are recorded by the physiologist, and the apparatus used for its stimulation Artificial tetanus is described, the muscle sound and its elasticity referred to, and a perhaps too short description given of amœboid and ciliary motion The physiology of the nerve is then discussed, and the production of heat in muscle In the fifth lecture is a short account of the sources of muscular energy, a comparison is drawn between a muscle and the steam engine, and a comparatively detailed account of muscle fatigue is given

The sixth and final lecture deals with the electrical phenomena of muscle and with a very curious group of fishes termed "electrical"

The arrangement of the book is excellent, yet we are inclined to think that it shares with many other works on physiology one common fault What we all want to know more about is the life and activity of the organism, and the physiologist very rightly spends much of his time in experimenting in every conceivable way, and generally with isolated parts of the organism His apparatus is often of the most varied and intricate kind, and his experiments yield him definite results Many of these results, however, are at present of little value in shedding light on physiological processes, and should not, we think, obtain the prominent position they now occupy in the text-books To take an example, the experiment to demonstrate the muscle curve, in which the muscle is isolated and stimulated electrically, is one of the stock experiments minutely described in every text book In this experiment the muscle is separated from its antagonistic muscles, stimulated in quite an unnatural way, and the result of the experiment is totally different from what takes place in a contracting limb It is certain that in nearly every text-book the reader will find that from this and similar experiments he is apt to obtain incorrect and misleading ideas He no doubt learns something regarding very interesting electrical machinery, but very little physiology Of recent years far more attention has been bestowed upon the movements of muscles in the limbs, and comparative physiology is at last asserting its influence It is to be hoped that when this knowledge finds a more prominent place in text-book literature, "muscle and nerve physiology," in the proper sense of the term, will be more satisfactorily taught

Returning to what more exclusively concerns Prof McKendrick's book, we may point out a slip on page 81, where it would appear that the muscle sound corresponds in pitch to the fundamental tone of a body vibrating 19 5 times a second, instead of to one vibrating at twice that rate, and that Prof McKendrick does not interpret this sound on the lines followed by Helmholtz and others On page 91 the modern view of a "cell" is represented in a drawing, and the nucleus has inadvertently been omitted On page 31 a long and short circuiting key is represented, while a simple key is described in the accompanying text These, however, are but trivial faults to find in an excellent little work, which is most admirably got up and beautifully illustrated by nearly one hundred excellent figures.

The reader will, we think, obtain a good insight into a department of physiology, and will be stimulated to further research in the literature of this interesting subject.

PLUMBING

Principles and Practice of Plumbing By S Stevens Hellyer (London George Bell and Sons, 1891)

THOSE who are acquainted with Mr Hellyer's larger book on domestic Sanitation, "Dulce Domum," will not find much new matter in the present volume, but the subjects are treated less discursively, and are fairly well brought down to date

There is no trade which has been more discussed in recent years than that of plumbing, and if plumbers are not impressed with a sense of their responsibilities, it is certainly not the fault of the architects and engineers who employ them The manual skill necessary to perform the most ordinary operations is in itself so difficult that many workmen fail to acquire it, and, on the other hand, many experts in the details of the craft are never properly educated in the principles of sanitation which are necessary to make their work effectual from a sanitary standpoint It is the combination of both kinds of knowledge in the writer which makes Mr Hellyer's books of exceptional value It matters little whether it is an architect on one hand, or a working plumber on the other, who studies them, because they are of equal value and of equal interest to both The present handbook is specially valuable in these respects because most of the information upon matters of practical workmanship is given concurrently with the reasons which should control the details and the principles which should be in evidence when the work is finished

No one unacquainted with the practical difficulties which frequently crop up in sanitary practice can realise how much knowledge and experience is necessary to overcome them Houses in London often present the most puzzling problems, and an intimate acquaintance not only with the principles and practice of the subject, but also with all the most recent appliances, is required for their successful solution The ventilation of all the different parts of a complicated drainage system, including that which is necessary to prevent the syphonage of traps, sometimes requires an amount of thought and attention which a layman would think was uncalled for in the face of its apparent simplicity It is no wonder that there are frequently failures to meet the highest standard of excellence, especially when incompetent persons are employed to design and superintend the necessary operations On the other hand, there are thousands of houses in London in which no such difficulties occur, and in which the drainage and plumbing arrangements ought not only to be extremely simple in themselves, but intelligible to the ordinary householder When such cases are entrusted to a builder, or an intelligent plumber, the first requisite is the manual skill required to carry out the various details, and this must be acquired by the workman through apprenticeship, or from his having acted as the assistant or "mate" of a journeyman for several years The next requisite is that he should have a clear knowledge of what he is going to do and why he does it This may be acquired to a great extent from his being familiar, in his capacity as a workman, with the designs of an architect or engineer under whose directions he has been employed, and it is to such men that Mr Hellyer's text-book should be specially valuable By studying its pages he will avoid many mistakes He will know what sort of joint to make, what kind of trap to avoid, how to secure the traps from syphonage, and how generally to complete his work so as to pass the latest standards of excellence We can equally recommend it as a text-book for architects

who, although they are unable to acquire any technical skill in carrying out the operations themselves, should have, nevertheless, an intimate knowledge of the principles which they ought to embody.

We think that more space should have been devoted to that portion of the book which deals with drainage proper. While nearly 100 pages are given to lead-laying and the jointing and bending of pipes, only about twenty pages are devoted to house drains, and a great part of this is occupied with illustrations of appliances. Not more than one or two pages are given to the subject of cast-iron drains, although they are strongly recommended, and the subject is a very important one. We trust, however, that the author will remedy these deficiencies in the future editions which will doubtless be required to supply the demand for his excellent text-book.

OUR BOOK SHELF

A Lecture Course of Elementary Chemistry. By H. T. Lilley, M.A. (London: Simpkin, Marshall, Hamilton, Kent and Co., 1892.)

THE abrupt use of chemical terms, and the condensed style adopted by the author in this book, make it evident that it is not specially designed to smooth down the difficulties which confront the unaided learner who approaches chemistry for the first time. It seems rather to be fitted to replace the notes which might be taken on a course of lecture instruction. Regarded in this light it is a useful volume, the knowledge it contains being, in the main, sound and to the point.

It deals with the metals as well as with the non metals, and dovetailed with the ordinary chemical information are many instances that the author has tried to keep pace with current work, and has attempted to give the student all the important points to be noted in a fairly complete course of elementary chemistry.

A short series of exercises chiefly in chemical arithmetic are given at the end of the book, and a table of contents and an index are supplied.

It would be advisable on p. 53 to say that ordinary sulphur crystallises in the rhombic system. To speak of the crystalline form as an octohedron tends to create an impression common among students, that ordinary sulphur belongs to the cubic system. Fluorine was not made by the electrolysis of liquefied hydrofluoric acid, but of a solution of potassium fluoride in the acid; the pure acid is a non-electrolyte.

It is hardly correct to state that calcium sulphate and hydroxide are the only known examples of solids less soluble in hot than in cold water; calcium isobutyrate and one of the thorium sulphates are additional instances. On p. 98 the flame colorations of potassium and sodium are confused, and brass seems to be omitted in treating of the alloys of copper and zinc. J. W. R.

Longmans' School Geography for North America. By George G. Chisholm and C. H. Leete. (New York: Longmans, Green, and Co.)

IF Mr. Chisholm's well-known geographical text-book was to be extensively used in the United States, it was inevitable that it should be altered in a way which would adapt it to the special needs of American schools. The task was undertaken by Mr. Leete, and he has accomplished it with much skill and judgment. The parts he has rewritten are those relating to America in general, North America, and the United States. To these he gives a prominence which was not necessary or desirable for European students of geography, but which is no doubt essential for learners on the other side of the Atlantic. The plan of Mr. Chisholm's book and the spirit of its execution have both been maintained, and the work ought now to be quite as useful in the New World as it has already been in the Old.

Garden Design and Architects' Gardens. By W. Robinson, F.L.S. (London: John Murray, 1892.)

THE author of this book is firmly convinced that to clip and align trees in order that they may "harmonise" with architecture is "barbarous, needless, and inartistic." He is in love with Nature's methods, and would give them in gardens much freer scope than is accorded to them by persons who like best a certain trimness and formality. It is to be regretted, perhaps, that Mr. Robinson deals with the subject in so polemical a temper, but the cause for which he contends is good, and he does excellent service by bringing out prominently what has always been the essential principle of the best and most characteristic kind of English landscape gardening. The value of the essay is greatly increased by a number of well-selected illustrations.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Alleged "Aggressive Mimicry" of *Volucellæ*

IN the course of a review (NATURE, October 6, 1892, p. 535) of a book, "Animal Coloration," by Mr. Beddard, Mr. Poulton takes occasion to refer to a theory professing to elucidate the resemblance of *Volucellæ* to humble bees, &c. This reference is occasioned by the suggestion of a counter-hypothesis by Mr. Beddard. The view adopted by Mr. Poulton ("Colours of Animals," 1890, p. 267) is that proposed by Kirby and Spence, and subsequently alluded to by Kunckel d'Herculais ("Organ. et Devel. des Volucelles," Paris, 1875) and others; but as Mr. Poulton makes no reference to these authorities he may be assumed to accept the full responsibility. In the place named he says:—"The boldness of these enemies sometimes depends on the perfection of their disguise. Thus the larvæ of flies of the genus *Volucella* live upon the larvæ of bees and wasps. *Volucella bombylans* occurs in two varieties, which prey upon the humble bees *Bombus muscorum* and *B. lapidarius*, and are respectively like these Hymenoptera. The resemblance is very perfect, and the flies enter the nests to lay their eggs." Mr. Beddard (*l. c.*, p. 225) criticizes the view that the fly resembles the bee that it may with impunity enter the nest, and proposes to look on the presence of the fly's larvæ in the bees' nests as akin to the presence of supposed "pets" in the nests of ants. As Poulton points out, this suggestion leaves the original difficulty of the likeness of the fly to the bee untouched.

Having little interest in either of these speculations, which seem fantastic and premature, it is with reluctance that I take part in the discussion. The case, however, of *V. bombylans* is not only interesting as a striking, and to us in England a most accessible instance of the phenomenon of Mimicry, but as an example of Variation it is almost unique among animals, while among plants perhaps it is paralleled only by Darwin's famous case of the peach and the nectarine. It is besides a case well suited for experiment and close observation. The nests of surface building bees may towards evening be lifted bodily, bees, *Volucellæ*, and all, with a spit of earth, and transferred to a box. This may be taken home and set next morning on a window sill, when on opening the box the bees will go on with their work for the rest of the summer. If any one seeks an opportunity of honestly trying to get to the bottom of a case of Mimicry, instead of speculating about it at large, he can scarcely find a better case than this. The need for such observations is great, for the account confidently given by Poulton, though according well with his hypotheses, accords with the truth less well.

In these circumstances it may not be out of place to give a brief statement of the facts as they were established by entomologists long ago. The *Volucellæ* are a small group of flies, con-

taining four British species (Verrall, "Cat Brit Dipt," 1888), of these most if not all resemble various Hymenoptera The commonest and most remarkable is *V bombylans*, which may be seen in any English hedgerow on a sunny day in early summer This fly exhibits the rare condition of existing in two distinct forms in both sexes The one form is black with a red-tail, in no small degree resembling a small worker of a red-tailed humble-bee such as *B lapidarius* L or *B Derhamellus* Kirb The other form has a yellow border to the thorax, yellow hairs on the antero-lateral parts of the abdomen, and a grey tail, to an equal degree resembling a small worker of one of the several yellow banded humble bees, *e g B hortorum* L, *B terrestris* L, or *B Scrimshiranus* Kirb Both varieties occur in both sexes and are about equally common The problem of the evolution of these distinct forms is thus one of the most complex Some may ask, If the varieties are thus distinct, how are they known to be one species? The evidence of this is (1) that no point of structure can be found to differentiate them, (2) that males of the one variety have been seen coupled with females of the other and *vice versa* (Macquart, "Suites à Buff," p 479, Zeller, *Stet ent Ztg*, 1842, p 66), and lastly (3) that intermediate forms have been found as rarities (Erichson, *Stet ent Ztg*, 1842, p 115) This evidence may not satisfy all, but as regards Mr Poulton the identity of the two as one species is not in dispute, for he admits this

But though the likeness of *V bombylans* L and its var *mystacea* L. (= *plumata* de Geer) to the red tailed humble bees and to the yellow banded humble-bees respectively, is really close, neither these forms nor the less common var *haemorrhoidalis* Zt present any special likeness to *B muscorum* L, which has a bright brown thorax and a grey abdomen It is true that Kunckel has spoken of a resemblance between the var *mystacea* and *B muscorum*, but it is hard to see upon what ground, for indeed it is much as if one were to liken a tabby cat to a fox As Kunckel himself says, the great resemblance of the fly is to the yellow banded *B hortorum*

To return to Mr Poulton's statement, he says that the two varieties prey upon "*Bombus muscorum* and *B lapidarius*, and are respectively like these Hymenoptera" These words contain an ambiguity which I cannot believe intentional But supposing for a moment that one of the varieties *were* like *B muscorum* (which it is not), the sentence must be taken to mean that each variety preys upon the species of bee which it most resembles, the red-tailed variety on the red tailed bee and the yellow variety on the other This is indeed demanded by the hypothesis of "Aggressive Mimicry" In this form the statement is often made, though I never met it elsewhere in print I invite Mr Poulton to produce observations in support of that statement If he will establish it he will do a useful work When this statement was written I must believe that Mr Poulton had not read the several authorities on the subject, many of whom relate how both varieties have been reared from the nests of each type of bee, both from the red tailed and from the yellow-banded (Kunckel, p 58, Drewsen, *Stet ent Ztg*, 1847, p 211, F Boie, Kroyer's "Naturh. Tids," 1838, p 237) It is still possible that both varieties are born of one mother, and it is possible, too, that each female does her best to choose the nest of a bee like herself, but in support of this hypothesis I know no evidence, and indeed Kunckel (p 58), after considering this possibility, gives it as his opinion that probably the varieties of *V bombylans* lay indifferently in the nests of all *Bombi* From the omission of these facts, which to an appreciation of the evidence are vital, we should infer that Mr Poulton was not acquainted with Kunckel's work, were it not that he repeats Kunckel's selection of *B. muscorum* as a form resembled by one of the two varieties

But though Mr Poulton is wrong in saying that either variety specially resembles *B muscorum*, he is right in saying that *V. bombylans* preys on this bee's nests, for *both* varieties have been bred from them, even from the same nest (Kunckel, p. 58) In my rooms at this moment are several nests of *B muscorum*, each containing many larvæ of *V bombylans*, resting for the winter, to emerge in summer, as I hope

There is then evidence that the two varieties, though they may breed together, yet remain substantially distinct, and that though they respectively resemble different species of bees, they are both found together, not only in nests of bees which they resemble, but also, and in my own experience, more abundantly, in the nests of another bee which they do not resemble.

Mr Poulton further omits to mention that *V pellucens*, though in nowise resembling the common wasp, yet lives in its nests, together with *V inanis* which does resemble a wasp, and *V zonaria* which is like a hornet (Kunckel, pp 54 and 55) This fact also I commend to Mr Poulton's ingenuity

The publication of statements like this of Mr Poulton's, omitting most salient facts—facts, besides, which, though adverse to his speculations, add a ten fold interest to the subject—is surely unfortunate It may be replied that Mr Poulton's book is of a popular character and does not aim at the completeness of scientific work, but in making choice of evidence, even for popular exposition, it is well to remember that the value of facts is not to be measured by the ease with which they may be momentarily fitted to the sustenance of a facile hypothesis WILLIAM BATESON

St John's College, Cambridge, October 9

Induction and Deduction

MISS JONES agitates a question that ought not to settle down without having caused that discussion which its propounding is fit to awaken

This discussion does not, however, relate to the mutual relations of Induction and Deduction—at least, not as the main topic thereof It relates to the fragmentary condition of that which is usually referred to and accepted as logic We are so apt to take it for granted that our so called logic is tolerably competent and complete as an account of human reasoning in general, that it is of great utility when some one—as Miss Jones does now—raises a question that is adapted to direct our reflections towards some one of the several, perhaps many, gaps that exist in that most important, but too often not understood and misunderstood, branch of science It is with this specially in view that I have ventured to write this

In geometry nothing is more usual than to draw a universal conclusion from a case that, to all ordinary ways of apprehension, seems to be a single instance Indeed, this is one of the cardinal features of geometrical reasoning Perhaps we might well say that it is the most characteristic feature It is this feature that the question that Miss Jones agitates ought to call into prominent notice

She selects for her purpose the case of the isosceles triangle, and asks, How, from premising that the angles at the base of an (one) isosceles triangle are equal to each other, are we logically warranted in concluding that that same equality is true of all isosceles triangles?

That we do thus conclude is known to all, as is also the truth that such a conclusion is a typical one in geometry Nor have we, nor can we have, the least misgiving as to the rigorous validity of such conclusions

It would be a digression for me to point out here the essential characteristics of that form of reasoning which, properly speaking, is induction It is sufficient for my present purpose to remark that true induction is utterly unable to yield us any conclusion that is more than *probable and approximate*

From these characteristics alone we may know that our geometrical conclusions in view are *not*, as Miss Jones takes them to be, inductive conclusions

But since our geometrical conclusions are natural and valid, the question still remains, What sort of conclusions are they?

If we propose to call them deductive conclusions, then, when we revert to the array of syllogisms, categorical, hypothetical, disjunctive, dilemmatic, &c, we find none of them, nor any combination of them, that can by any means be made applicable We have to get not merely from an apparently particular but from an apparently absolutely singular proposition to a universal one To do this deductively, the body of doctrines and canons, that is usually called logic, confesses itself wholly unable It lays down as one of its cardinal rules, one that it declares is "founded upon the Laws of Thought," that if any premise is particular, then only a particular conclusion can be drawn

Nevertheless, I am going to submit that the reasoning under discussion is a true instance, not of induction, but of deduction. I submit that the reasoning that we do actually follow is that which may be formulated thus:—

This isosceles triangle is ANY *isosceles triangle*

The angles at the base of this isosceles triangle are equal to

each other Therefore, the angles at the base of any (or every or all) isosceles triangle are equal to each other

In order to make the nature of this reasoning plainer, I will put the same in symbols

Put X = the isosceles triangle in general,
Z = this particular isosceles triangle,
a = angles at the base,
e = equal to each other

Then our reasoning will appear thus —

Z is X,
a of Z is e
a of X is e

This looks very much as though we had in hand a case of the logic of relatives

We will all recollect the challenge of De Morgan —"If any one will by ordinary syllogism prove that because every man is an animal, therefore every head of a man is a head of an animal, I shall be ready——to set him another question" This would be in symbols—

All M is A,
h of M is h of A

Our case, according to this sort of formulation, would appear—

Z is any X,
a of Z is a of X,
a of Z is e,
a of X is e

The distinguishing characteristic of our case as compared with the case put by De Morgan resides in the different natures of the two propositions—

All M is A,
and Z is any X

The former is the usual universal categorical affirmative proposition of ordinary logic The latter is a sort of universal categorical affirmative proposition that certainly exists and is important, but which has not yet been recognized, unless it may be by the quantifiers of the predicate in their proposition—

All A is all B

It implies rigorously that not only

Z is any X,
but that Z is every X,
Z is all X,
any (or every or all) X is Z
„ („ „) not X is not Z
„ („ „) „ Z „ X
any X is every Z
every X is any Z
every not X is any not Z
any „ „ „
&c, &c

In truth, to a superficial notice, it may easily seem to confuse the most important logical distinctions But this is only because we are so used to identifying logic in general with the logic of extension It is the logic of extension, or in other words, metric logic, that has been persistently tendered to us as the only logic worthy of study, if not indeed as the only logic practicable or perhaps possible Yet we can now, I think, see that geometry at least makes great use of a logic that is not the logic of extension, and that the existence of geometry is an earnest that that other logic may be developed and formulated, if not completely at least to some very useful extent

The proposition,

Z is any X,

is, as I conceive, a proposition of the logic of intension It applies not to things, or to concepts in connection with things, but to pure abstract concepts like geometrical figures, whose marks are exhaustively specified, or, if any are not specified, the same depend upon and are implied by those that are specified

One point more remains to be explained

We must not from the recognition that Z is any X, and the rigorously following proposition that whatever is true of either X or Z is true of the other, conclude that these propositions should if valid hold for marks that are accidental to Z, or to any single instance of X. If we fail to keep clearly in mind the intensive scope of our propositions, we may discredit them, or one of them, by observing that although we have laid down that whatever is true of Z is true of any X, yet nevertheless it does not follow that Z is any X, as regards say the size of Z or any single instance of X Size may not be any necessary mark of either, and if so it is for all logical purposes impertinent to the propositions in question, and must be altogether ignored

I will conclude by saying that the inference actually made in the case put by Miss Jones is a deduction, because it necessarily follows from the premises laid down Logic has no connection with the truth of premises, it only says what certain propositions entail If in an intensive sense this isosceles triangle is any isosceles triangle, then any isosceles triangle is this isosceles triangle, and every isosceles triangle is this isosceles triangle, and all isosceles triangles are this isosceles triangle, and if the angles at the base of this isosceles triangle are equal to each other, it follows necessarily that the angles at the base of all isosceles triangles are equal to each other

Chicago, August 16 FRANCIS C RUSSELL

BY the courtesy of the Editor of NATURE I have been allowed to read Mr Francis C Russell's very interesting remarks with reference to my note on "Induction and Deduction" in NATURE of July 28 (p 293)

I agree with Mr Russell as to the validity and certainty of an inference from equality of angles in *one* isosceles triangle to equality of angles in *all* isosceles triangles But while I regard this inference as a "true induction" because it is an inference to a general proposition on the strength of a particular instance, Mr Russell denies that it is an induction because he holds that induction can give only approximate and probable conclusions, and considers that the certainty which he allows to belong to the geometrical conclusion in question is due to the fact that the inference is *not* from a particular instance, but is really and truly *from* universal *to* universal—the one isosceles triangle from which the argument starts being a kind of "pure abstract concept," so that we can say—

This one isosceles triangle is *any* isosceles triangle, therefore *every* iso celes triangle is *this* isosceles triangle, &c

This appears to me to be entirely inadmissible How can *this* triangle *BE that* and *the other* triangle? To say that it is, is to lose sight of the distinction between *identity of individuality*, and *similarity of characteristics* And that the assertion (*this* triangle is *every* triangle) is untenable appears also from Mr Russell's own admission further on, when he says that "we must not, from the recognition that Z is any X, and the rigorously following proposition, that *whatever* is true of X or Z is true of the other, conclude that these propositions should, if valid, hold for marks that are accidental to Z or to any single instance of X" If Z *is* any X, how can any X have marks which Z has not, or Z have marks which any X has not? We cannot get out of the difficulty by reference to extension and intension, for this reason, that every categorical proposition, to be significant, must be read both in "intension" and in "extension"—that is, affirmatives must be understood as asserting identity of extension (application) in diversity of intension (signification), while negatives *deny* identity "This isosceles triangle is *any* isosceles triangle" can have a useful signification only if it is interpreted to mean—

This triangle [not *is* but] *is similar* (in so far as isosceles) *to* any isosceles triangle—that is, all are *similar* in respect of the characteristics which are inseparable from equality of sides Hence (as I said in my letter, July 28) "in all cases equality of angles at the base is inseparable from equality of sides"

I am not clear what precise meaning can be attached to the expression "pure abstract concept," still less how a geometrical *figure* can be an abstract concept I am, moreover, disappointed that Mr Russell makes no examination whatever of my own attempt to formulate the process from Particular to General

With reference to Mr Russell's symbolical argument—

Z is X,
a of Z is e,
a of X is e,

I think that it may be logically described as a process either (1) of Substitution (Jevons)—a kind of Immediate Inference dependent on identity of application—thus —

Z is X;
∴ X may be substituted for Z

In a of Z is e
substitute X for Z,
and we have a of X is e

Or (2) a combination of what Jevons calls Immediate Inference by Complex Conception (which I should like to class with some other Immediate Inferences as Extraversion, which is largely used in mathematics) and Mediate Inference, thus—

Z is X (a)
∴ a of Z is a of X ∴ (b)
But a of Z is e (c)
∴ a of X is e (d)

(b) is Inference by Complex Conception from (a), (b) and (c) are the premisses which give (d) as their (syllogistic) conclusion.

Cambridge, October 11. E. E. CONSTANCE JONES.

The Temperature of the Human Body

MR. CUMMING'S second or "physical" query will, I think, require no answer if his first or "physiological" question is replied to. If an isolated muscle from which evaporation was prevented could go on working in a heat enclosure, and always remain at a lower temperature than the enclosure (which it could only do by transferring heat from itself to its surroundings), we should have to ask in good earnest how this was consistent with the Second Law of Thermodynamics. We are quite certain, however, that the temperature of the working muscle would always, when a steady state of things had been reached, be above that of the enclosure.

The temperature of an isolated muscle during activity (assuming that it could be kept alive and evaporation prevented) would, of course, not only be very much higher "at the equator" than "at the pole," but also somewhat above that of the surrounding bodies in either latitude. The intact homoiothermal animal, even when the temperature of the air is greater than that of its blood, is on the whole, within the limits which can be borne, always losing more heat to its surroundings than it receives from them. For heat is still becoming latent at the evaporating surfaces of the body, the skin and the respiratory mucous membrane, even when the balance of gain and loss by radiation, &c., is telling the other way, and, indeed, in general more evaporation than usual is going on when this is the case. The temperature of these surfaces is always kept below that of the blood which comes to them. The blood, therefore, always loses heat here, and gains it from the muscles, which accordingly transfer heat to a medium colder than themselves, even when the external temperature is higher than that of either.

If, of two similar and similarly situated men, A and B (I ask pardon for degrading an austere geometrical phrase to such loose and vulgar application), exposed to the same high temperature (above that of the blood, say), A sweats little and B much, while the blood-temperature of both remains constant, A must either produce less heat than B or lose more in other ways than evaporation of sweat. He may produce less either because he works less than B, or because even at rest his metabolism is not so active. Or an extra loss of water-vapour from the lungs may make up for the diminished loss from the skin. For example, in the dog, which has but few sweat-glands, nearly the whole of the evaporation takes place in the respiratory tract. Of course much water is evaporated from the skin which never appears as visible sweat, and it is possible that some persons give off a greater proportion of the total perspiration in this way than others do, the quiet steady sweater, if one may be allowed the expression, getting through as much work on the whole as the steaming paroxysmal kind of fellow who breaks out into dewdrops on the smallest provocation. But it should be clearly recognized that an air temperature equal to or above that of the blood is occasional, and not permanent in any latitude, and that men, and even animals, adopt expedients to avoid such extremes and to tide them over.

Any good recent text-book of physiology will give the information asked for as to what is known of the mechanism by which the temperature of warm-blooded animals is kept approximately constant. It is too wide a subject to be entered into here. In man the regulation of the heat loss seems to be far more important than any regulation of the production of heat. The former is, of course, largely voluntary, but the quantity of blood going through the skin, an important factor in more than one way, is greatly influenced by reflex nervous impulses. It is doubtful whether the very considerable heat capacity of the bodies of large animals has been sufficiently taken into account in its bearing on the steadiness of the blood temperature. This in itself prevents any *sudden* change. In some animals, and apparently more especially in small animals—*e.g.*, the rabbit and guinea pig—the production of heat, as well as the loss, is very distinctly under the control of the nervous system, and is increased when the external temperature is lowered, and diminished when it is raised.

Of course, as your correspondent is doubtless aware, we do not really know what kind of a machine a muscle is, except that it is a machine by means of which the potential energy of the food is partly transformed into mechanical work and to a much greater extent into heat. Up to a certain limit the work and the heat *increase together*, although less heat is given off by an active muscle which is allowed on the whole to do external work than by the same muscle when it constantly undoes its own work.

G. N. STEWART.

New Museums, Cambridge, October 11.

THE following brief account of the working of the heat mechanism of the human body will, I hope, help to make clear to Mr. Cumming the problems of which he seeks the explanation.

The temperature of a man at the equator is within a degree Centigrade the same as that in the arctic regions. This is because, in the first place, in the arctic regions the loss of heat from the body is very slight, and in the tropics it is very great, for (a) in the tropics more perspiration is secreted by the skin, and this, in consequence of the high temperature of the air, evaporates very quickly, and hence the body is kept cool. It is true, as Mr. Cumming says, that in the tropics people may not be observed to perspire freely, but that is simply because as fast as the perspiration is secreted it is evaporated. It is what is called insensible perspiration. (b) More water is secreted by the bronchial mucous membranes in the tropics, and in consequence of the higher temperature of the air it, like the perspiration, evaporates very quickly. The excessive secretion of moisture by the body when the temperature of the air is high, is shown in a Turkish bath, and leads, in a bath of about two hours' duration, to a loss of weight amounting with some persons to three pounds, and to a great diminution in the quantity of urine secreted. (c) In the tropics the vessels of the skin are more widely dilated than in the arctic regions, hence there is more blood in it, and therefore heat is more readily radiated and conducted from the skin to the external atmosphere. (d) The specific heat of the body is very high, and so it cools very slowly in the arctic regions. Judging from some experiments I have made on animals, it is, at the usual temperature of the human body, well over 1·0. (e) The above facts are certain, but in addition, for all we know to the contrary, the skin may, under different conditions, have different radiating powers quite apart from the quantity of blood in it.

In the second place, although it has not been calorimetrically proved, *it is very highly probable that in the arctic regions the quantity of heat produced by the body is much greater than in the tropics*.

With regard to the second query of Mr. Cumming, no doubt, as he says, the human body in the tropics must often be the coolest of surrounding objects; in this case it cannot lose anything by radiation or conduction, but it is kept cool by the rapid evaporation of perspiration (usually insensible) and fluid secreted by the bronchial mucous membrane. Whether or not a man in the tropics produces any heat under such circumstances has not been *demonstrated*, but *probably, although the production of heat falls very low, it does not entirely cease*.

65 Harley-street, W. W. HALE WHITE.

Photographic Dry Plates

I HAVE found great difficulty in obtaining fresh photographic dry plates of whatever maker, from dealers, who frequently pass off upon the purchasers packets of plates which have been in stock for a long time, and consequently unfit for use. It has therefore occurred to me that this trouble might be avoided by the makers dating every packet as issued by them, thus following the custom of the Platinotype Company with their tins of paper. By such a system the purchaser would be able to protect himself,

and many makers' plates would be found much more satisfactory

I shall esteem it a favour if you will allow this letter to appear in your journal Enclosing my card, I subscribe myself,

October 17 PREVENTION

INVITATION TO OBSERVE THE LUMINOUS NIGHT CLOUDS[1]

SINCE the year 1885 a very remarkable phenomenon has been noticed in the sky in our latitudes, which well deserves to excite the interest of astronomers and geophysicists The following is the substance of what has so far become known regarding the so-called luminous night-clouds

In the latitude of Berlin the phenomenon shows itself only during a comparatively short period of the year from May 23 to August 11 While in the first years it was seen pretty frequently even before midnight, it has, during the last four years, rarely appeared except after midnight The phenomenon appears in the form of cirrus clouds, which come out bright on the twilight sky This especially distinguishes them from the ordinary cirrus-clouds, which, with the depths of the sun in which the luminous clouds are seen at present, come out dark on the light twilight sky The colour of the phenomenon is generally a bluish white, which becomes yellowish and reddish in close proximity to the horizon

Often repeated photographs which have been taken simultaneously at various points in the neighbourhood of Berlin, show that the altitude of the luminous clouds is constant and exceedingly great—82 kilometres In consequence of this great altitude, they receive light from the sun standing *below* the horizon, which makes them appear light on the twilight sky They are visible only so long as the sun shines on them, as soon as the shadow of the earth passes over them they become invisible As a rule they begin in the morning, shortly before twilight, and they disappear as soon as the sun stands higher than 8° to 10° below the horizon

Of late years these clouds have been seldom seen Within the period above stated, they occurred this year only about ten times, while in the first years they were very frequent Their appearance is subject to great changes, while they frequently exist only in a few little luminous stripes or patches, at times they appear in greater accumulations and with a more intense light Especially in the last days of the period, from August 2 until 6, their light seems to be considerable in our latitudes Generally they are observed in the proximity of the horizon—over that part of it under which the sun is

Frequent observations of the movements of the phenomena, which, after midnight, are always from the direction of N.E ± 40°, render it probable *that the movements are caused principally through the resisting medium of the mundane space* In accordance with this is the fact that in the half-year after its appearance in this country, the phenomenon has been observed repeatedly in the southern latitudes of 53° by the meteorological observer, Mr. Stubenrauch, in Punta Arenas, as well as several times by ship-captains

Other observations confirm the assumption of an annual wandering of this kind For instance, in Graham's-town under 33° S lat the phenomenon was observed on October 27, 1890,[2] and in Haverford under 40° N lat, according to written information it was observed on May 17, 1892 These dates, taken in association with the time of the appearance in this country, directly indicate a wandering of the phenomenon from N to S and back.

The luminous night-clouds decrease year after year in respect to the frequency of their appearance as well as to their extent and to their intensity of light The phenomenon therefore will entirely disappear within a few years It seems, however, that during the next two years observations will still be possible, which may give us information regarding several questions of extraordinary importance

Measurements of the apparent altitude of the upper limits of the luminous clouds, mainly in the time in which the upper limit of the twilight-segment has the comparatively small altitude of, say, 1° to 10°, would be of great value Such measurements will serve to decide the question whether the altitude of the clouds varies under different geographical latitudes, providing that the measurements always refer to such points as lie within the upper limits of the clouds, produced by the shadow of the earth

During the last few years the whole twilight-segment has been comparatively seldom filled out by the luminous night-clouds, and it may therefore frequently remain doubtful whether the highest point of the phenomenon really lies in the limit of the earth shadow In order to make sure that the measurements are adapted to their purpose, they must be repeated as often as possible in intervals of a few minutes In the evening this limit is generally recognized by the fact that within it parts of the phenomenon disappear from above, while towards morning new parts always become visible within the limit upwards The distance of the zenith of the upper limit of the luminous clouds in the vertical of the sun for the latitude of Berlin, presuming that the phenomenon stretches over the whole of the twilight-segment, may be seen from the following statement —

Depth of the sun below the horizon °	Zenith distance of the upper most limit °
12 0	80
12 5	83
13 0	85
13 5	86
14 0	87

Moreover, as by means of a telescope the upper limit of the phenomenon is generally seen a little higher than with the naked eye, it is desirable that the telescope should always be adjusted to the limit-line seen with the naked eye A comparison of the appearance seen with the naked eye with the one seen through the telescope, will enable the observer to discover easily the line corresponding to the one seen with the naked eye The exactitude of these measurements must be about 3′ to 6′, with respect to the azimuth and to the altitude, while the time should be exact within two to four seconds

The employment of photographic apparatus is of advantage for the indication of the place, as well as of the movements, of the phenomenon But only those kinds of apparatus are suitable in which the proportion of the diameter of the opening to the focal distance is at least 1 4 or greater If the proportion is smaller, the duration of lighting will last too long, and consequently, on account of the quick changings of the phenomenon, the details will get lost With an apparatus of which the proportion of the aperture-diameter to the focal distance is 1 . 3, the duration of lighting for the various depths of the sun below the horizon, on condition that the phenomenon is light in some degree, is as follows —

Depth of the Sun below the Horizon	Duration of Lighting s
9	16
10	21
11	27
12	35
13	48
14	72
15	122

[1] Scientific Journals are requested to reproduce this article
[2] Compare *Astr Nachr*, No 3008

Generally at the same time stars become visible on the photographic plate, through which, in association with the time of photographing, the direction of adjustment of the apparatus is ascertained (that is to say, the position of the axle of the apparatus is ascertained)

With regard to equatorial regions, it is of great importance that the exact time in which luminous night-clouds pass through them should be determined According to the observations hitherto made, the passing through the equator may take place in the time between the beginning of September and the end of October, and the return between the beginning of March and the end of April Under 20° S lat, the time of passing through will, in that case, be from the middle of September until the middle of November, and from the middle of February until the middle of April, and under 20° N lat from about the middle of March until the middle of May, and from the middle of August until the middle of October In consequence of the daily rotation of the earth round its axis together with the distinct movements of the earth, atmosphere, it may be that the passing through the equator does not take place in the simple manner here described It does not seem to be unlikely that the periods are not limited as exactly as stated

Moreover, it is probable that the luminous night-clouds consist of a gas which is condensed in consequence of the lower temperature prevailing in the altitude of 82 kilometres On the question relating to the nature of this gas depend several other cosmical questions for instance, with respect to the temperature of the air of the mundane space and the temperature of the atmosphere at the altitude of 82 kilometres, which will be answered through comparing experiments in the laboratory For this reason, spectrographs of the sunlight at low altitudes of the sun, in the season in which the phenomenon of the luminous night clouds is seen, are of great value Such spectrographs should be taken in the evening shortly before sunset, and in the morning shortly after sunrise

It appears that in the northern regions of the earth, in about 70° latitude, in the period from the middle of June until the middle of July, an especially great accumulation of clouds takes place, which, however, on account of the sun standing constantly *above* the horizon during this period, will be hardly visible It will, therefore, be of special advantage for these regions to take spectrographs of the sunlight at low positions of the sun

These short remarks regarding the importance of the phenomenon with reference to cosmical problems may serve to show that the observations necessary for the exploration of the subject are well within the sphere of astronomers and geophysicists There can be no doubt that the observations necessary for the solving of these questions are far beyond the capacity of a single institution. Those who take interest in the furtherance of the questions we have indicated are therefore requested to assist through one or other of the kinds of observation above noted in the investigation of the luminous night-clouds [1]

O JESSE.

Berlin Royal Observatory, September 1892

SOME OPTICAL ILLUSIONS [2]

A STRIKING illusion, first described by Zollner some thirty years ago, and usually called by his name, appears in Fig 1 Of the four main lines each adjoining pair seems to converge at one end, and to diverge at the other, whereas in reality the lines are all parallel The first step in an explanation of the illusion would be the determination of its essential factors, of its various forms, and of some general principle embracing under one formula its several varieties The next step would be to correlate this formulation with some recognized psychological principle The generalization is found

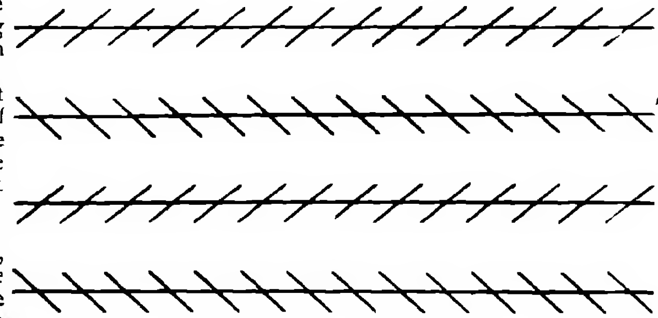

FIG 1

in the statement, that *the direction of the sides of an angle are deviated toward the direction of the angle*, and may be illustrated by reference to Fig 2 In this figure the continuation of the left horizontal line seems to fall below the right horizontal line, and the continuation of the latter above the former, in reality the two are continuous Similarly, if the continuations of the oblique lines be added, they will not seem continuous, but divergent slightly to one side or the other If now we call the direction of an angle the direction of the line that bisects it, then the deviation is what would result from a drawing up of the sides of the angle towards this central bisecting line, the left end of the left horizontal line would be drawn up, and the right end of the right horizontal line would be drawn down, and thus the two seem discontinuous The same would happen, though to a less degree, if either oblique line were omitted. There are many other ways of illustrating this fact. Instead of drawing the right line horizontal, we may incline its right end downwards slightly, and then it will seem continuous with the left horizontal line. We may apparently incline both lines so that they would converge towards a point between and below them, as in Fig 3 and the like. Two further points or corollaries should be noted (1) that the

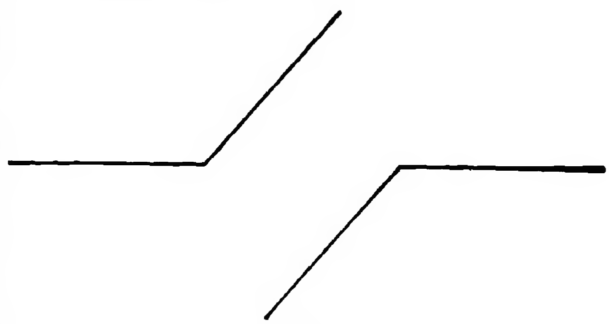

FIG 2

FIG 3.

[1] A publication, "Die leuchtenden Nachtwolken," by O Jesse, which may be expected within the next months, will contain details regarding the entire present position of these questions.

[2] Abstract of a paper on "A Study of Zöllner's Figures and other Related Illusions," by Joseph Jastrow, Ph D. (with the assistance of Helen West), being a part of "Studies from the Laboratory of Experimental Psychology of the University of Wisconsin" — *American Journal of Psychology*, vol iv. No. 3.

larger the angle the greater the deviation. Similar figures with acute angles substituted for the obtuse ones would show a scarcely perceptible illusion. (2) When obtuse

FIG. 4.

angles are combined with acute angles, the deviating effects of the former outweigh those of the latter. In Fig. 4 the effect of the angle ACD would be to make the

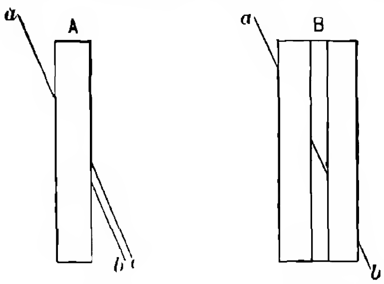

FIG. 5. FIG. 6.

line AB if continued fall *below* FG, while the effect of BCD would be to make AB fall *above* FG; the former outweighs the latter, and the illusion appears as directed

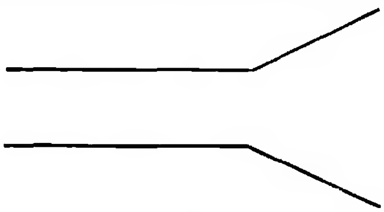

FIG. 7.

by the angle ACD. The angle BCE reinforces ACD, while ACE reinforces BCD. Angles greater than 180° do not come into consideration. When all the angles about a

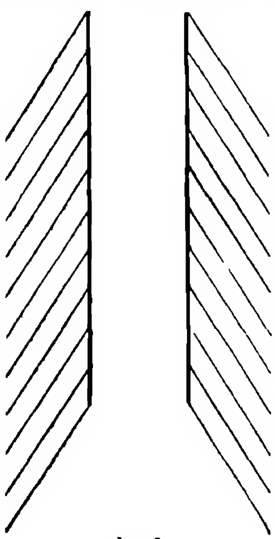

FIG. 8.

point are equal, *i.e.*, are right angles, the illusion disappears. Figs. 5 and 6 furnish other illustrations of the same principles. In Fig. 5 the line *a* seems continuous with *c* while it is so with *b*, and this because the obtuse angles formed by lines *a* and *c* with the vertical lines respectively, deviate the lines *a* and *c* towards the direction of the angles sufficiently to bring them in line with one another. Fig. 6 adds the further complication—explicable upon the same principles—that the line is deviated once in one direction and then in the reverse direction.

We have next to show that the illusion of deviation from

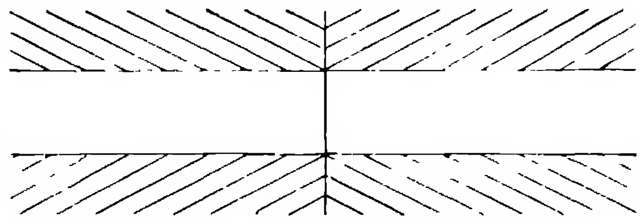

FIG. 9.

parallelism is similar to that from continuity. If the right-hand portion of Fig. 3 be rotated through 180° and placed below the left-hand portion, we have Fig. 7, in which we observe a tendency for the two horizontal lines to diverge on the left and converge on the right; this is just what our dictum demands. To strengthen this illusion we add more oblique lines, and thus more angles, the obtuse

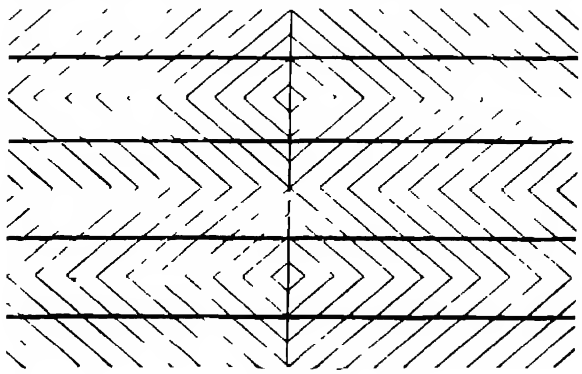

FIG. 10.

angles in all cases outweighing the acute ones—Fig. 8. We have now only to draw two figures like Fig. 8, side by side, and draw the oblique lines across the vertical ones (thus keeping the figure compact) to obtain Fig. 1, with which we set out. The possibilities of illusion do not stop here: by drawing the oblique lines in one direction on

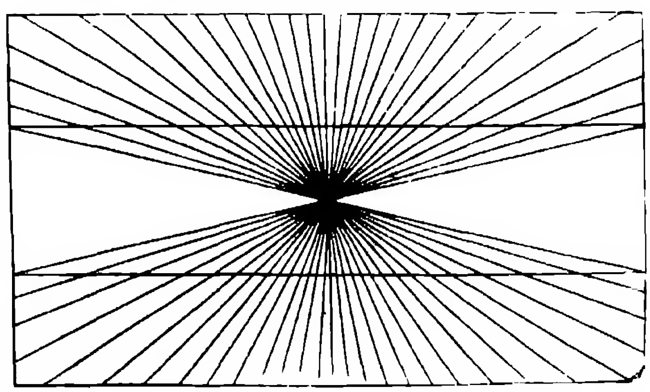

FIG. 11.

one side, and in the other direction on the other side, we can deviate the two halves of the same pair of parallel lines in opposite directions, as is done in Fig. 9; while most striking of all is the elaborate design of Fig. 10, in which it is difficult to realize that the four main lines are all straight and parallel. If the page be viewed with one

eye, and held horizontal nearly on a level with the eye, the true relations will appear Fig. 11 is valuable for its conclusive demonstration that the deviation is proportional to the angle, the increasing angles gradually bend the straight lines away from one another, and give them the gradual change of direction of curves These and other forms of illusion are all included in the generalization that the sides of an angle are deviated towards the direction of that angle[1]

The psychological principle with which this generalization may be correlated is the law of relativity This law emphasizes the fact that a sense-impression is not the same when presented alone and when in connection with other related sense-impressions We cannot judge the direction of lines independently of that of the angles whose sides they form As a further illustration of this principle it may be shown that angles will affect the apparent *lengths* of lines as well as their apparent *directions* If in Fig 12 we compare the horizontal portion of the uppermost figure with that of the lowest, it is almost impossible to believe that they are of equal length. The intermediate horizontal lines seem intermediate in length, and thus illustrate the fact that the apparent length of the horizontal lines is directly proportional to the size of the angles at their extremities The illusion would persist if we converted these figures into truncated pyramids by adding a line parallel to the horizontal line, and would then illustrate the fact that equal lines may be made to appear unequal by the effect of the areas whose contours they help to form A converse effect is illustrated in Fig 13 Here the upper figure seems larger than the lower, because its larger parallel side is brought into juxtaposition with the smaller parallel side of the lower figure This illusion and others show especially well when cut out of paper and held against suitable backgrounds As the figures are moved about one another the upper constantly becomes the larger More than two figures may be used, and a variety of such contrasts may be formed

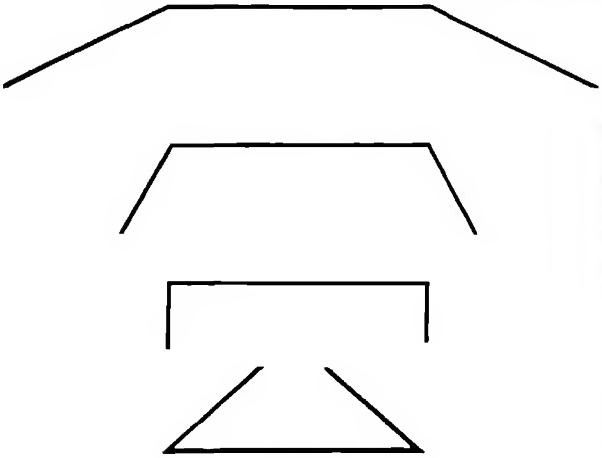

FIG 12

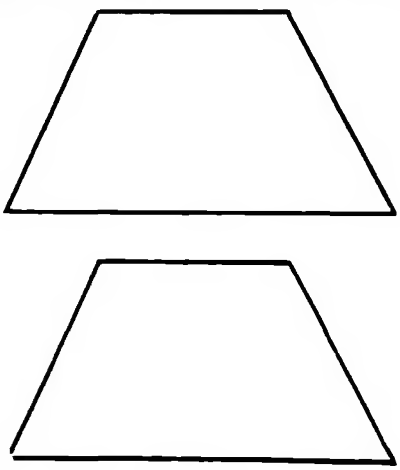

FIG 13.

The subject is by no means fully considered in these illustrations nor is the explanation offered as final or adequate If it seems to direct investigation into fruitful paths its chief purpose will be accomplished

[1] The reader is referred to the original paper for further illustration of this dictum, as well as for explanations of apparent exceptions and a discussion of the conditions affecting it.

THE NEW SATELLITE OF JUPITER

THE new number of the *Astronomical Journal* contains Mr Barnard's account of his discovery of this additional member of our system We make the following extracts - "Nothing of special importance was encountered until the night of September 9, when, in carefully examining the immediate region of the planet Jupiter, I detected an exceedingly small star close to the planet, and near the third satellite I at once suspected this to be a new satellite I at once measured the distance and position-angle of the object with reference to satellite three I then tried to get measures referred to Jupiter, but found that one of the wires had got broken out and the other loosened Before anything further could be done the object disappeared in the glare about Jupiter Though I was positive the object was a new satellite, I had only the one set of measures, which was hardly proof enough for announcement I replaced the wires the next morning The next night with the great telescope being Prof Schaeberle's, he very kindly gave the instrument up to me, and I had the pleasure of verifying the discovery and secured a good set of measures at elongation In these observations, and those of the succeeding night, only distances from the following limb of Jupiter could be measured These were observed with the wires set perpendicular to the belts The planet was thrown outside the field the satellite bisected, and then the limb brought in and bisected also This method would not permit any measures from the poles of the planet for latitude On the 12th I inserted a strip of mica, carefully smoked, in front of the field-lens, for occulting the planet This served admirably, permitting the satellite and planet to be both seen at once, and measures from the polar limbs could be made with great ease The observations of the satellite from the 12th were all thus made

"To avoid any personal equation I have on each night measured the diameters of the planet, for use in reducing the observations to the centre of Jupiter Since the 12th, these have been measured through the smoked mica, so as to avoid introducing any error from the reduced brightness of the planet The diameters were measured by the method of double distances Just what the magnitude of the satellite is, it is at present quite impossible to tell Taking into consideration its position, however, in the glare of Jupiter, it would, perhaps, not be fainter than the thirteenth magnitude It will only be possible to settle this question with any certainty by waiting until some small star of the same magnitude is seen close to Jupiter, and then after determining its magnitude when away from the planet In general the satellite has been faint—much more difficult than the satellites of Mars On the 13th inst, however, when the air was very clear, it was quite easy.

"It is scarcely probable that this satellite will be seen

with anything less than twenty-six inches, and only with that under first class conditions I give here the observations that I have so far obtained, and defer any suggestions as to a name until a later paper It certainly should not disturb the present harmony existing in the Roman numerals already applied to the satellites

"It is so wholly different from any of the other moons in physical aspect, that it ought, in a sense, to be considered independent of them, and simply be called, say, the fifth satellite, with a suitable mythological name

"It will be seen that on three of the dates of observation the east elongation is well covered in the measures"

Plotting the observations at elongation, the following values of the distance were obtained —

				From Jupiter's centre Miles
September 10 (apparent)	61″ 04	log R =	7 08267	112250
,, 12 ,,	61″ 55	,,	7 08452	112750
,, 14 ,,	61″ 60	,,	7 08324	112400

From these the following periods result, using the well-known formula -

$$P = p\sqrt{\frac{m}{M}\,\frac{R^3}{r^3}}$$

	h	m
September 10 period	11	47 6
,, 12 ,,	11	52 3
,, 14 ,,	11	49 0
Mean	11	49 63

The observations, all made in standard Pacific time (eight hours slow of Greenwich) are given at length in the *Journal*

The latitude measures show that the satellite's orbit lies in the plane of Jupiter's equator, and Mr Barnard holds that it is consequently a very old member of Jupiter's family, "since it would doubtless take ages for the orbit to be so adjusted" W L

NOTES

The ordinary general meeting of the Institution of Mechanical Engineers will be held on Wednesday evening, October 26, and Thursday evening, October 27, at 25, Great George Street, Westminster The chair will be taken at half-past seven p m on each evening by the President, Dr William Anderson, F R S The ballot lists for the election of new members, associates, and graduates having been previously opened by the Council, the names of those elected will be announced to the meeting The nomination of officers for election at the next annual general meeting will take place The following papers will be read and discussed, as far as time permits —Second Report of the Research Committee on the value of the steam-jacket, by Mr Henry Davey, Chairman (Wednesday), and experiments on the arrangement of the surface of a screw propeller, by Mr William George Walker, of Bristol (Thursday)

We are asked to intimate that the late Prof Adams has left a number of separate copies of certain of his mathematical and astronomical papers, and that Mrs Adams will be happy to distribute them to scientific friends who make application for them by letter addressed to her at 4, Brookside, Cambridge

The Harveian oration was delivered on Tuesday afternoon by Dr J H Bridges He presented an able and most interesting sketch of the scientific influences amid which Harvey's work was done, and the relation of his great discovery to later research

The controversy as to vivisection is still going on in the *Times* For the present, therefore, it may be enough for us to reproduce the letter which was signed by Sir Andrew Clark, Sir James Paget, Dr Samuel Wilks, and Sir George Humphry, and printed in the *Times* on Saturday last It is as follows —

"Having already expressed our views, personally or by letter, to the Church Congress, we decline to enter into any further public discussion on the question of so called 'vivisection,' for the following reasons, the statement of which we make solely because we think it is due to your readers —Firstly, after full consideration, we are satisfied that the scientific aspect of this question cannot receive adequate and just treatment in the columns of a newspaper Secondly, because it is hardly possible for us to name any progress of importance in medicine, surgery, or midwifery which has not been due to, or promoted by, this method of inquiry"

Prof Virchow was invested, on Saturday last, with the insignia of office as Rector of the University of Berlin. He chose "Learning and Research" as the subject of his address He acknowledged that study had contributed greatly to create a mutual basis of understanding and a common educational foundation for the peoples of Europe, strengthening at the same time the idea of consanguinity That state of things, however, was, he thought, entirely changed, and he contended that the turning-point in the supremacy of the classical languages had been reached "A grammatical education is not the means for progressive development demanded by our youth Mathematics, philosophy, and the natural sciences give young minds so firm an intellectual preparation that they can easily make themselves at home in any department of learning"

Prof Berg has succeeded the late Dr Burmeister as director of the National Museum in Buenos Ayres

Dr G v Lagerheim, at present director of the Botanic Garden at Quito, Ecuador, has been appointed curator of the museum at Tromso, Norway

Mr W G Ridewood, B Sc, of the Royal College of Science, South Kensington, Assistant to the Director of the Natural History Museum, has been appointed Lecturer in Biology to the St Mary's Hospital Medical School

The October number of the *Kew Bulletin* opens with a section giving some interesting information as to Lao tea Some time ago a singular method of using the leaves of what has since been proved to be the Assam tea plant of commerce (*Camellia thea/era*) was brought before the Society of Arts by Mr Ernest Mason Satow Amongst the Laos, a people inhabiting a district of Siam, in the neighbourhood of Chiengmai, the tea leaves are not used for making an infusion as in other countries, but are prepared wholly for the purpose of chewing The leaves are first steamed and then tied up in bundles and buried in the ground for a period of about fifteen days Leaves thus prepared, called locally "mieng," are said to keep for two years or more The habit of chewing "mieng" is almost universal among the Laos, and to men engaged in hard work, such as poling or rowing, it is said to be almost indispensable The *Bulletin* prints a correspondence in which the result of an inquiry made by Kew in regard to the plant yielding "mieng" and the method of preparation is detailed.

The other sections in the October number of the *Kew Bulletin* deal with Chinese silkworm gut, mangrove bark and extract, Burmese black rice; Mauritius tea, potato disease in Poona, British North Borneo, and Allouya tubers There are also some miscellaneous notes

We learn from the *Journal of Botany* that Dr H Trimen, F R S, the Director of the Botanic Gardens at Paradeniya Ceylon, has received the sanction of the Government to proceed with the publication of the flora of that island The work will be published in parts by Messrs Dulau and Co., and will form two vols. octavo, together with a quarto atlas of 100 coloured plates,

drawn by the native Cingalese artists attached to the gardens The first part is now in the press The book is more especially designed for use in the colony, and will enter into more local detail than has been hitherto the practice in the Colonial floras published by the Government

MR G HOGBEN delivered an excellent address lately before the Canterbury College Science Society, New Zealand, on earthquakes In the course of his remarks he described the system which, for the last three years, has been in force in New Zealand for the observation of earthquake phenomena and the telegraphing of the results to a central station This system has been adopted in Victoria, New South Wales, South Australia, and Tasmania, and will probably be shortly adopted in Queensland The various colonies exchange reports with New Zealand, and it is proposed that the system shall be further extended, so that the colonies may be brought into communication with the islands of the Pacific and America and Japan

A REUTER telegram despatched from Vienna on October 14 announced that reports had reached that city of the occurrence of violent earthquake shocks in Eastern Europe The vibrations were strongest in Roumania, being felt at Bucharest, where they lasted 15 seconds, and at Galatz during 30 seconds At Oltenizza the shock lasted fully 90 seconds, and did considerable damage in the town A shock was felt at Sofia on October 14, at seven o'clock A M , and also at Philippopolis, Varna, and Rustchuk The seismic wave passed from south to north, the vibration lasting several seconds, and being accompanied by subterranean rumbling

THE depression over the Bay of Biscay referred to in our last issue took a very unusual route, the track being almost circular, moving first in an easterly and north easterly direction towards the north of France, and then recurving by the south west of England back to the Bay of Biscay, when it again travelled to the eastward The disturbance caused to the weather in this country was very great and the rains were very heavy, with serious floods, especially in Wales and the midland and northern counties In Yorkshire it rained almost incessantly from Thursday to Saturday, a fall of 1½ inch being measured in one day The weather was still further disturbed by an area of low pressure lying over the north of Germany between Sunday and Monday, which caused disastrous gales and further heavy rains in the eastern part of the country. The temperature has been very low for the season, the daily maxima scarcely reaching 55 in any part of the kingdom, owing to the persistent northerly and north easterly winds Towards the close of the period temperature fell several degrees lower, with sharp day frosts in Ireland, under the influence of an anti-cyclone, which spread over the country from the Atlantic, while hail and sleet showers fell in places The *Weekly Weather Report* of the 15th inst showed that the temperature of the past week was everywhere below the mean, being as much as 4° in the south-west of England and 5° in the south of Ireland The rainfall greatly exceeded the average over the north and east of England

AN anemometer by M Timchenco of a novel construction is described by Prof Klossovsky, of the Odessa Observatory, by which both the wind direction and velocity are marked on a cylinder by one symbol The recording apparatus is moved by clockwork and the indications are made by electrical contacts The duration of the contact depends upon the velocity of the wind, a light wind producing a contact of longer duration than a strong one The indications are by means of arrows printed on the paper covering the cylinder, which show the direction of the wind, and the number of arrows marked on a length of paper corresponding to one hour furnishes data for finding the velocity by an empirical scale determined by comparison with a Robinson's anemometer The apparatus only requires to be adjusted twice a month, or in some instruments only once a month, and calls for no attention in the meantime A battery cell is sufficient to produce the contact, for most of the work is done by means of weights

THE *Annuaire* of the Municipal Observatory of Montsouris for the years 1892 93 contains, in addition to the usual tables showing *inter alia* the extremes of temperature at Paris since 1699 and the monthly rainfall values since 1690, much useful information with reference to the climate and the microscopic examination of the quality of the air Although it does not fall within the province of the observatory to issue weather forecasts, applications for such information are sometimes received and answered, in the interest of agriculture The opinion is expressed that by basing the calculations on the general methods adopted by Laplace in his memoir entitled "Probabilité des causes d'après les événements," it is not impossible to give a long forecast which may be at times of much use Some interesting remarks are also made as to the possibility of foreseeing the character of the summer from the weather experienced in the early spring, based chiefly on the time of the appearance of the north east winds, and the differences in their usual strength and physical qualities, in connection with the transparency of the air The results of the analysis of the air show that the minimum amount of carbonic acid occurs between May and September, and that the amount at night is greater than during the day

THE new University of Chicago has decided that its work shall go on all the year through, including the summer months According to the New York *Nation*, the calendar year is divided into four quarters of twelve weeks each, beginning respectively on the first days of October, January, April, and July , and at the end of each quarter there is to be a recess of one week Each quarter consists of two terms of six weeks No student is to be held to an attendance of more than three quarters, or six terms, in each year, so that the normal academic year is no longer than at other colleges Each student is to begin his academic year whenever he is ready, and to take his quarter's vacation whenever it suits his convenience He may even take his two terms of vacation in different quarters

AN investigation of the phenomena exhibited at the negative poles of vacuum tubes appears in vol xl of the *Sitzungsberichte* of the Prussian Academy Professor E Goldstein considers that the term "stratification" as applied to the light at the cathode is a misnomer, since two at least of the strata can be shown to pervade the entire region of luminosity The light nearest the cathode is yellowish, and about 1 cm thick Next comes Crookes' "dark space," which in reality shines with a faint blue light. Then follows the third and most highly luminous layer, whose colour changes from a blue to a violet as the exhaustion is carried further The first layer was shown to be a separate phenomenon on a previous occasion The so called second layer shows the peculiarity of rectilinear propagation It is emitted from the electrode normally to its surface, or very slightly divergent, whereas that of the third layer spreads throughout the bulb and even passes round corners. The second layer is best shown by concave poles, which concentrate the light at the centre of curvature If observed through a blue glass, which cuts off the third layer, it is seen to diverge from the focus and impinge upon the wall of the bulb. The phosphorescence observed in the glass where it is struck by the "radiant matter" is due to this part of the light only, and not to the third layer It is this also which produces the well-known phenomena of shadows. A glass rod laid in its path casts a shadow through the blue space, which is, however, relieved by the purple luminosity of the third layer The former is also the only light deflected by a second cathode It is to be concluded that the light at the negative pole of a vacuum tube consists of three different species, each pervading the others, but having distinct and characteristic properties of its own

IN the current number of the "Annals of Scottish Natural History," Mr E P Knubley discusses the question whether legislative protection is required for wild birds' eggs. He suggests that the most practicable plan might be for Parliament to grant powers to the County Councils from time to time, and as necessity arose, to place certain portions of a district, such as mountains, commons, waste places, lakes and meres, or portions of cliffs or foreshores, under an Act for specified months in the year—say, from April 1 to June 30 What, however, is most urgently wanted, as Mr Knubley says, is that landlords and occupiers shall, as far as possible, protect birds breeding on their property or "occupation"

MR ERNEST ANDERSON recently read before the Field Naturalists' Club of Victoria an interesting paper on some Victorian Lepidoptera He said that a great charm accompanied the rearing out of the Victorian species, because the results were very frequently of a most unlooked for character The Victorian forms followed the same rule as many plants and animals in having characteristics and habits purely Australian, and not only so, but they helped to bridge over the sharply defined divisions known in Europe, and merged the various groups so imperceptibly into each other that it was hard to say where one ended and another began. Speaking of the processional caterpillars (*Teara melanosticta*), Mr Anderson described how a female laid some ova in a small box and covered them very thickly with yellow down Very shortly afterwards a thread like structure was visible, which close examination revealed to be composed of newly-hatched caterpillars in Indian file, each having its head close up to the tail of its forerunner, and the whole line moving simultaneously with mathematical precision

THE use of gas engines does not seem to be nearly so common in the United States as in Great Britain According to the *Railroad and Engineering Journal*, they are generally regarded in America as of service for light work only, and it is with some surprise that our contemporary has noted the advertisement of an English firm, which keeps all sizes up to forty horse power in stock, and offers to furnish single engines of any size up to two-hundred and-fifty-horse power This much exceeds the capacity of any gas engine built until very recently

THE U S Department of Agriculture has published a valuable account, by Harvey W Wiley, of experiments with sugar-beets in 1891 The experiments were divided into three classes, (1) culture of the sugar beet conducted by farmers in different parts of the country, (2) culture of the sugar-beet conducted by the agricultural experiment station of Wisconsin and numerous farmers in Wisconsin, under the direction of the agricultural experiment station of that State, by authority of the Secretary of Agriculture, (3) experiments conducted at the beet sugar experiment station of the Department at Schuyler, Nebraska

WE learn from the *American Naturalist* for October that the vertebrate fossils collected by Prof Marsh, to which we lately referred, are not likely, after all, to be soon exhibited in the National Museum at Washington Our contemporary says "One side of a small room is the only space at present occupied by the material in question, and it is safe to say that no other space has been yet provided As the National Museum committed the error at its establishment of attempting an exhibit of modern human industries, as we pointed out at the time, the space for scientific exhibits is necessarily greatly curtailed. The necessities of this department require the erection of a new building, and until that is done it is safe to say that the vertebrate collections of the U S. Geological Survey will not be exhibited."

SLEEP is one of the least understood of physiological phenomena A new theory of it (we learn from the *Revue Scientifique*) has been offered by Herr Rosenbaum He supposes the essential fact in the fatigue of the nervous system leading to sleep to be a hydratation of the nerve-cells, an increase of their water-content The greater the hydratation, the less the irritability This hydratation arises through chemical change of the nervous substance during activity A small part of the water escapes by day through the lungs, but the greater part is eliminated during sleep Its passage into the blood takes place by virtue of the laws of diffusion, and depends on the quantity and density of the blood, its amount of fixed principles, its speed of flow, &c Elimination of the expired air takes place according to the laws of diffusion of gases The assimilable substances of the body take the place of the water eliminated in sleep The repair of the physical and mental forces through sleep is due to this elimination and replacement Intelligence is in inverse ratio of the proportion of water in the brain, and may be measured by this proportion, at least in the child It may be doubted whether this theory explains the sleep of hibernating animals, or that caused by opium and anæsthetics

D J MADISON TAYLOR has been elaborately investigating the various problems relating to physical exercise in health and as a remedy, and some of the results are set forth in the *Journal of the Franklin Institute* for September and October One conclusion is, he says, uniformly prominent in the instances of damage from boat and other racing Always the training has been "either insufficient or bad, or both"

IN one of the papers contributed to the third number of the Trinidad Field Club's Journal, Mr J Edward Tanner describes some interesting observations of the habits of the Parasol or Leaf Cutting Ants Two nests of these ants were on his table at the time when his paper was being prepared He begins by noting that all in Trinidad who are interested in such subjects know the hurried manner in which a parasol ant returns to her nest (all leaf cutting workers are females), bearing erect in her mandibles the portion of leaf she has herself just cut off, and apparently running home with it in triumph These foragers, for they are the ones who supply the household, carry their portion of a leaf well into the nest, drop it, and return for another piece, nor do they cease doing so till the supply is more than those in the nest require Mr Tanner could not induce the ants in one of his nests to carry any leaf whatsoever into the nest, till one day he coaxed a small worker to do so As she entered she was caressed by those in the nest, who stroked and patted her with their antennæ The small piece of leaf she had brought was at once taken by one of the larger workers, to go through its various processes, while she returned for more, and she continued to bring in pieces till late in the evening Strange to say, none of the others followed her example Even four weeks later only two or three carried in any portions of leaf Mr Tanner suggests that this may have been due to the fact that the queen was accidentally killed while the nest was being taken. The other nest had a queen, and with it there was no trouble, for the ants kept themselves well supplied from whatever was offered to them on their feeding ground, whether rose leaves, plumbago, or quis-qualis. "Each forager," says Mr. Tanner, "drops her portion of leaf in the nest, which is taken up as required by the small workers, and carried to a clear space in the nest to be cleaned. This is done with their mandibles, and if considered too large it is cut into smaller pieces. It is then taken in hand by the larger workers, who lick it with their tongues. Then comes the most important part, which almost always is done by the larger workers, who manipulate it between their mandibles, mostly standing on three legs. The portion of leaf is turned round and round between the mandibles, the ant using her palpi, tongue, her three legs, and her antennæ while doing so It

now becomes a small, almost black ball, varying in size from a mustard seed to the finest dust shot, according to the size of the piece of leaf that had been manipulated. The size of the piece of leaf is from an ¼ by ⅛ of an inch, by ¼ by ¼ of an inch I do not wish it to be understood that only one class of workers manipulate the leaf, for all seem to take to it very kindly on emergency Even the smallest workers will bring their tiny ball to where the fungus bed is being prepared These balls, really pulp, are built on to an edge of the fungus bed by the larger workers, and are slightly smoothed down as the work proceeds The new surface is then planted by the smaller workers, by slips of the fungus brought from the older parts of the nest Each plant is planted separately and they know exactly how far apart the plants should be. It sometimes looks as if the plants had been put in too scantily in places, yet in about forty hours, if the humidity has been properly regulated, it is all evenly covered with a mantle, as if of very fine snow It is this fungus they eat, and with small portions of it the workers feed the larvæ"

MR. O P HAY records in the latest volume of the Proceedings of the U S National Museum a curious habit of horned toads. Some years ago two boys from Texas, whose family had moved into his neighbourhood, showed him a few lizards belonging to the genus Phrynosoma, and popularly called horned toads The boys declared that these little animals, when teased, would sometimes squirt blood out of their eyes Mr. Hay did not think much about the matter at the time, but was lately vividly reminded of it in the department of reptiles in the National Museum Near his desk there was a specimen of *Phrynosoma coronatum*, which had been sent from California by a member of Dr Merriam's exploring party About August 1 it was shedding its outer skin, and the process appeared to be a difficult one, since the skin was dried and adhered closely One day it occurred to Mr Hay that it might facilitate matters if he gave the animal a wetting, so, taking it up, he carried it to a wash-basin of water near by and suddenly tossed the lizard into the water. "The first surprise," says Mr Hay, "was probably experienced by the Phrynosoma, but the next surprise was my own, for on one side of the basin there suddenly appeared a number of spots of red fluid, which resembled blood" He immediately recalled what the boys had told him of the ability of horned toads to squirt blood, and he concluded that this was a good time to settle the question whether this fluid was blood or not A microscope was soon procured and an examination was made, which immediately showed that the matter ejected was really blood A day or two afterwards Mr Hay was holding the lizard between his thumb and middle finger, and stroking its horns with his forefinger All at once a quantity of blood was thrown out against his fingers, and a portion of it ran down on the animal's ne and this blood came directly out of the right eye Mr Hay has since found that the phenomenon has been noticed by other observers, and, while he was preparing his paper, his attention was called to the fact that more than twenty years ago Mr A R Wallace read before the Zoological Society of London letters from a correspondent in California, who described this creature as squirting from one of its eyes "a jet of bright red liquid very much like blood"

MESSRS. PERCIVAL AND CO announce the following works:— "Geometrical Drawing," by A. J Pressland, "Lessons on Air," by A. E. Hawkins, "The School Euclid," an edition of Euclid, Books I–vi, with Notes and Exercises, by Daniel Brent; and a series of elementary text-books entitled "The Beginner's Text-books of Science," of which Mr G. Stallard is the general editor.

MESSRS. GEORGE BELL AND SONS have published a second edition of Mr. A. J Jukes-Browne's "Student's Handbook of Physical Geology" The author explains that in preparing this edition he has spared no pains to make it a trustworthy handbook for those branches of the science to which it relates

MESSRS. WHITTAKER AND CO have issued for the benefit of amateur coil-makers a practical manual on "Induction Coils," by G E Bonney The author's object has been to place in the hands of his readers "a cheap and handy volume giving a general insight into the construction of ordinary spark coils, medical coils, and batteries for working them" There are more than a hundred illustrations

MESSRS LONGMANS, GREEN, AND CO have issued a new edition, revised and largely re-written, of the well-known "Outlines of Psychology," by Prof James Sully

MESSRS. CHAPMAN AND HALL will shortly publish a work by Rev H N Hutchinson, entitled "Extinct Monsters" It will be illustrated by Mr J Smit, who has made twenty-four restorations of antediluvian animals The book is not intended for geologists only, but for all who are interested in the study of animal life Dr Henry Woodward, F R S, keeper of geology, Natural History Museum, contributes a preface

THE new number of *Records of the Australian Museum* (Vol III, No 2) opens with a paper, by Mr J Douglas Ogilby, on some undescribed reptiles and fishes from Australia To the same number Mr C Hedley contributes a paper on the structure and affinities of *Panda Atomata*, Gray Mr. A North has a note on *Manucodia comrii*, Sclater

THE University College of North Wales has published its calendar for the year 1892 93

GLYCOL aldehyde, $CH_2OH\ CHO$, the hitherto almost unknown first aldehyde derived from glycol, forms the subject of a communication to the current number of the *Berichte* by Prof Emil Fischer and Dr Landsteiner. This substance acquires additional interest when the ordinary sugars are defined as aldehyde- or ketone-alcohols, for it then becomes the first member of the series. Prof Fischer now shows how glycol aldehyde may readily be obtained, discusses its properties, and points out that by its polymerisation a new sugar is obtained, tetrose, the first synthetical sugar containing four atoms of carbon The only evidence hitherto published of the existence of glycol aldehyde is that afforded by the work of Abeljanz and Pinner The former chemist considered that he had obtained it by heating di-chlor ether with water, and by the action of sulphuric acid upon mono chlor-hydroxy-ether. But upon repeating the work of Abeljanz, Prof Fischer finds that the substance considered, upon very slight evidence, to be glycol aldehyde is another compound altogether. Pinner afterwards attempted to obtain it by decomposition of a substance discovered by him, glycol acetal, with acids, but Prof. Fischer finds that this reaction only occurs under conditions such that the glycol aldehyde is itself also decomposed. In view of the formation of glyceryl aldehyde by the action of baryta upon acrolein dibromide, a reaction now of historical importance as being the one which led Prof Fischer to the first synthesis of grape sugar, it was thought probable that glycol aldehyde might be similarly obtained by the action of baryta upon the mono-bromine derivative of aldehyde, $CH_2Br\ CHO$. Mono-brom-aldehyde, however, had never been hitherto obtained, so Prof. Fischer and Dr Landsteiner first sought a method for its preparation. They eventually obtained it, as a viscid colourless liquid of powerful tear-exciting odour, by heating mono-brom-acetal, $CH_2Br\ CH\begin{cases}OC_2H_5\\OC_2H_5\end{cases}$, with anhydrous oxalic acid. When the mono-brom-aldehyde thus

obtained was mixed with water containing barium hydrate partly in solution and partly in suspension, and the whole maintained for half an hour at 0°, the odour of the brom aldehyde disappeared almost completely Upon removal of the baryta by sulphuric acid and the hydrobromic and sulphuric acids by lead carbonate, the filtered liquid was found to contain glycol aldehyde, which could be concentrated by evaporation over oil of vitriol *in vacuo* The solution of glycol aldehyde reduces Fehling's solution with great energy at the ordinary temperature When warmed with a solution of phenylhydrazine in acetic acid crystals of an osazone are deposited, just as happens in the case of other members of the series of sugars Glycol aldehyde is readily oxidized by bromine water to glycollic acid, $CH_2OH.COOH$. When treated with a dilute solution of sodium hydrate polymerization occurs, a sugar of the composition $C_4H_8O_4$, the first synthetical tetrose, being formed, which is readily isolated in the form of its osazone (phenyl hydrazine compound) This osazone appears to be identical with one obtained by Prof Fischer from one of the oxidation products of natural erythrite The preparation of glycol aldehyde completes the synthesis of the whole of the members of the series of sugars, from the first member up to the sugars containing nine atoms of carbon, with the exception of pentose This latter sugar Prof Fischer hopes shortly to obtain from the tetrose above described

THE additions to the Zoological Society's Gardens during the past week include a Grivet Monkey (*Cercopithecus griseo viridis* ♀) from Zanzibar, a Bengal Fox (*Canis bengalensis*) from Pondicherry, presented by the Rev J W Scarlett, a —— Monkey (*Cercopithecus sp inc*) from the Zambesi, presented by Mr Joseph A Moloney, a Bonnet Monkey (*Macacus sinicus*) from India, a White Stork (*Ciconia alba*), European, presented by the Rev Sidney Vatcher, a Mona Monkey (*Cercopithecus mona*) from West Africa, presented by Miss Synge, a Hairy Armadillo (*Dasypus villosus*) from South America, presented by Mr J H Hamilton Benn, a Common Badger (*Meles taxus*), British, presented by Mr. W Butler, a —— Galago (*Galago sp inc*) from East Africa, presented by Mr Thomas E C Remington, , an —— Ichneumon (– ——), a Purple crested Touracou (*Corythaix porphyreolophus*), two Black Gallinules (*Limnocorax niger*), a Tambourine Pigeon (*Tympanistria bicolor*), an Emerald Dove (*Chalcopelia afer*), four Half collared Doves (*Turtur semitorquatus*), a —— Fruit Pigeon (*Treron sp inc*), four —— Tree Frogs (*Hylambates maculatus*), seven Smooth clawed Frogs (*Xenopus lævis*) from East Africa, presented by General Mathews, three Mitred Guinea Fowls (*Numida mitrata*), a —— Snake (*Philothamnus semivariegatus*) from East Africa, presented by Mr. W Hall Buxton MacDonald, M D, a —— Pratincole (*Glareola sp inc*), a Half-collared Dove (*Turtur semitorquatus*), a Nilotic Crocodile (*Crocodilus niloticus*) from East Africa, presented by Mr R MacAllister, two —— Francolins (*Francolinus* ——), a - Coucal (*Centropus* -——), five Half collared Doves (*Turtur semitorquatus*) from East Africa, a Black tailed Hawfinch *Coccothraustes melanurus*) from Japan, presented by Mr F Pordage, a Flap necked Chameleon (*Chamæleon dilepis*), two Square marked Toads (*Bufo regularis*) from East Africa, presented by Mr E Millar, a Galeated Pentonyx (*Pelomedusa galeata*), two —— Skinks (*Gerrhosaurus major*), five —— Geckos (*Hemidactylus mabouia*), three —— Lizards (*Mabuia striata*) from East Africa, presented by Mr Frank Finn, F Z S, a Common Quail (*Coturnix communis*), captured at sea, presented by Mr A Torrie, a Honey Buzzard (*Buteo apivorus*) from France, presented by M S A Pichot C.M.Z S, a Burrowing Owl (*Speotyto cunicularia*) from South America, presented by Mr R. B Shipway, two Common Boas (*Boa constrictor*) from Trinidad, presented by Messrs Mole and Urich; a Black-headed Lemur (*Lemur brunneus*) from Madagascar, a Yellow tailed Rat Snake (*Spilotes corais*) from Trinidad, deposited, an African Wild Ass (*Equus tæniopus*), born in the Gardens

OUR ASTRONOMICAL COLUMN

A NEW COMET —A telegram from Kiel announces the discovery of a new comet by Prof Barnard on October 12 last, at 17h 12 2m mean Lick time The position, as therein stated, was R A 293° 29′, and Declination + 12° 33′ As this new comet is termed "very dim," as seen with the large Lick refractor, it is needless to say that few instruments can at present observe it

OUR SUN'S HISTORY —The question of "How our Sun commenced to grow hot," is the subject of an article by Lord Kelvin in the October number of *L'Astronomie* In these few pages he deals with various questions, among which may be mentioned What is the temperature of the Sun? Is it increasing or diminishing? What was the state of the matter constituting our Sun before it was united into a single mass and began to grow hot? The answer to the last question leads him into the method of construction of our solar system In considering the question of the encounter between two bodies as the origin, he finds that the probability of such an encounter between two neighbouring stars belonging to a large number of bodies, attracting one another mutually, and scattered in space, is much greater if they are at rest than if they are moving, even if their velocities are greater than those acquired in falling from rest As an explanation of this Lord Kelvin takes the case of two solid and cold bodies of diameters equal to half that of the sun, and of mean densities equal to that of the earth, and supposes them at rest, the mean distance between each other being that of the earth from the sun The collision caused by mutual attraction will transform the bodies into a fluid, incandescent mass, and he describes how this mass will arrange itself round this surface of collision The next case he takes is similar to the one above, only the bodies have originally considerable velocities Further on, as a special instance, he assumes the presence of 29 millions of solid cold globes, each having a mass equal to that of our moon, and the total masses of which are equivalent to that of our sun These bodies, absolutely at rest, are supposed to be disseminated uniformly on the surface of a sphere (radius = terrestrial orbit), and allowed to fall towards the centre of the sphere by attraction The result, to state briefly, is a mass of highly heated vapour, which afterwards expands and contracts consecutively, forming a gaseous nebula, measuring forty times the radius of the terrestrial orbit By supposing that, instead of absolute rest at the commencement, these moons have a certain movement, the total sum of which represents a moment of rotation round a certain axis, equal to the moment of rotation of the solar system, this nebula would be a more or less facsimile of our solar system in its earlier stage, as figured out by La Place for his nebular theory Thus this theory, "founded by La Place on the history of the sidereal universe such as Herschel observed, and completed in its details by his profound dynamical judgment and imaginative genius, appears to-day a truth demonstrated by thermodynamics" For the theory of the sun, Lord Kelvin says in conclusion that the antecedents immediately before incandescence cannot be definitely stated, since the latter may have been caused by large and few bodies, or by agglomerations of such bodies as meteorites

SILVERING GLASS MIRRORS — Mr. Common, in the *Observatory* for October, gives a brief account of various processes and methods for producing good reflecting surfaces. In the short historical sketch we find that the modern process is due to an observation of Baron Liebig, who, in 1835, found that on heating aldehyde with an ammoniacal solution of silver in a glass vessel a brilliant deposit of metallic silver was deposited on the surface of the glass. In all the methods used up till quite recently the surface to be silvered had to be suspended over the bath, owing to the formation of mud which settles down and prevents the proper deposition of silver, thus really large surfaces could not be dealt with This was the case with Mr Common's 3 foot, a pneumatic arrangement being made to hold the mirror by the back In dealing with the 5 foot, this method could not be so easily applied, and experiments were made to find some means by which this "mud" could be entirely eliminated. This was successfully

done by omitting the potash from the bath. One curious fact of observation is that the mirrors experimented on never seemed to take the first application of the silvering solution, but on being recleaned with nitric acid the second was always successful. Why this should be so does not seem to be easily explained, for Mr. Common only commits himself to the statement that "the nature of the liquid other than distilled water last in contact with the surface of the mirror seems to be the determining thing."

Himmel und Erde.—In this magazine for October there is a most interesting set of articles, of which we mention the following:—"Meteorology as the Physics of the Atmosphere," by Herr Wilhelm von Bezold. This comprises a general summary of the proceedings of the German Meteorological Society, which met in Braunschweig on June 7 last.—"Astronomy of the Invisible," by Herr Dr. Scheiner. This is the first of a series of articles, and deals, as far as it goes, with the discovery of Neptune by Adams and Le Verrier; it contains also a translation of the letter which Le Verrier wrote to Dr. Galle, who was then an assistant at the Berlin Observatory, telling him the results he had obtained, and asking him to make a search for the unknown planet. As a matter of interest we will give the elements of Neptune as obtained by Le Verrier and Adams, together with the true ones afterwards determined, for the results of such a piece of work will always be looked upon with interest.

	Le Verrier	Adams	True elements
Half major axis	36·15	37·25	30·05
Eccentricity	0·1076	0·1206	0·0090
Longitude of Perihelion	285°	299°	46°
Mass (Sun = 1)	0·0001	0·00015	0·00005
Inclination	0°	0°	1° 8

In the notes two excellent illustrations of parts of the moon are inserted, one being a reproduction of a photograph taken at the Lick Observatory on August 31, 1890, and the other displaying the region to the north of Hyginus, showing these curious river-like appearances as first remarked by Prof. Weinek of Prague. Other notes deal with the astronomical reasons of the Ice Age, observations of Mars during the period 1883–88, polariscope observation of the surface of Venus, &c.

GEOGRAPHICAL NOTES

Mount Orizaba, or Citlaltepetl, in Mexico, has been measured trigonometrically by Mr. J. T. Scovell, with the result that its height is fixed as 18,314 feet. Popocatepetl is about 700 feet lower, and unless Mount St. Elias is found to considerably exceed Russel's estimate of 18,100 feet, Orizaba must be considered the highest summit in North America.

The pumping of brine from the North German salt mines and the consequent subsidence of the land, is the cause of a somewhat interesting change in the small lakes near Mansfeld. The Salzigen See, as observed by Dr. Ule, of Halle, had a maximum depth of thirty metres on June 18, and of no less than forty two metres on June 28, the subsidence of the bottom having taken place at the average rate of more than one metre a day.

Following the death of Dr. Theodor Menke (see p. 302) we have to notice the loss of his fellow-worker, Dr. Karl Spruner von Merz, at the age of eighty-nine. He died on August 24, 1892. After a military career of some distinction, he retired from the army in 1886. His attention was early attracted to historical geography, and his famous "Historical Atlas" (1837–1852) has made his memory imperishable. It was in preparing the third edition of this atlas that he was first associated with Menke.

The camels which were introduced into German South-West Africa last year, have, according to the *Deutsches Kolonialblatt*, proved a great success. They are employed in keeping up communication between Walfisch Bay and Windhoek, and for journeys into the interior. Their power of travelling for a week at a time without food or water has frequently been put to the test on the borders of the Kalahari desert. The climate does not seem to affect them unfavourably, and they have proved exempt from the many fatal diseases which attack horses and even oxen in Namaqualand.

A lecture on "Regions and Races" was delivered on Monday evening in the Regent's Square Hall by Dr. H. R. Mill. The object of the lecture was to demonstrate the continuity of geography with the physical sciences which account for the growth of the surface features of the globe, and with the natural sciences which explain the forms of plant and animal life on its surface. The interactions between man and his environment were discussed as the true basis of the higher geography.

M. J. Thoulet has this summer been engaged in an oceanographical study of the Basin of Arcachon, and publishes in the last number of the *Comptes Rendus* an interesting epitome of his preliminary results. This lagoon forms a valuable oyster preserve, and the researches into the action of the tides on the enclosed water has practical as well as scientific bearings. The investigation will be continued, so as to include the other lagoons along the coast enclosed by sand dunes, and more or less cut off from the sea.

THE COMPARATIVE PHYSIOLOGY OF RESPIRATION[1]

Among the very first of the physiological acts observed were those of respiration. The regular movements of breathing, from the first feeble efforts of the new-born babe until the sigh in the last breath of the dying—after which is silence, cold, and dissolution—have commanded the attention and claimed the interest of every one, the thoughtful and the thoughtless alike. And one comes to feel that in some mysterious way "the breath is the life." But in what way does breathing subserve life or render it possible? Aristotle and the naturalists of the olden time supposed that it was to cool the blood that the air was taken into the lungs, and, as they supposed, also into the arteries. With the limited knowledge of anatomy in those early days, and the fact that after death the arteries are wholly or almost wholly devoid of blood, while the veins are filled with it, what could be more natural than to suppose that the arteries were vessels for the cooling air? If one supposes that he has entirely outgrown this view of Aristotle, let him think for a moment how he would express the fact that an individual is descended from the Puritans, for example. In expressing it even the physiologist could hardly bring himself to say other than "he has the blood of the Puritans in his veins." Would he say "he has the blood of the Puritans in his arteries"?

As observation increased the cold-blooded animals were more carefully studied and found to possess also a respiration; they certainly do not need it to cool the blood. Then there are the insects and the other myriads of living forms that teem in the oceans, lakes, rivers, and even in the wayside pools. Do these, too, have a breath? And the plants on the land and in the water, is the air vital to them? Aristotle and the older naturalists could not answer these questions. To them, on the respiratory side at least, all life was not in any sense the same. It was not till chemistry and physics were considerably developed, not until the air-pump, the balance, and the burette were perfected that it was possible to give more than a tentative answer. It was not, until the microscope could increase the range of the eye into the fields of the infinitely little, possible to form even an approximately correct conception. The first glimmerings of the real significance of respiration for all living things was in the observation that the air which would not support a flame, although it might be breathed, could not support life. That is, there must be something in the transparent air that feeds the flame and becomes the breath of life, the real *pabulum vitæ*, the merely mechanical action of the air not being sufficient.

Since the experiments on insects and other animals by Boyle (1670) with the air pump, by Bernouilli, on subjecting fishes to water out of which all the air had been boiled, and those of Mayow (1674), it became more and more evident that respiration was not confined to the higher forms, but was a universal fact in the organic world. Then came the most fruitful discoveries of all, made by the immortal Priestley (1775–6), viz., that the air is not an element, but composed of two constituents—nitrogen, which is inert in respiration, and oxygen, which is the real vital substance of the air, the substance which supports the flame of the burning candle and the life of the animal as well.

What would seem more simple at this stage of knowledge

[1] Address delivered, in August, 1892, at the meeting of the American Association for the Advancement of Science, by Prof. Simon Henry Gage, of Cornell University, Ithaca, N.Y., Vice-President of the Biological Section.

than that the parallel between the burning candle and the living organism should be thought to represent truly the real conditions? That as the candle consumes the oxygen, burns, and gives out carbon dioxide, so the living thing breathes in oxygen, and gives out in place of that consumed carbon dioxide And as in each case heat is produced, what would be more natural than to look upon respiration as a simple combustion? This was the generalization of Lavoisier (1780-89) As he saw it, the oxygen entered the lungs, reached the blood, and burned the carbonaceous waste there found, and was immediately given out in connection with the carbon with which it had united, and as the gas given off in a burning candle makes clear lime water turbid, so the breath produces a like turbidity

But here, as in many of the processes of nature, the end products or acts were alone apparent, and while the fundamental idea is probably true that respiration is, in its essential process, a kind of combustion or oxidation, yet the seat of this action is not the lungs or blood If the myriads of microscopic forms are considered, these have no lungs, no blood, and many of them even no organs, they are, as has been well said, organless organisms, and yet every investigation since the time of Vinci and Von Helmont, Boyle and Mayow, has rendered it more and more certain that every living thing must in some way be supplied with the vital air or oxygen, and that this is in some way deteriorated by use, and the nearer investigation approaches to the real life stuff or protoplasm, it alone is found to be the true breather, the true respirer, as was shown long ago by Spallanzani (1803-7) If one of the higher animals, as a frog, is decapitated and some of its muscle or other tissue exposed in a moist place, it will continue to take up oxygen and give out carbon dioxide, thus apparently showing that the tissues of the highly organized frog, may, under favourable conditions, absorb oxygen directly from the surrounding medium, and return to it directly the waste carbon dioxide This shows conclusively that it is the living substance that breathes, and the elaborate machinery of lungs, heart, and blood-vessels, are only to make sure that the living matter, far removed from the external air, shall not be suffocated Still more strange, it has been found that if some of the living tissue is placed in an atmosphere of hydrogen or nitrogen entirely devoid of oxygen, it will perform its vital functions for a while, and although no oxygen can be obtained, it will give off carbon dioxide as in the ordinary air If it is asked, "how can these things be?" the answer is apparently plain and direct Not as the oxygen unites directly with the carbon in the burning candle does it act in the living substance The oxidations are not direct in living matter, as in the candle, but the living matter first takes the oxygen and makes it an integral part of itself, as it does the carbon and nitrogen and other elements, and, finally, when energy is to be liberated, the oxidation occurs, and the carbon dioxide appears as a waste product

The oxygen that is breathed to day, like the carbon or the nitrogen that is eaten, may be stored away and represent only so much potential energy to be used at some future time in mental or physical action

So far only living animal substance has been discussed If plants are considered, what can be said of their relations to the air? The answer was given in part by Priestley (1771), who found that air which had been vitiated by animal respiration became pure and respirable again by the action of green plants He thus discovered the harmonizing and mutual action of animals and plants upon the atmosphere, and there is no more beautiful harmony in nature Animals use the oxygen of the air and give to it carbon dioxide, which soon renders it unfit for respiration, but the green plants take the carbon dioxide, retain the carbon as food and return the oxygen to the air as a waste product This is as thoroughly established as any fact in plant physiology, and yet, in his experiments, Priestley had some of what he called "bad experiments", for instead of the plants giving out oxygen and thus purifying the air, they sometimes gave off carbon dioxide, and thus rendered it more impure, after the manner of an animal What investigator cannot sympathize with Priestley when he calls these "bad experiments"; they appeared so rudely to put discord into his discovered harmony of Nature But Nature is infinitely greater than man dreams The "bad experiments" were among the most fruitful in the history of scientific discovery. Ingenhausz (1787) followed them up, carefully observing all the conditions, and found that it was only in daylight that green plants gave out oxygen, in darkness or insufficient light they conducted themselves like animals, taking up oxygen and giving out carbon dioxide Finally it was proved by Saussure (1804) and others that for green plants, and those without green, like the mushroom, oxygen is as necessary for life as for animals It thus became evident that this use of oxygen and excretion of carbon dioxide was a property of living matter, and that the very energy that set free the oxygen of the carbon dioxide was derived from oxidations in the green plant comparable with those giving rise to energy in animals Further that the purification of the air by green plants in light is a separate function—a chlorophyll function as it has been happily termed by Bernard—and resembles somewhat digestion in animals, the oxygen being discarded as a waste product Indeed so powerful is the effort made to obtain oxygen for the life processes by some of the lowest plants—the so called organized ferments—that some of the most useful and some of the most deleterious products are due to their respiratory activity In alcoholic fermentation, as clearly pointed out by Pasteur and Bernard, the living ferment is removed from all sources of free oxygen, and in the effort for respiration the molecules of the sugar are decomposed or rearranged and a certain amount of oxygen set free

It has been found that the motile power of some bacteria like *Bacterium termo* depends on the presence of free oxygen in the liquid containing them When this is absent, they become quiescent This fact has been utilized by Engelmann and others in the study of the evolution of oxygen by green and other coloured water plants The bacteria serving as the most delicate imaginable oxygen test, so that when the minutest green plant is illuminated by sufficient daylight, the previously quiescent bacteria move with great vigour and surround it in swarms Out of the range of the plant, the bacteria are still, or move very slowly, as if to conserve the minute energy developing substance they have in store until it can be used to the best advantage

May we not now approach the problem directly, and answer for the whole organic living world the question, "What is respiration?" by saying it is the taking up of oxygen and the giving out of carbon dioxide by living matter? This is the universal and essential fact with all living things, whether they are animals or plants, whether they live in the water or on land But the ways by which this fundamental life process is made possible, the mechanisms employed to bring the oxygen in contact with the living matter, and to remove the carbon dioxide from it, are almost as varied as the groups of animals, each group seeming to have worked out the problem in accordance with its special needs It is possible, however, in tracing out these complex and varied methods and mechanisms, to discover two great methods—the Direct and the Indirect

In the first, there is the direct assumption of oxygen from the surrounding medium, and the excretion of carbon dioxide directly into it The best examples of this are presented by unicellular forms like the amœba, where the living substance is small in amount, and everywhere laved by the respiratory medium But as higher and higher forms are destined to appear, evidently the minute, organless amœba could not in itself realize the great aim toward which Nature was moving There must be an aggregation of amœbas, some of them serving for one purpose and some for another Like human society, as civilization advances, each individual does fewer things, becomes in some ways less independent, but in a narrow sphere acquires a marvellous proficiency Or, to use the technical language of science, in order to advance there must be aggregation of mass, differentiation of structure, and specialization of function Evidently, however, if there is an aggregation of mass, some of the mass is liable to be so far removed from the supply of oxygen, and the space into which carbon dioxide can be eliminated, that it is liable to be starved for the one and poisoned by the other Nature adopted two simple ways to obviate this—first to form its aggregated masses in the form of a network or sponge, with intervening channels through which a constant stream of fresh water may be made to circulate, so that each individual cell of the mass could take its oxygen and eliminate its carbon dioxide with the same directness as its simple prototype, the amœba

But in the course of evolution forms appeared with aerial respiration, and the insects, among these, solved the mechanical difficulty of respiration by a most marvellous system of air-tubes, or tracheæ, extending from the free surface, and therefore from the surrounding air, to every organ and tissue By means of this intricate network, air is carried and supplied almost directly to every particle of living matter The respiration is not quite

direct with the insects, however, for the oxygen and carbon dioxide must pass through the membranous wall of the air tube before reaching or leaving the living substance.

In the next and final step, the step taken by the highest forms, the living material is massed, giving rise not only to animals of moderate size, but to the huge creatures that swarm in the seas or walk the earth, like the elephant. With all of these the step in the differentiation of the respiratory mechanism consists in the great perfection of lungs or gills, and in the addition of a complicated circulatory system with a respiratory blood, one of the main purposes being, as the name indicates, to subserve in respiration by carrying to each individual cell in the most remote and hidden part of the body the vital air, and in the same journey removing the poisonous carbon dioxide.

This has been called Indirect Respiration, because the living matter of the body does not take its oxygen directly either from air or water, but is supplied by a middleman, so to speak.

The complicated movements by which water is forced over the gills, or by which the lungs are filled and emptied, and the great currents of blood are maintained – that is, the striking and easily observed phenomena of respiration are thus seen to be only superficial and accessory, only serve as agents by which the real and the essential processes, that go on in silence and obscurity, are made possible.

So far I have attempted to give a brief *résumé* of the views on respiration that have been slowly and laboriously evolved by many generations of physiologists, each adding some new fact or correcting some misconception, and I trust that this brief sketch has recalled to your minds the salient facts in our knowledge of respiration, and that it will give a just perspective, and enable me, if I may be permitted, to briefly describe what I believe to be my own contribution to the ever accumulating knowledge of this subject.

In 1876–77, Prof. Wilder, who may be said to have inherited his interest in the ganoid fishes directly from his friend and teacher, Agassiz, who first recognized and named the group, was investigating the respiration of the forms Amia and Lepidosteus, common in the great lakes and the western rivers. As his assistant it was my privilege to aid in the researches, and to acquire the spirit and methods, as in no other way is it so readily possible, by following out, from the beginning to its close, of an investigation carried on by a master. The results of that investigation were reported to this section in 1877, and formed a part of the proceedings for that year. From that time till the present the problems of respiration in the living world have had an ever increasing fascination for me, and no opportunity has been lost to investigate the subject. The interest was greatly increased by the discovery that a reptile—the soft-shelled turtle—did not conform to the generalizations in all the treatises and compendiums of zoology, which state with the greatest definiteness that all reptiles, without exception, are purely air-breathing, and throughout their whole life obtain their oxygen from the air and never from the water. The American soft shelled turtles, at least, do not conform to this generalization, but on the contrary, naturally and regularly breathe water like a fish, as well as air like an ordinary reptile, bird, or mammal.

In carrying on the investigation of the respiration of the turtle, there appeared for solution the general problem, which, briefly stated, is as follows. In case an animal breathes both air and water, or more accurately, has both an aerial and an aquatic respiration, like the ganoid fishes, Amia and Lepidosteus, like the soft shelled turtles, the tadpoles, and many other forms, what part of the respiratory process is subserved by the aqueous and what by the aerial part of the respiration? So far as I am aware this problem had not been previously considered. It was apparently assumed that there were in these fortunate animals two independent mechanisms, both doing precisely the same kind of work—that is, each serving to supply the blood with oxygen and to relieve it of carbon dioxide, as though the other was absent. That was a natural inference, for with many forms the respiration is wholly aquatic, all the oxygen employed being taken from the water, and all the carbon dioxide excreted into it. On the other hand, in the exclusively air-breathing animals, as birds and mammals, the respiration is exclusively aerial.

This natural supposition was followed in the first investigations on the *respiration of the soft shelled turtles*, and while it was proved with incontestable certainty that they take oxygen from the water like an ordinary fish—that is, have a true aquatic respiration, in addition to their aerial respiration—there was altogether too much carbon dioxide in the water to be accounted for by the oxygen taken from it. Furthermore, upon analyzing the air from the lungs of a turtle that had been submerged some time the oxygen had nearly all disappeared, and but very little carbon dioxide was found in its place, while, as compared with human respiration, for example, a quantity of carbon dioxide nearly as great as that of the oxygen which had disappeared should have been returned to the lungs. Likewise in Professor Wilder's experiments with Amia, to use his own words: "Rather more than one per cent. of carbon dioxide is found in the normal breath of the Amia, but much more of the oxygen has disappeared than can be accounted for by the amount of carbon dioxide." Everything thus appeared anomalous in this mixed respiration, and instead of a clear, consistent, and intelligible understanding of it, there seemed only confusion and ambiguity. Truly these seemed like "bad experiments."

It became perfectly evident that the first step necessary in clearing the obscurity was to separate completely the two respiratory processes, to see exactly the contribution of each mechanism to the total respiration. But this was no easy thing to do. In the first place, the animal must be confined in a somewhat narrow space in order that air and water, which are known to have been affected by its respiration, may be tested to show the changes produced in it by the respiratory process; in the second place, the water has so great a dissolving power upon carbon dioxide that even if it were breathed out into the air it would be liable to be absorbed by the water. Then some means must be devised to prevent the escape of the gases from the water as their tension becomes changed; and, finally, the animal in the water must be able to reach the air. A diaphragm must be devised which would prevent the passage of gases between the air and the water, and at the same time offer no hindrance to the animal in projecting its head above the water. As a liquid diaphragm must be used, it occurred to me that some oil would serve the purpose, but the oil must be of peculiar nature. It must not allow any gases to pass from air to water, or the reverse; it must not be in the least harmful or irritating to the animal under experimentation, and, finally, it must itself add nothing to either air or water. Olive oil was thought of, and later the liquid paraffins. The latter were found practically impervious to oxygen and fulfilled all the other requirements, but unfortunately they absorb a considerable quantity of carbon dioxide. Pure olive oil was finally settled upon as furnishing the nearest approximation to the perfect diaphragm sought.[1]

The composition of the air being known, and a careful determination of the dissolved gases in the water having been made, the animal was introduced into the jar and the water covered with a layer of olive oil from ten to fifteen millimetres thick. The top of the jar was then vaselined, and a piece of plate glass pressed down upon it, thus sealing it hermetically. Two tubes penetrate this plate glass cover, one connecting with the overlying air-chamber and the other extending into the water nearly to the bottom of the jar. As the water and air are limited in quantity, the shorter the time in which the animal remained in the jar the more nearly normal would be the respiratory changes; the experiment was continued only so long—one or two hours—as was found necessary to produce sufficient change in the air and the dissolved gases of the water to render the analyses unmistakable.

Proceeding with the method just described, the results given in the following table were obtained:—

Table of Mixed Respiration, showing the number of cubic centimetres of oxygen removed from air and water, and the amount of carbon dioxide added to the air and the water.

	Oxygen from air	Oxygen from water	Carbon Dioxide to air	Carbon Dioxide to water
Ganoid Fish (*Amia calva*)	65	10	22	53
Tadpoles (*Larval Batrachia*)	70	5	24	51
Soft shelled Turtle (*Amyda mutica*)	31	8	10	29
Bull Frog (*Rana catesbiana*)	183	4	110	77

NOTE.—The oxygen from both the water and the air, and the carbon dioxide in the air, were determined with exactness in all the experiments; but owing to the failure of some steps in the titration for the carbon dioxide in the water, the figures given for the Amia and the soft-shelled turtle are the calculated results, assuming that the respiratory quotient is one, as that is the relation found by analysis in the other cases.

[1] See Wm. Thörner on the use of olive oil for the prevention of the absorption of carbon dioxide. Repertorium der analytischen Chemie, 1885, pp. 15 17.

It requires but a glance at the figures in this table to see that the aerial differs markedly from the aquatic part of the respiration Even in the frog, in which the skin forms the only aquatic respiratory organ, the tendency is marked The law appears to be unmistakably this, viz that in combined aquatic and aerial respiration, the aerial part is mainly for the supply of oxygen and the aquatic part largely for the excretion of carbon dioxide This law, which I stated in 1886, has been confirmed by the repetition of old experiments and by many new ones made during the present summer It is also confirmed by the experiments made on Lepidosteus in a different way by Dr E L Mark, and published in 1890. I therefore feel that this is the expression of a general law in nature

From the standpoint of evolution we must suppose that all forms originated from aquatic ancestors, ancestors whose only source of oxygen was that dissolved in the water As the water is everywhere covered with the limitless supply of oxygen in the air, there being 209 parts of oxygen in 1000 parts of air as contrasted with the 6 parts of oxygen dissolved in 1000 parts of water, it is not difficult to conceive that in the infinite years the animals found by necessity and experience that the needed oxygen was more abundant in the overlying air, and that some at least would try more and more to make use of it And as any thin membrane with a plentiful blood supply may serve as a respiratory organ to supply the blood with oxygen, it is not impossible to suppose that such a membrane, as in the throat, could modify itself little by little with ever increasing efficiency, and that a part might become especially folded to form a gill and another might become sacular or lung-like to contain air While I am no believer in the purely mechanical physiology which sees no need of more than physics and chemistry to render possible and explain all the phenomena of life, yet it is patent to every one that, although vital energy is something above and beyond the energies of physics and chemistry, still it makes use of these, and certainly dead matter forms the material from which living is built. So given a living thing, it, in most cases, moves along lines of least, rather than of greatest, resistance, therefore if practically a limitless supply of oxygen may be obtained from the air and only a limited amount from the water, if anything that might serve as a lung is present, most naturally it (the animal) will take the oxygen from the air where it is in greatest abundance and most easily obtained On the other hand, carbon dioxide is so soluble in water that practically a limitless amount may be excreted into it, and as it is apparently somewhat easier, other things being equal, for it to pass from the liquid blood to the water than to the air, it seems likewise natural that the gills should serve largely for the excretion of the carbon dioxide into the water This is the actual condition before us in these, and I believe in all other cases, of mixed or of combined aerial and aquatic respiration And I believe, as stated above, that it may be laid down as a fundamental law in respiration that wherever both water and air are used with corresponding organs—gills for one and lungs for the other—that the aerial part of the respiration is mainly for the supply of oxygen, and the aquatic part largely for the getting rid of carbon dioxide

It is not difficult to see in an actual case like that of the Ganoid Fishes (Amia and Lepidosteus) the logical steps in its evolution, by which this most favourable condition has been reached A condition rendering these fishes capable of living in waters of almost all degrees of purity, and thus giving them a great advantage in the struggle for existence But what can be said of the soft-shelled turtles, animals belonging to a group in which purely aerial respiration is almost exclusively the rule? Standing alone, this might be exceedingly difficult or impossible of explanation The Batrachia (frogs, toads, salamanders, &c) all have gills in their early or larval stage, and most of them develop in the water, and are in the beginning purely aquatic animals. The adults must therefore, in most cases, repair to the water at the spawning season and frequently in laying the eggs they must remain under the water for considerable intervals Being under the water, and the need of oxygen becoming pressing, there seems to be, by a sort of organic memory, a revival of the knowledge of the way in which respiration was accomplished, when, as larvæ, their natural element was water, and they take water into the mouth and throat This may be done by as highly a specialized and purely aerial form as the little brown tree-frog (*Hyla pickeringii*) or the yellow spotted salamander (*Amblystoma punctatum*) Another very interesting form, the vermilion-spotted newt (*Diemyctylus*), after two or three years of purely aerial existence goes to the water on reaching maturity and remains there the rest of its life, regularly breathing both by its lungs and by taking water into its mouth and throat A still more striking example is given by Prof Cope The young siren almost entirely loses its gills, and later regains them, becoming again almost completely aquatic in its habits as in the larval stage

With these examples, which may be seen by any one each recurring year, is it impossible or difficult to conceive that in the struggle for existence the soft shelled turtles found the scarcity of food, the dangers and hardships on the land greater than those in the water? Or, remaining constantly in the water, and advantageously submerged for most of the time, it gradually reacquired the power of making use of its pharyngeal membrane for obtaining oxygen from the water and excreting carbon dioxide into it as had its remote ancestors And further, is it not intelligible that with capacious lungs, which it can fill at intervals with air containing so large a supply of oxygen that it, like the other double or mixed breathers, should use its lungs to supply most of the oxygen and its throat to get rid of much of the carbon dioxide?

Indeed it seems to me that if the evolution doctrine is a true expression of the mode of creation, then development may be in any direction that proves advantageous to an organism, even if the development is a reacquirement of long discarded structures and functions

In closing may I be permitted to say to the older biologists—to those familiar with the encouragements and inspirations that come with original investigation, that I trust they will pardon what to them is unnecessary personality or excess of detail in this address, for the sake of the younger ones among us, to whom the uphill road of research is less familiar Judging from my own experience in listening to similar addresses by my honoured predecessors, it is helpful to know, when one is beginning, something of the "dead work," the difficulties and discouragements, as well as the triumphs, in the advancement of science

MINES AND MINING AT THE CHICAGO EXHIBITION

THE exhibition of objects relating to mines and mining at the "World's Fair" promises to be one of exceptional interest and importance The following details about it were given by Mr George F Kunz in a paper read before the recent meeting of the American Association for the Advancement of Science —

The building of mines and mining, which is entirely completed, is 700 feet long and 350 feet wide, at an elevation of 25 feet above the main floor On both sides is a gallery 60 feet wide, running the entire length of the building Up to the present time there have applied for space in this building 26 foreign Governments and 36 States, these exhibits to be supplemented by other State and Government exhibits, such as that of Sweden in the Swedish building, the East Indian in the East Indian court, Illinois in their State building, &c

There will be a scientific collection of all the known elements, and with them a complete collection of all the known alloys of gold, silver, copper, zinc, tin, &c , such as electrum, German silver, Babbits metal, fusible metal, and the thousand and one other, common and rare, used in the arts and industries In the name of the Lake Superior copper mines, Prof Alex Agassiz has promised a complete exposition of ores, rocks, and processes, illustrating the occurrence mining, metallurgy of copper There is now in preparation a coal collection to contain all varieties of coal, from every known occurrence in the United States Petroleum will be shown as it never has been at any exhibition The subject of abrasives of all kinds will form a special exhibit under the charge of Mr T Dunkin Paret, who has devoted his entire life to this subject, and is now making a special European trip to enlist the co operation of foreign manufacturers and investigators to supplement the American exhibit

The De Beers Mining Company of South Africa, who own and control more than 95 per cent of the entire diamond output, will make first a full and comprehensive exposition of diamond mining and the original blue stuff, a decomposed peridotite, enclosing carbonaceous shale, the matrix of the diamond, in great quantities They will show it passing through

the various washing machines, and every process separating the diamond from the matrix, in which exists a percentage of 1 carat 205 milligrams in a load of 1600 pounds There will be a case containing over 10,000 carats of diamonds of all colours and of the various qualities, with a full series of the associated minerals and rocks Every stage of the cutting and polishing of the diamond will be represented

Nearly every mineral dealer in the United States has applied for space, and from the foreign trips and other preparations it is very evident that in the line of cabinet specimens and educational minerals the assembled collections will exceed those of any other exposition in importance

One of the large gallery halls will contain a reference library for the use of visitors This it is hoped will be a very comprehensive exposition of the literature of the subject of mines, mining, geology, and mineralogy This is to be supplemented by historical portraits, documents, and other allied material

An early history of mining and mining processes will be shown, starting with stone hammers and other aboriginal implements found in the copper mines of Lake Superior and the turquoise mines of New Mexico, the old Mexican Pateo, to the most improved modern methods, and the remarkable sectional and glass models of mines, prepared by eminent mining engineers, used in the great mining lawsuits to prove their arguments

One of the large corridor rooms in the gallery has been offered to the American Institute of Mining Engineers for their own use as a headquarters during the Exposition They in turn may extend the courtesy to mechanical and civil engineers, as well as the English, German, French, and other foreign engineers whose hospitality they enjoyed in 1889 There is every reason to believe that at least from 800 to 1000 foreign engineers will visit the Exposition

If only three fourths of the promised exhibits are received, and there is every assurance that there will be many more coming, it may be safely said, even now, that the mining, metallurgical, geological, and mineralogical exhibits of the Columbian World's Fair will exceed in scientific importance and in extent the combined exhibits of the Centennial, the 1878, 1889, the Paris and the Vienna Expositions, at least two fold

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —Lord Walsingham, the High Steward of the University, has expressed his wish to give annually for three years a gold medal for the best monograph or essay giving evidence of original research in any subject coming under the cognizance of the Special Board for Biology and Geology The offer having been accepted and the regulations for the medal having been approved, the Special Board for Biology and Geology give notice that the medal is offered for competition for the second time during the ensuing academical year The essays are to be sent to the chairman of the Special Board (Prof Newton, Magdalene College) not later than October 1, 1893

The regulations for the medal are published in the *Cambridge University Reporter*, No 908 (November 17, 1891), p 186

Sir R S Ball, Lowndean Professor, will give his inaugural lecture in the Anatomical Theatre on Friday, October 21, at noon

Dr Cayley, Sadlerian Professor of Mathematics, resigns his place on the Council of the Senate on October 25

The Council of the Senate recommend that the University of the Cape of Good Hope should be affiliated to Cambridge, on the same terms as those granted to New Zealand

LONDON —Four lectures upon "The Sun in its Relation to the Universe of Stars" will be delivered in Gresham College, at six p m on the evenings of October 25, 26, 27, and 28, 1892, by the Rev Edmund Ledger

SCIENTIFIC SERIALS

The Journal of the Royal Agricultural Society of England, 3rd Series, Vol iii, pt 3 —Allotments and Small Holdings, by Sir J B Lawes and Dr Gilbert The authors have collected statistics relating to Allotments and Small Holdings in Great Britain They point out that "within the present century there has been a great reduction in the number both of owners and of occupiers of farms not exceeding 50 acres in area, such as it seems to be the object of the promoters of the Small Holdings Act of 1892 greatly to increase" After noticing the Rothamstead Allotments they proceed to discuss the conditions essential to the success of small holdings, and they conclude that ordinary rotation farming is much less suitable for small holdings than dairy farming, the production of poultry and eggs, and market gardening when favourable conditions exist, the authors do not believe, however, that the system of small holdings will materially check the influx of agricultural labourers into the towns This number of the *Journal* also contains a short article by W H Hall on Small Holdings in France Mr Hall is "convinced that small holders (in England) have a great future before them as soon as they can be educated up to producing such articles as require to be consumed fresh, and will not bear long carriage" This last clause contains the key of the whole matter —On the Vermin of the Farm, pt. ii, by J E Harting In this paper the author has much to say in defence of the mole (*talpa europæa*), and of the weasel (*mustela vulgaris*), there is little but condemnation, however, for the hedgehog, the stoat, and the polecat, the last mentioned animal is now hardly known to most people, though the domesticated variety (the ferret) is common -The Warwick Meeting of 1892, by Dr Fream, Official Reporter This report shows the meeting to have been a good average one, except in the attendance of visitors on the last two days Judge's reports show that in many cases the quality of the exhibits of live stock was far above the average.—Miscellaneous Implements Exhibited at Warwick, by T H Thursfield —The Farm Prize Competition of 1892, by J B Ellis —Among the shorter articles is one deserving of careful attention, entitled New Modes of Disposing of Fruit and Vegetables, by Chas Whitehead, in which are discussed the "evaporating" and the "canning" of fruit, methods already in use in Queensland are described and discussed with reference to their adoption in this country when prices for fresh fruit are low —Dr J W Leather contributes a short article upon his method of detecting and estimating "castor-oil seeds in cattle foods" A weighed quantity of the suspected food is digested with hot dilute sulphuric acid (or HCl, about 2 p c.) for half an hour, washed free from acid, re-digested with a hot dilute solution of caustic soda, washed, and then finally treated with a quantity of bleaching powder The husks of all seeds other than castor oil seeds are bleached by this treatment, and any unbleached husks can be picked out and weighed

Wiedeman's Annalen der Physik und Chemie, No 9 —The principle of least effect in electrodynamics, by H von Helmholtz —On the differences of potential of chains with dry solid electrolytes, by W Negbaur —On the reciprocity of electric osmose and flow currents, by U Saxen —Resonance phenomena and absorptive capacities of metals for the energy of electric waves, by V Bjerknes —Objective presentation of the Hertzian experiments with rays of electric force, by L Zehnder —Dispersion and absorption of light according to the electrical theory of light, by D A Goldhammer —On the measurement of high temperatures, by L Holborn and W Wien The apparatus was a modification of Le Chatelier's thermo-element, consisting of a combination of platinum and a platinum-rhodium alloy This was calibrated by placing it inside the porcelain vessel of an air-thermometer and comparing the readings, different thermo couples were compared by exposing together in short porcelain tubes, two branches being welded together The following fusing temperatures were deduced gold 1072°, silver 968°, copper 1082° —On the expansion of gases at low pressures, by G Melander Working with pressures ranging from 770 to 4mm, and temperatures from 0° to 100°, the gases being kept at constant volume, the supposed law of constant decrease of coefficient of expansion with decreasing pressure was found not to hold good. That of air decreases down to 232mm, where it is 0 003659, and then increases. That of carbon dioxide decreases down to 76mm, after which it increases, whilst that of hydrogen increases steadily —Specific gravity and heat of fusion of ice, by J v Zakrzevski The apparatus was a very delicate form of Bunsen's ice calorimeter The specific gravity of ice at −0 701° C was found to be 0 916710 The cubical coefficient of expansion at that temperature was 0 000077, which gives for the sp gr of ice at 0° C the value 0 916660 —On the theoretical conceptions of Georg Simon Ohm, by K. Von der Mühll —Variation of the specific volume of sulphur with the temperature, by M Toepler.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 16.—"Thermal Radiation in Absolute Measure." By Dr. J. T. Bottomley, M.A., F.R.S.

The paper contains an account of an experimental investigation by the author in continuation of researches on the same subject which have been already published (Roy. Soc. Proc., 1884, and Phil. Trans., 1887). In the earlier experiments metallic wires heated by an electric current were used. The loss of heat from a heated body, however, depends to some extent on the form and dimensions of the body; and it seemed important to experiment on the loss of heat from bodies differing in form from the wires already used, and larger in dimensions.

Accordingly, two copper globes used by Mr. D. Macfarlane in 1872 (Roy. Soc. Proc., 1872, p. 93) were employed for a new series of experiments.

After preliminary experiments (using the same enclosure which Macfarlane employed and with the surfaces of Macfarlane's globes prepared in four different ways) new apparatus was constructed. The object was to experiment both with full air pressure and with different amounts of exhaustion of the air, and Macfarlane's enclosure is unsuitable for this purpose.

In the arrangement adopted, the heated globes were hung at the centre of a hollow metallic sphere, which was connected with the Sprengel pump and surrounded with cold water, and were allowed to cool. The temperature of the cooling globe was read off at equal intervals of time by means of a thermo-electric junction; and from these readings the absolute loss of heat per unit of cooling surface, per unit difference of temperatures of surface and surroundings, per unit of time, is calculated.

The details of the apparatus and method of experimenting are given in the paper. It is enough to say here that the globes were used with their surfaces in two different conditions:—(1) Thinly coated with lamp-black, and (2) silvered and brightly polished; and in both conditions the absolute loss of heat, both in air and in vacuum more or less complete, was determined. The tables and curves attached to the paper give the details of the results.

To quote one or two examples:—With the sooted surface a total loss of heat by convection and radiation of 3.42×10^{-4} c.g.s. units per square centimetre, per second, per 1° C. of difference of temperatures of globe and surroundings, was observed with a difference of temperatures of 100° C., and with the surroundings at about 14° C. Under similar circumstances the radiation in vacuum of $\frac{1}{2}$M (half-a millionth of atmospheric pressure of non-collapsible gas) was about 1.40×10^{-4}.

Taking a silvered and brightly-polished surface under the same circumstances, the loss in full air was 2.30×10^{-4} c.g.s., and with the highest vacuum and brightest polish obtained, it was reduced 1.80×10^{-5}, with in this case a difference of temperatures of 180° C. The loss with 100° C. difference would be considerably less, but is not known experimentally at present.

The author returns thanks to Mr. James H. Gray, M.A., B.Sc., for excellent assistance given; and expresses himself most deeply indebted, both for assistance in experimenting and calculating of the results, and for most valuable and ingenious aid of various kinds during the course of this work, to his friend Mr. A. Tanakadate, now Professor in Tokio, Japan.

Entomological Society, October 5.—Henry John Elwes, vice-president, in the chair.—Mr. C. O. Waterhouse exhibited a specimen of *Latridius nodifer* feeding on a fungus, *Trichosporium roseum*.—Mr. McLachlan, F.R.S., exhibited a male specimen of *Elenchus tenuicornis*, Kirby, taken by the Rev. A. E. Eaton, on August 22 last, at Stoney Stoke, near Shepton Montague, Somerset, and described by him in the *Entomologist's Monthly Magazine*, October 1892, pp. 250-253. Mr. McLachlan stated that another specimen of this species had been caught about the same date in Claygate Lane, near Surbiton, by Mr. Edward Saunders, who discovered that it was parasitic on a homopterous insect of the genus *Liburnia*, and had also described it in the *Entomologist's Monthly Magazine*.—Mr. J. M. Adye exhibited, for Mr. McRae, a large collection of *Colias edusa*, *C. edusa* var. *helice*, and *C. hyale*, all taken in the course of five days' collecting in the neighbourhood of Bournemouth and Christchurch, Hants. There were twenty-six specimens of *helice*, some of which were remarkable both in size and colour. He stated that Mr. McRae estimated the proportion of the variety *helice* to the type of the females as one in fifty. Mr. Adye also exhibited two specimens of *Deiopeia pulchella*, recently taken near Christchurch. Mr. Hanbury, Mr. Jenner Weir, and Mr. Merrifield commented on the interesting nature of the exhibition and on the recent extraordinary abundance of *C. edusa* and the var. *helice*, which was probably not exceeded in 1877.—Mr. Dallas Beeching exhibited four specimens of *Plusia moneta*, lately taken in the neighbourhood of Tunbridge Wells.—Mr. H. Goss exhibited, for Mr. Gervase F. Mathew, two *Plusia moneta* and their cocoons, which were found at Frinsted, Kent, on September 3 last. It was stated that Mr. Mathew had found seven cocoons on the under side of the leaves of monkshood, but that the imagos had emerged from five of them.—Mr. Rye exhibited a specimen of *Zygæna filipendulæ* var. *chrysanthemi*, and two varieties of *Arctia villica*, taken at Lancing, Sussex; also varieties of *Coccinella ocellata* and *C. oblongoguttata* from Oxshott.—Mr. A. H. Jones exhibited specimens of *Argynnis pales* var. *isis*, and var. *arsilache*, the females of which showed a tendency to melanism, recently taken in the Upper Engadine; also melanic forms of *Erebia melampus*, and a specimen of *Erebia nerine*.—Mr. Elwes exhibited specimens of typical *Erebia melas*, taken by himself in the Western Tyrol, on July 25 last, at an elevation of 7000 feet; also specimens of the same species from Hungary, Greece, and the Eastern and Central Pyrenees. He stated that the absence of this species from the Alps, which had seemed to be such a curious fact in geographical distribution, had been first disproved by Mrs. Nicholl, who discovered it at Campiglio two years ago. He also exhibited fresh specimens of *Erebia nerine*, taken at Riva, on the lake of Garda, at an elevation of about 500 feet; also specimens of the same species, taken at the same time, at an elevation of about 5000 feet, in cool forest glades; and remarked that the great difference of elevation and climate did not appear to have produced any appreciable variation in this species.—Mr. G. T. Porritt exhibited two varieties of *Abraxas grossulariata*, bred during the past summer from York larvæ. Also a curious Noctua taken on the sandhills at St. Anne's on Sea on August 20 last, and concerning which a difference of opinion existed as to whether it was a melanic form of *Agrotis cursoria* or of *Caradrina cubicularis*. Also a small dark form of *Orgyia antiqua*, which had occurred in some numbers at Longridge, near Preston.—Mr. A. Eland Shaw exhibited a specimen of *Mecostethus grossus*, Linn., taken lately at Irstead, in the Norfolk-broad district. He stated that this was the first recorded capture of this species in Britain since 1884.—Mr. C. G. Barrett exhibited a specimen of *Syrichthus alveus*, caught in Norfolk about the year 1860; a beautiful variety of *Argynnis euphrosyne*, caught this year near Godalming; and a series of varieties of *Ennomos angularia*, bred from a female taken at Nunhead.—Mr. P. Crowley exhibited a specimen of *Zygæna filipendulæ* var. *chrysanthemi*, taken last August at Riddlesdown, near Croydon.—Lord Walsingham, F.R.S., sent for exhibition several specimens of larvæ of *Sphinx pinastri*, preserved by himself, which were intended for presentation to the British Museum. The larvæ had been sent to him by Lord Rendlesham, who obtained them from ova laid by a female captured in Suffolk last August.—M. de Nicéville communicated a paper entitled "On the variation of some Indian Euplœas of the subgenus *Stictoplœa*" and Captain E. Y. Watson exhibited, on behalf of M. de Nicéville, the specimens referred to in this paper. Colonel Swinhoe, Mr. Hampson, Mr. E. B. Poulton, F.R.S., and the chairman took part in the discussion which ensued.—Mr. W. Bateson read a paper entitled "On the Variation in the Colours of Cocoons and Pupæ of Lepidoptera; further Experiments."—Mr. Poulton read a paper entitled "Further Experiments upon the Colour relation between certain Lepidoptera and their Surroundings."—Miss Lilian J. Gould read a paper entitled "Experiments on the Colour-relation between certain Lepidopterous larvæ and their surroundings, together with observations on Lepidopterous larvæ." A long discussion ensued, in which Mr. Jenner Weir, Dr. Sharp, F.R.S., Mr. Merrifield, Mr. Poulton, and the chairman took part.

PARIS

Academy of Sciences, October 10.—M. Duchartre in the chair.—M. Emile Picard presented to the Academy the second volume of his "Traité d'analyse."—The University of Padua invited representatives of the Academy at the forthcoming tercentenary celebration of Galileo's accession to his chair at that University.—A decisive blow to the theory of centripetal and ascending motion in cyclones, by M. H. Faye.—The move-

ments of the heart, studied by chronophotography, by M Marey The heart of a tortoise was removed and mounted so that a funnel led into an auricle, and a bent tube out of the ventricle and upwards to the mouth of the funnel The funnel was filled with defibrinated blood, which passed into the auricle and thence into the ventricle When the latter was full, an automatic systole projected the blood upwards through the tube and back into the funnel This process was repeated for several hours after death. It was more minutely studied by taking a series of instantaneous photographs in rapid succession (reproduced), which show the details of the process with great accuracy For actinic purposes, the heart was painted white with water colour The hypothesis of an active diastole of the ventricle was proved to be unfounded —The inhibitory phenomena of the nervous shock, by M H Roger —On the transformation of the equations of Lagrange, by M Paul Painlevé —On a class of curves and surfaces, by M A Pellet On the motion of a thread in space, by M G Floquet —On internal reflection in crystals, by M Bernard Brunhes —A new method of preparation and photometry of the phosphorescent sulphide of zinc, by M Charles Henry It is possible to obtain several pounds at a time of a fine phosphorescent zinc sulphide by the following process Add ammonia to a perfectly neutral solution of pure zinc chloride, redissolve the precipitate in an excess of ammonia, precipitate completely, but without the slightest excess, the ammoniacal oxide of zinc by sulphuretted hydrogen, heat to a white heat in a crucible of refractory earth placed inside a graphite crucible, after having well washed and dried the amorphous sulphide to the exclusion of all impurities. By Mascart's photometer, the intensity of light emitted by a sample of the sulphide in candle metres after saturation was 0·000215 But this value is probably too small —On the antimonites of pyrogallol, by MM H Causse and C Bayard —On the tartaric ethers, by M P Freundler —Volumetric determination of the alkaloids, by M L Barthe —On a new method of brick manufacture, used in certain parts of Central Asia, by M Edouard Blanc This mode of manufacture is practised by the tribes in Western Mongolia, on the frontier of Siberia The extremes of temperature render a brick of great durability a necessity of life This is attained by the use of steam The oven is cylindrical and surmounted by a hemispherical cap, which is kept open for the first three days The bricks, about 7000 at a time, are baked by means of a fire fed by about 7000 kgr of an annual ligneous plant, the *Alhagi Camelorum* On the third day, the opening is closed with felt, which is kept constantly wetted, so that the bricks are enclosed in a steam bath, while kept at a red heat Under these circumstances, some novel chemical reactions appear to take place The bricks, red after the first period, appear dark grey after the second part of the process Their structure appears porous, they become sonorous and acquire a great hardness They show a striking resemblance to certain trachytes Made from the same clay as our bricks, they resist weathering very much better, and have an extraordinary hardness and cohesion —A process for testing the purity of coprah oils and palm oils, by M Ernest Milliau —On the part played by spermine in intra-organic oxidations, by M Alexandre Poehl —On the respiration, transpiration, and dry weight of leaves developed in sunlight and in the shade, by M L. Geneau de Lamarlière —On the structure of the assimilating tissue of the branches in Mediterranean plants, by M William Russell —Experimental study of the action of the humidity of the soil on the structure of branches and leaves, by M Auguste Oger —Contributions to the stratigraphy of the Pyrenees, by MM Roussel and De Grossouvre —On some bombs of Etna, from the eruptions of 1886 and 1892, by MM L Duparc and L. Mrazec.—Meteoric iron recently fallen at Hassi Iekna, in Algiers, by M Stanislas Meunier —Oceanographic observations relating to the basin of Arcachon (Gironde), by M J Thoulet —Vegetation of the lakes of the Jura mountains, by M G Rambault Ant Magnin —M Bischoffsheim, on behalf of Prof Weineck, Director of the Prague Observatory, presented a photograph of the lunar crater Vendelinus

POLAND'S "FUR-BEARING ANIMALS"

Fur-bearing Animals in Nature and Commerce By Henry Poland, F Z S , 1 vol , 8vo (London Gurney and Jackson, 1892)

ALTHOUGH, as civilization spreads with ever-quickening progress over all parts of the world's surface, wild animals necessarily diminish in numbers year by year, few people have any idea of the enormous quantities of furs and pelts still annually imported into the United Kingdom, and of the extent of the commerce in such commodities still carried on Mr Poland's useful treatise on Fur-bearing Animals will afford us much information on this subject In the introduction to his volume full statistics about the past and present condition of the fur-trade are given, and it is stated that at the great fur sales now held at the College Hill sale-rooms in London the annual value of all classes of fur-skins sold is little short of £1,000,000

But it is with the main portion of the present work that naturalists will be most interested, as, so far as we know, this is the first occasion on which a large amount of practical knowledge of the subject has been combined with a certain amount of scientific information Mr Poland takes the fur-bearing animals systematically, mostly, it appears, according to the order and nomenclature employed in the list of animals in the Zoological Society's Gardens, and gives us under each head particulars as to their localities, distribution, coloration, and varieties, together with information as to the quantities of skins imported and the uses to which they are devoted

Beginning with the Quadrumana, we find that the skins of about twenty five Monkeys and Lemurs are used in commerce Of these the most abundant is the "Black Monkey" of Western Africa (*Colobus vellerosus* and other allied species), of which some 90,000 are imported every year Another species of Colobus, the Guereza of Abyssinia and Eastern Africa, also furnishes a "rare and much esteemed skin," of which the value is from 10*s* to 15*s* We may remark that the Tcheli Monkey (*Macacus tcheliensis*) is not from Cochin China, as stated by Mr Poland, but from Mantchuria, north of Pekin, where it ranges further north than any other Monkey now existing There is a fine example of this species at present living in the Zoological Society's Gardens The "China Grey Monkey," described as having a "long white tail," is evidently of quite a different species, the Tcheli Monkey having only a very short caudal appendage

The Carnivora, which next follow, take up the greater part of Mr Poland's volume, nearly 150 species of this extensive group supplying pelts which are more or less useful to mankind Commencing with the larger Cats, our author calls attention to the great difference between the Bengal Tiger and the Mongolian or Chinese variety of the same animal, in which the fur is very thick, often from 1½ to 2 inches in length, and makes a long fringe round the face Skins of the Chinese Tiger are much esteemed on this account, and fetch from £10 to £40 each, according to quality ; whereas a good Bengal Tiger skin may be purchased at about £4 or £5 The Lynx is another of the true Cat-tribe which furnishes a rather important article of trade, the quantity of Lynx-skins imported by the Hudson's Bay Company ranging up to 40,000, and in exceptional years reaching even to 70,000 Coming to the Musteline Carnivora or Weasels, we find the Mink (*Mustela vison*) an animal of still greater importance in trade In 1890 upwards of 360,000 skins of the Mink from North America were sold in London, and converted mostly into muffs On the other hand, an allied species of the same genus, the Ermine (*M erminea*), formerly so much esteemed, and regarded as a princely fur to be devoted exclusively to royalty, is going quite out of fashion "It has become very much neglected and a few years ago was practically unsaleable "

The fur of the Skunk, *Mephitis mephitica*, many persons will be surprised to hear, in spite of its "powerful scent," which "cannot be entirely got rid of," is largely used In 1891 nearly 700,000 skins of it were imported, and worked up into muffs and capes But the prince of furs of this division of the Carnivora is that of the Sea-otter, *Enhydra lutris*, of the north-west coast of America, an animal generally supposed to be almost extinct in consequence of long ages of persecution But 2369 Sea-otter skins were imported by the Alaska Commercial Company and other traders in 1891, and sold at an average price of £57 apiece "The fur is principally consumed in Russia, where it is used for collars of noblemen's coats "

From the Sea-otter we pass by an easy transition to the Fur-seals—a group still of sufficient importance to have brought three of the greatest nations of the world nearly to loggerheads, but in bygone years much more abundant than now From South Georgia in the Antarctic Seas one million two hundred thousand Fur-seal-skins are said to have been taken soon after its discovery, and nearly an equal quantity from Kerguelen Island, but the natural consequence has followed that the animal has become practically extinct in the Antarctic seas. The only species of Otaria that still yields its skin year by year to supply the ladies of Europe and America with "sealskin jackets" is the Alaska Fur seal, *Otaria ursina*, which, owing to the stringent regulations enforced for its preservation, is still abundant in certain parts of the North Pacific According to the best authorities about 4,500,000 of this Fur-seal resort to the Pribylov Islands every breeding season, and until 1890, when the number to be slaughtered was reduced, 100,000 were killed every year. Smaller quantities are obtained from other parts of the North Pacific We need not here go into further details upon this animal which has lately been the subject of so much discussion, except to say that unless even more severe regulations are made for its preservation than those now existing, the Alaska Fur-seal will indubitably share the fate of its Antarctic brethren, and cease to furnish an article of commerce

Of the order Insectivora, which follows the Carnivora, Mr. Poland only mentions two species as supplying fur for the use of mankind These are the Common Mole (*Talpa europæa*) and the Russian Musk-rat or Desman (*Myogale moschata*) The skin of the Mole is so small as to be of little value, but several thousands are collected annually and converted into those most comfortable of garments, moleskin waistcoats The fur of the

Russian Desman (*Myogale moschata*) is sometimes used in this country for mantle-trimmings, but is more appreciated in America. The Desman of the Pyrenees (*M pyrenaica*), which Mr Poland confounds with that of Russia, is a much smaller and quite different animal

We now come to the great group of Rodents, many of which supply their skins in enormous quantities for the benefit of mankind Mr Poland's list contains thirty-three species of this Order The Beaver, formerly of such pre-eminent importance, is now much reduced in numbers, but 63,419 Beaver-skins were sold by the Hudson's Bay Company in 1891 Another Canadian Rodent, the Musquash (*Fiber zibethicus*), still ranges over the "north-west" in enormous armies, from three to four millions of their skins being obtained every year In 1891 the Hudson's Bay Company alone sold 554,104 of them Another much appreciated little animal of the Rodent order is the Chinchilla from the highlands of Chili and Bolivia Its fur, which is remarkably soft and delicate, is principally used in England, France, and America Several allied species of the peculiar South American family *Chinchillidæ* are also called by the general name of "Chinchilla"

Of the Leporidæ or Hare family, which concludes the Rodents, the Polar Hare and the Common Rabbit supply the largest numbers of useful skins Of the Russian or Polar Hare (*Lepus glacialis*)—one of the best-known denizens of Arctic latitudes—from 2,000,000 to 5,000,000 skins are said to be collected annually, mostly in their thick white winter coats But Rabbit-skins are employed in much more enormous quantities Since the great increase of this Rodent in Australia and New Zealand, where, as is well known, the Rabbit has become an awful pest, the number of its skins sent to London for sale from those colonies has increased year by year, until, according to Mr Poland's calculations, from fifteen to twenty millions are now imported Very large numbers of Rabbit skins are also brought to England from France, Germany, and other countries, mostly taken from domestic varieties

The American "Buffalo" (more correctly "Bison") is extinct as regards trade purposes, so that we need not go into the quantities of "Buffalo-robes" formerly imported, which in Catlin's time reached 200,000 in the year; nor will the other species of the order Ungulata, of which Mr Poland gives forty-six in his list as affording skins more or less used in commerce, detain us long The most important of them are the different varieties of the domestic Sheep and Goat, which are spread all over the world and supply mankind with every variety of clothing-materials The extent of this commerce is enormous Of tanned Goatskins alone 7,259,212 were imported into this country in 1891, and 5,613,996 skins of "East Indian Sheep" were sold in London

The Edentates, Marsupials, and Monotremes, with which Mr Poland concludes his volume, are of small importance after the preceding orders "Australian Opossum," however, under which common name are included skins of several different species and varieties of the genus *Phalangista*, forms an exception, as the annual supply of this article exceeds two million skins, which are much appreciated for their "cheapness, light weight, pretty colour, and general usefulness" Of Kangaroos of all sorts over 120,000 skins were imported in 1891, so that, what with these and the Phalangers and its twenty million Rabbit-skins, Australia has a fair share of this lucrative commerce But altogether, no doubt, the Dominion of Canada and adjoining district of Alaska still get the lion's share of the traffic in "furs and pelts"

In concluding our somewhat lengthy notice of Mr Poland's volume we may say that it is replete with information that a zoologist cannot obtain elsewhere in a convenient form, but at the same time contains many errors in the identification of the species, some of which we have pointed out In a second edition, which will doubtless be called for, the author should obtain the assistance of a scientific expert He would also do well to cut out of his list some of the less important species (such as the Dingo, Great Anteater, and Echidna), which are not really used for trade purposes, and to bring up his statistical information under every head to the most recent date

SPINAL NERVE-IMPULSES AND ELECTROMOTIVE CHANGES

The Structure and Functions of the Brain and Spinal Cord By Victor Horsley, B S, F R C S, F R S (Griffin and Co, 1892)

AS stated in the preface, the present volume (being the Fullerian Lectures for 1891) discusses the spinal cord and ganglia alone, and is to be followed by two others, dealing respectively with the brain and with physiological psychology

Most books of this character have to be considered in their relation to two classes of readers—those who are experts in its subject-matter and those who are not—a distinction that applies with special force to the outcome of Royal Institution lectures We shall therefore take two readings of the volume before us

The table of contents and a cursory glance at the text very soon bear out the author's modest remark that these lectures have no pretensions to form a monograph upon the subject of which they treat Nor are they an elementary review of it (in the ordinary sense of these words), but rather a series of vignettes—historical, zoological, and speculative—relating to the nervous system The historical lecture is interesting, the curious and hideous figure on p 13, from a twelfth century manuscript in the Bodleian Library, very aptly fulfils its purpose, viz, to demonstrate that no advance is there apparent upon the ideas of Aristotle Prof Horsley avoids plainly asserting that Sir Charles Bell discovered the sensory and motor functions of the nerve-roots, the statement is implied, not made, at first reading we think it is made, on second reading we recognize that it is not made, on third reading that it is positively implied It is evident that Prof Horsley has read Bell's original pamphlet, "Idea of a New Anatomy of the Brain" (1811);[1] he does not, however, go

[1] Not an easy matter—we only know of one copy in London, that at the British Museum misdated 1802—nor a superfluous matter, as any one knows who has compared the "reprints" of 1824 and of 1830 with the original paper in the Phil Trans. of 1821 on the nerves of the face. Correct reprints of Bell's first paper have been published in "Documents and Dates of Modern Discoveries in the Nervous System," (? by A Walker), London, 1839, and in the "Journal of Anatomy and Physiology" for 1869, by A Shaw

on to say that Bell's two roots (before 1824) were an anterior "cerebral" root, subserving motion and sensation, and a posterior "cerebellar" root serving to govern vital actions. The *principle* of localization in nerve-roots, far more clearly stated by Walker in 1809 and the facts demonstrated by Majendie in 1822, are not alluded to. In the second lecture Kleinenberg's cells are figured and described, and on the next page admitted to be mythical; thus Prof. Horsley is enabled legitimately enough to utilize this time-honoured if anatomically incorrect illustration to enforce the essentially correct principle of differentiation. Lecture III. treats of jelly-fish, star-fish, and cray-fish, with reference to rhythm, "localization" and co-ordination of movements. "Localization" is used as a term to denote a physiological property or function (pp. 48-49), *i.e.*, as used by psychologists to denote an act of the subject, rather than as used by physiologists to indicate observed relations between parts and functions. This use of the word is perfectly legitimate, but it is rather apt to create confusion of thought. "Localization" is sometimes used in a similar sense in relation to brain-function, and with a similar inconvenience. "localization" *by* the brain in a psychological sense is properly localization by the subject, localization *in* the brain is an object of physiological experiment. No doubt it may be said that psychological localization rests upon physiological differentiation and localization; none the less the use of the term to denote a physiological property or function is not advisable without very careful definition. Lecture IV. deals with vertebrates: nerve-fibres, gullet theory of canalis centralis, spinal cord, and nerve-roots. Lecture V. with ganglia. Here we must criticise. Looking to the class of readers addressed, Fig. 26 may be misleading as regards the anatomy of anterior and posterior roots. Fig. 28 (altered from Hirschfeld and Leveillé) is very confusing, and the anatomy of the brachial and lumbar plexuses is strange. A reader who should gather his notions of the functions of spinal ganglia from pp. 110-113 would have a very wrong idea of the state of our physiological knowledge; nor does the odd expression, "the immense discovery by Claude Bernard, of the so-called vaso-motor system of nerves," possess much justification as regards historical accuracy.[1]

The four last lectures contain—necessarily mingled with familiar elementary considerations—a statement of the results arrived at by Professors Gotch and Horsley from their electrical investigation of nerve-impulses in afferent and efferent nerve-channels, and to the expert form the most important part of the book. We begin, therefore, to read more closely, still bearing in mind, as indeed is suggested by the style, the requirements of non-expert readers. Nothing arrests attention on the first two pages. On p. 129 we pause at this sentence:—"It is very interesting to see that the protoplasm of a nerve conductor has a distinctly longitudinal arrangement, which, it is not going too far to suggest may, by virtue of this fact, be more adapted for the polarization of its molecules for the better transmission of nerve-impulses." Having dissected out the possible meaning of this sentence we proceed. Two pages further we are stopped for a moment by a confusion between the local excitability of nerve and its conductivity. On the next page (p. 132) we demur to the assertion that "secondary tetanus depends upon the electrotonic state of the first preparation." On page 138 we find no reason to accept the distinction that "no doubt may reasonably exist that active nerve yields products of oxidation, which doubt certainly exists as to the acidification of nerve." Both facts are possible but unproven; no proof whatever has been attempted of the first; the second has been investigated with positive and with negative results. Page 146 includes a figure in which the current is *not* shown as an action current, but the reverse; moreover, with the instrument figured (capillary electrometer), *no current* is under observation.

But these twenty pages are enough, and we shall have but little space to discuss what forms the main positive differentia between Prof. Horsley's book and other books of the same class, *i.e.*, the conclusions derived from electrical data.

The conditions of criticism in this connection are altogether different, and we need not stop to examine into the accuracy of elementary points. Prof. Horsley is now addressing himself to an expert audience; his reasoning and his data have yet to pass through the refining fires of doubt and of objection, with, it is to be hoped, ultimate confirmation. The principle of the method of investigation is a well-established one; we know that electrical variations are indicators of functional variations; in the spinal cord, as elsewhere, functional activity may therefore be roughly gauged by galvanometer or by electrometer. Gotch and Horsley did this as regards efferent channels and afferent channels; as regards the first they found by the electrometer that the character of discharge in the pyramidal tract does not differ from its character in motor nerves; as regards the afferent tract they find that impulses pass up the cord chiefly in the posterior column of the same side. These conclusions may be admitted without imprudence. But the conclusions that may not safely be admitted without further experimental elaboration, are those relating to the functional discharges (inferred from electrical discharges) up and down the anterior and posterior roots, and to the quantitative distribution of centripetal impulses in the various columns of the cord. As regards this second point the physical conditions are not sufficiently analyzed (either in this volume or in the original paper) for us to admit, *e.g.*, that average galvanometric swings of 60 and 20 indicate a passage of afferent impulses in the proportions 60 and 20 per cent. in the posterior and in the lateral columns respectively. That the deflection was proportional to the number of fibres excited, is an assumption requiring proof (p. 212, *cf.* also pp. 145, 159, 160).

As regards the first point, it was found that electrical discharges pass easily *down* as well as *up* the posterior

[1] In point of time Brown-Séquard is the true discoverer of vaso-motor nerves. Bernard's experiments were made subsequently, and interpreted otherwise.

"D'après ces expériences, il n'est donc pas possible d'expliquer le réchauffement des parties par une prétendue paralysie des artères, qui, à raison d'un élargissement passif, laisseraient circuler une plus grande quantité de sang.

"Si alors [*i.e.* en galvanisant] les artères, comme les veines, se resserrent et reviennent sur elles-mêmes, cela tient à ce qu'il n'y a plus de sang pour les distendre, mais ce n'est pas du tout l'effet d'un resserrement actif des vaisseaux.

"... il ne peut venir à l'idée de personne de penser à rapporter [le phénomène circulatoire qui succède à la section du nerf sympathique] à une paralysie pure et simple des artères." (Bernard, *Annales des Sciences Naturelles*, 1854, p. 198.)

root, but are "blocked" *up* the anterior root, and diminished *down* that root But in the inferences *qua* functional impulses derived from these data, two considerations appear to have been insufficiently borne in mind—(1) The rapid death of interrupting grey matter as compared with the endurance of white matter, and (2) the disproportionate magnitude of negative variations by *electrical* excitation as compared with negative variations by *functional* excitation The contrast between interrupted and non-interrupted tracts, as regards the transmission, gauged electrically, may have been in part due to the first cause, and an adequate recognition of the second fact would have withheld Prof Horsley from expressing astonishment "a revelation to us" is his phrase—at finding the electrical variation in a nerve eight or ten times as great by direct electrical excitation as by discharge of a nerve centre Du Bois-Reymond's analogous deflections obtained on strychninized frogs were 1° to 4° *versus* 40° by direct electrical excitation A functional discharge *down* posterior roots, if proved to occur, is a new and surprising phenomenon, but its existence is not *at present* proved by the existence of an electrical discharge, electrical effects by electrical excitation are tainted evidence, electrical effects down the posterior roots by functional excitations above, although incidentally touched upon, were not exhaustively examined, and considering the recognized dangers of experimental fallacy, we may not admit as proved that nervous impulses are discharged down afferent channels Prof Horsley infers unreservedly that functional discharge occurs *down* the posterior roots, and that centripetal impulses *up* the anterior roots are blocked at the cord This he regards as striking evidence of the truth of the kinæsthetic doctrine (*i e*, that nerve action starts from the afferent or sensory side of the nerve centre, p 170), but the connection between this presumed functional downflow in afferent channels and kinæsthesis is not made apparent, up-flow in afferent channels is matter of common knowledge; up flow by efferent channels has (so far as we know) been contended for by no one since Lewes But as regards these last points, they may be expected to receive fuller and more precise analysis in the promised volumes on the brain and on physiological psychology

ELECTROTECHNICAL TRAINING

Electrical Engineering as a Profession and How to Enter It. By A D Southam. (London Whittaker and Co, 1892)

THIS book consists of a collection of extracts from the notices of various firms regarding apprentices and articled pupils, and from the prospectuses of colleges which give an education in electrical engineering It reminds us of the gorgeous but depressing volumes one has met so often in one's summer outing, containing particulars of hotels in Aden, hotels in Algiers, hotels in Andermatt, &c, each hotel possessing, at least so it is said in the gilt-edged page advertisement, every possible attraction—a magnificent view, a first-rate cuisine, electric light, ascenseur, and all the other dreariness of a bandboxy barrack.

First we thought that the length of description which the author had given to a particular technical educational establishment was a measure of its goodness, but that idea we dismissed when we found that only three pages of description were given to that technical college in South Kensington, regarding which the author says "This institution deservedly stands at the head of all the technical institutions in this country" Next it occurred to us that the author might have acted on the "good wine needs no bush" principle, but that hypothesis had to follow the other, for we feel sure that the Walker Engineering Laboratory at Liverpool is not bad, and yet it requires fifteen pages of talking about Then we wondered whether each professor had been asked to write as much as he liked, so that the length of the description of a particular set of laboratories was in proportion to the leisure of the writer, and lastly, we have been speculating whether the likeness to the "Hotels of the World" book might not be quite complete, and the length of the description was a measure of the length of the purse of the advertiser

However, be the plan of the compilation what it may, the book contains a good deal of information, also some salutary advice with which we quite agree —"Undoubtedly the best training for a young man entering the electrical profession is to go through the course at one of the technical schools or colleges, and then when thoroughly grounded in the theory and having a general idea of the practice of his profession, to be articled for some months to a good firm of electrical engineers, where he will be able to acquaint himself with the practical part of his business as actually carried out on commercial principles," and again, "if he then goes to both a Technical College and is also articled, it is advisable that the former should precede the latter, for the reason that when he is placed in the workshop his previous technical training will enable him to appreciate and see the importance of much which he would otherwise have overlooked"

For the fathers who desire to place their sons directly in a works on leaving school, there is given a long list of engineering firms who are willing to receive £300 and the lad, some are willing to take only one hundred and twenty guineas a year, from year to year, or even as little as £100 a year—and the lad In many cases a month's trial is allowed, but judging from the ignorance of elementary mathematics and science displayed by many articled pupils in works, we presume that either these subjects are not required, or a month is not a long enough time for this astonishing ignorance to be discovered Naturally enough these firms do not bind themselves to provide work for these articled pupils when their term is finished, indeed we know of a firm with over 100 articled pupils which is applying elsewhere for an assistant

When will the parental idea die out that a lad who is pitchforked into a works must turn out an engineer? No doubt many of our successful engineers never received any education in a technical college; so many of our battles were won by men armed only with bows and arrows, but that is no reason for confining the equipment of a modern regiment to these primitive weapons. Either the teaching given at a technical college materially helps the lad in his subsequent practice in the works, or it is a fraud and ought to be stamped out If it affords real help

to the lad, then why, we ask, do not the firms insist on their pupils obtaining it before they enter the works?

Mere evening instruction for a lad who has been hammering, say, from 6 a m to 6 p m is well-nigh useless, and at the best ought to be regarded only as a makeshift for those who are compelled to spend the day earning their living To place a lad at a technical college for two years, and then for two years at a works would cost, as far as fees and premium are concerned, about £250 To article him for three years at the works about £300 When will parents see that the cheaper course is far the better, and when will firms refuse to take an articled pupil unless he has already acquired that theoretical knowledge which is necessary to enable him to benefit by a works training? The father who articles his son to an engineering firm immediately the lad leaves school and expects him to pick up his technical education at odd moments, may be more liberal in his money, but certainly is no more liberal in his ideas than the parents who sent their sons to receive their practical training at Dotheboy's Hall "Now, then, where's the first boy?" "Please, sir, he's cleaning the back parlour window" "So he is, to be sure," rejoined Squeers "We go upon the practical mode of teaching, Nickleby C-l-e-a-n, clean, verb active, to make bright, to scour W-i-n, win, d-e-r, der, winder, a casement When a boy knows this out of a book he goes and does it"

P D

HYGIENE AND PUBLIC HEALTH

A Treatise on Hygiene and Public Health Edited by T Stevenson, M D, F R C P (Official Analyst to the Home Office), and Shirley Murphy (Medical Officer of Health of the Administrative County of London) Vol I

THIS is a treatise consisting of various contributions from different writers In the selection of authors it has been wisely decided not to limit the choice to members of the medical profession, and the wisdom of this decision has been exemplified in the acquisition of two of the very best articles which the book contains, *i e* that by P Gordon Smith, F R I B A, and Keith D Young, F R I B A, entitled "The Dwelling," and that by W N Shaw, F R S, headed "Warming and Ventilation"

There are at present several excellent small works upon hygiene and public health, but these of necessity treat of the subject in far too cursory a manner—indeed, they are designed more to meet the repuirements of candidates for the Public Health Diplomas now granted by many examining Boards This work is evidently intended as a book of reference, and there is no doubt that it will be of great value to those from whom a special knowledge of public health work is demanded While, then, the last year or two have been remarkably fruitful in the production of works upon the subject here treated of, the volume before us will not be one jot the less appreciated on this account, for it meets a want which must long have been felt among those who desire a better and more inclusive knowledge of public health matters than was hitherto accessible in a collective form

It is needless to insist that the work is all well done, and that any shortcomings must, of necessity, be faults of omission rather than of commission, for the list of contributors includes those who occupy some of the foremost positions as authorities upon the subjects of which they treat It is not an easy task—and one is conscious of running great risk of appearing arrogant—to single out those sections especially deserving of praise If this is permissible in such a work, we should point to the two articles already mentioned as occupying a foremost place —indeed, the article upon "Warming and Ventilation" is a little too exhaustive and technical in its physical aspect, and deals too briefly and sparingly with the commoner provisions now used for both the purposes of warming and ventilation,—a shortcoming which has the effect of somewhat sacrificing the practical utility of the article to its bulk, when viewed from the health officer's standpoint It would not be easy to speak in terms too high of the all-round excellence of the article upon "Disposal of Refuse," by Prof W H Corfield, M A, M D, and Louis C Parkes, M D, D P H, and the work of compiling this section could not have been entrusted to more capable hands "Water," by T Stevenson, M D, is a capital article, but one would like to have seen in it more about the methods of collecting water and distributing it, and of the risks which the water runs of pollution in and around dwellings

In the preface we read that "it has been the desire of the editors that the several papers which these volumes contain should present a fair account of the knowledge, so far as obtainable, of the subjects of which they treat", and this is invariably achieved, for where the account is not an excellent one, it is always more than a "fair one

The contribution upon "Air," by Prof J Lane Notter, M A, M D, is too short, and does not nearly include all the material given in his edition of Edmund Parke's work, and the same fault may be found with the articles upon "Hospital Hygiene," by H G Howse, M S, and "The Inspection of Meat," by E W Hope, M D, D Sc

"Systematic Physical Education"—a subject which has been all too little studied in this country—is well and spiritedly treated of by F Treves, F R C S

The articles upon "Baths," by H Hale White, M D, "Clothing," by G V Poore, M D, "Food," by Sidney Martin, M D, "Soil," by S M Copeman, M A, M D, D P H, "Meteorology," by G J Symons, F R S, "The Influence of Climate upon Health," by C T Williams, M A, M D, "Offensive and Noxious Businesses," by T W Hime, B A, M D, and "Slaughter Houses and their Administration," by E W Hope, M D, D Sc, are all good, though some of them might have been fuller The article upon "The Influence of Climate upon Health" might with advantage have considered much more fully the reasons why the various climatic conditions influence the health of man in the way they do The contribution upon "Meteorology," which is capitally illustrated, and one of the most useful in the book, might also have considered the physical causes which affect the readings of the various instruments, and dealt more fully with the principles upon which these are constructed. The article upon "Food" is excellent in some respects, but an attempt to convey to the reader, in an abstract form, the methods of food analysis fails—as

it always does when such a subject is treated of in brief space—to be of great assistance to the reader

The index is good, and the book is a valuable addition to Public Health literature.

OUR BOOK SHELF

Lehrbuch der Botanik nach dem gegenwärtigen Stand der Wissenschaft Bearbeitet von Dr A B Frank Erster Band Zellenlehre, Anatomie und Physiologie 8vo 670 Seiten, mit 227 Abbildungen in Holzschnitt (Leipzig Wilhelm Engelmann, 1892)

THIS is essentially a fifth edition of Sachs's renowned "Lehrbuch der Botanik," the fourth and last German edition of which appeared as long ago as 1874 An English edition, emended and augmented by the translator, Dr S H Vines, was published in 1882 Now, ten years later, Dr Frank has written a completely new work As the author tells us in his preface, he was requested in 1890 to prepare a new edition of Sachs's book, but he has adopted the wiser course of making himself responsible for the whole Nevertheless, free use has been made of Sachs's excellent illustrations, upwards of ninety out of the two hundred and twenty-seven having been taken from that source, "because the author could not replace them by better ones" About sixty are borrowed from other authors, and about seventy of them are original, or at least Dr Frank's own, for some of them have appeared elsewhere A number of them are reduced from Frank and Tschirch's "Wandtafeln" Certainly the book is admirably illustrated In the limitation and arrangement of the material the author has followed Sachs in a general way, though he has separated the physiology and anatomy from morphology and classification The two latter branches are to be dealt with in a second volume, promised early next year So far as the present volume is concerned, we can strongly recommend it to the student familiar with the German language It is written in a clear, succinct style, and, so far as we have been able to test it, it is well up to date Dr Frank is well known as a writer and teacher of botany, and especially for his researches and experiments relating to the nutrition of plants The sources of the nitrogen of plants and symbiosis are two subjects to which the author has devoted much attention, and they are discussed in some detail from his own standpoint We are glad to see that copious and complete references are given to the books and articles of the principal writers on the various subjects, whose views are discussed or adopted Unfortunately there is no index, and it is not easy to find one's way through the table of contents True, a "carefully prepared" index is promised with the second volume, but a separate one to each volume would be far more convenient and time-saving It is not as though the second volume was a continuation of the first, and it is to be hoped that the author and publisher will even yet see their way to provide this facility for using the work

Arithmetical Chemistry Part II Book B By C J Woodward, B Sc (London Simpkin, Marshall, Hamilton, Kent, and Co Birmingham Cornish Bros, 1892)

THE student will find in the present edition of this work what is practically a new book, as the author has enlarged and entirely rewritten the original publication The opening lessons treat of analyses, the formulæ of minerals, Dalton's law of partial pressures, gas analysis, &c, and are on the whole satisfactory The introductory portions of the lessons, which embody the principles involved in the exercises, and contain typical examples fully worked out, are clear, as a rule, and the exercises themselves are both suggestive and useful. The same may be said of the concluding part of the book, wherein are briefly discussed atomic weight determinations, and the various means of controlling atomic weights, calorific power and intensity, heats of formation, dissociation, and gaseous phenomena, comprising the kinetic theory, diffusion, and absorption by water

The intermediate lessons on molecular weights are, however, not up to the standard of the others It is not made plain when discussing Avogadro's law that a vapour density observation, when possible, is the decisive mode of fixing the molecular weight of a compound The vague description of the apparatus used in measuring osmotic pressure can only confuse the reader, and loose statements such as "*solutions* behave as gases," p 51, must have the same effect The relationships established in connection with the vapour pressures of solutions only hold if the dissolved substance is practically non-volatile, this point is omitted, and the definition given of equimolecular solutions is not the one in common use. Indeed, the entire treatment of the properties of solutions as applied to molecular weight observations, although it may perhaps enable the student to solve problems, is much too fragmentary and loosely put together to give him an adequate idea of what is known on the subject It may also be pointed out as somewhat late in the day to give a few of Kopp's conclusions as an account of specific volume

Among minor corrections it may be noted that on p 6, in the first erratum, solvent should be solution, vapour-tension might often be replaced by vapour-pressure, xylol should be xylene, and amyl benzoat should be amyl benzoate, on p 48 "Ostwald's Solutions" might be included in the list of English works to which the student is referred

The book contains an index, a list of answers, and a collection of the questions in arithmetical chemistry set at the Honours examinations of the Science and Art Department, and at the B Sc examinations of London University A portion of the author's A B C Five figure logarithms is presented with this edition J W R

Lessons in Heat and Light By D E Jones, B Sc (London Macmillan and Co, 1892)

THE success of a previous work on "Heat, Light, and Sound," has led Prof Jones to extend the two former parts, and publish them separately for the use of schools and junior classes in colleges As an introduction to the study of experimental physics, the book cannot fail to be of great value The principles of the subjects are very clearly stated, and the experiments from which they have been deduced are fully described Most of the experiments may be easily performed by students, the instructions being sufficiently clear to guarantee success Numerous arithmetical examples, partly selected from the author's "Examples in Physics," are added at the ends of the various chapters The physiographic bearings of the subject of heat have been brought well to the front, thus the origin of the Gulf Stream, trade winds, and the formation of rain and snow are explained. Many of the diagrams have been carefully drawn to scale, in order to give the student an idea of the dimensions of the apparatus which may be conveniently employed in performing the experiments

Elements of Magnetism and Electricity By John Angell, F C S, F I C (London. Collins, Sons, and Co., 1892.)

THIS is a new edition of one of the best known text-books for use in connection with the classes under the control of the Science and Art Department The book calls for no special remark, but the fact that a hundred thousand copies have already been disposed of seems to demonstrate its usefulness Experiments and illustrations are its special features

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Further Notes on a recent Volcanic Island in the Pacific

THE volcanic island—Falcon Island—in the Tonga group in the Pacific, of the recent appearance of which an account is given in NATURE, Vol. xli., p. 276, has recently been passed by a French vessel of war, the *Duchaffault*, which reports that the island is not now more than 25 feet high.

In October, 1889, when examined by Commander Oldham, it was 153 feet high, and a little over a mile long. Nearly entirely composed of ashes, it was rapidly washing away, and by the account above, it would seem that more than one half the island must now have disappeared. W. J. L. WHARTON.

October 20.

Earth-fractures and Mars "Canals."

ON seeing the figure of the so-called "canals" of Mars, published in NATURE of a few weeks back, I was at once reminded of the pattern assumed by the cracks of glass broken by torsion, as in Daubrée's well-known geological experiment.

I enclose a photograph of part of a large slab of glass broken in this way in a class experiment of my own, and although other slabs, which have unfortunately not been preserved, exhibited, if I remember rightly, still more Martial-looking networks, I think that the general resemblance is obvious enough in this case.

It may perhaps be well to explain to non-geological readers of NATURE that Daubrée's glass-breaking[1] is regarded by many as reproducing in miniature the kind of fractures which are found to occur in those portions of the earth's crust with which we are acquainted, and that by torsion only has it proved possible to imitate the peculiar pattern assumed by such fractures, whether

they be joints or dislocations. It is further held by many that such lines of fracture in such patterns are a necessary result of the shrinking of the outer coat of a planet in course of cooling.

Mere fractures, such as we meet with in our own planet, could, of course, not be seen from any considerable distance, and if the circumstances of denudation were the same in Mars as with us, the "canals" could certainly not be the representatives of our usually hidden and featureless earth-cracks. There seems, however, to exist, in the extraordinarily rapid melting of gigantic ice-fields described by Prof. Norman Lockyer, some evidence of denuding power in Mars on a scale enormously larger than is the case with us. Earth-fractures—and for the matter of that Mars fractures too—must many of them be lines of weakness along which denudation acts more freely than elsewhere, and if this denudation be phenomenal and cataclysmic, as appears to be likely in Mars, wide valleys or channels capable of being distinguished at great distances would soon be scoured out along them.

I would wish especially to draw attention to the three following points observable in the photograph, viz., the two marked directions in which the crack lines run, one set crossing the others often at, or very nearly at, right angles; their occasional doubling and rough parallelism for some distance; and their frequent sudden stoppage—three of the features most noticeable in the Mars lines. G. A. LEBOUR.

Durham Coll. Science, Newcastle, October 13.

[1] Not "ice-breaking" as a mistranslation of the word "glace" has caused it to be described in some English text-books.

A Wave of Wasp-Life.

MR. HUDSON'S charming work on "The Naturalist in La Plata" reminds me of a very interesting wave of wasp life which appeared in Wisconsin in the summer of 1886. We were living at the time in our summer house at Pine Lake, and were making observations on the habits of the different animals in the neighbourhood.

In the latter part of July we suddenly found ourselves surrounded by large numbers of yellow jackets and hornets. Everywhere through the woods and fields a veritable plague of wasps seemed to have descended upon the earth. During all the month of August we heard the same report from summer residents within a radius of twelve or fifteen miles of Pine Lake. In our immediate neighbourhood we knew of forty-seven nests. Allowing 1500 wasps to a nest—a very low estimate for that season of the year—this gave us over 70,000 wasps. Plates of meat and bones that were set outside for the cats were immediately covered with them, and in spite of screens in doors and windows they even entered the house, alighting on the food at the dinner-table, or darting about and catching flies.

The cause of this sudden increase in the number of wasps was evidently a general one, since it acted in the same way upon three species—*Vespa vidua*, *V. maculata* and *V. germanica*. An examination of the Signal Service statistics does not show anything unusual in the preceding winter and spring, but either the weather must have been especially favourable, lessening the ordinary death-rate of the queens, or there must have been a marked decrease in the parasites or other enemies which ordinarily keep these species in check.

The duration of the favourable conditions proved brief enough. It is probable that every one of our forty-seven nests furnished, at the very lowest estimate, one hundred developed and fertilized queens to start forty-seven hundred new nests in the following year; yet the increase in the checks to the too great ascendency of these species more than counter-balanced the abnormal increase. The winter of 1886-87 was not especially severe, but in the following summer the most careful search on our part, and on the part of others, whose efforts were stimulated by the offer of rewards, only gave us four nests in our neighbourhood, and on all sides we were met by the inquiry: "What has become of the wasps?" G. W. PECKHAM.

Milwaukee, Wisconsin, October 12.

Note on the Occurrence of a Freshwater Nemertine in England.

A FEW days after reading M. de Guerne's "History of Freshwater Nemerteans," published in the August number of the *Annals*, I happened upon a specimen of the group amongst the roots of some water plants, which I collected in the river Cherwell, close to Oxford. I was, at the time, searching for the cocoons of a new Rhinodrilid worm, of which a description will shortly appear. The gathered roots, with the cocoons, were placed in a bottle of water, in order that the worms might hatch out. On examining the bottle two days later, namely, on September 5, I noticed a small bright orange animal, about half an inch long when extended, creeping amongst the cocoons. Further observation with the microscope showed that it was a species of *Tetrastemma*. Unfortunately the animal was crushed before I had done more than sketch the general appearance and make some few observations, and I have not yet succeeded in finding more specimens; so that I am unable to state how far it agrees with or differs from the previously known freshwater forms enumerated by M. de Guerne, most of which are included by Silliman and later authors under the title *Tetrastemma aquarum dulcium*.

In one or two points, however, my sketches show certain differences from those of Silliman:—

(*a*) The colour (orange) is due to pigment in the skin, and not to the red colour of the nervous system. I may mention that Dugès' species, "*Prostoma clepsinoides*," was yellow ochre, and "*Pr. lumbricoideum*" was yellow marbled with red; whilst Leidy's "*Emea rubra*" was yellowish flesh-coloured (probably due to the hæmoglobin in the nervous system).

(*b*) The anterior pair of eye-spots is further from the prostomium than in Silliman's drawing. I found no third pair of eye spots, which, however, it is stated, is absent in the young.

(*c*) The ciliated pits are further forward, being midway between the brain and the anterior end of the body.

(*d*) The proboscis and its retractor muscle are much more undulating, when withdrawn into the body, than Silliman shows.

The proboscidial spine, with its groups of accessory spines, agrees very closely with the figures given by Silliman.

I can say nothing about the generative organs. For the present, then, I must leave undecided the specific name of this British *Tetrastemma*. W. BLAXLAND BENHAM.

Anatomical Department, Museum, Oxford, Oct. 12.

Protective Mimicry

MR. BATESON'S letter on "Aggressive Mimicry" (NATURE, October 20) recalls to my mind a curious case of protective mimicry which came under my notice last August on Dartmoor. Large patches of the heath had been burnt, a common practice on the moorlands to ensure a fresh young growth for the sheep. The whole ground was alive with a common species of orthoptera (Locustina), the small green grasshopper with short antennæ. They leapt aside at every step in the short grass and scrubby heath; upon the burnt patches they were equally numerous, but with this difference—all, without exception, were coal black on abdomen, thorax, and head, whilst the wings were of an ashen hue. So much did the colour adaptation resemble the blackened turf and heath they hopped amongst it was almost impossible to follow them with the eye; we made many amusing attempts, but were nearly always defeated. I measured one of these burnt patches, and found it to be from thirty to forty yards square. A yard or two from this, on the untouched herbage all the Locustina were bright green. I found one specimen on the borderland in a transition state, not dull all over as I had expected, but in spots and patches of bright green and black. One enemy at least of these insects abounded on the moor, namely, the common lizard (*Zootoca vivipara*), for I have observed there is no food lizards will eat more greedily than grasshoppers. I have seen some that I have in captivity swallow twenty or thirty in two or three minutes, even after their usual meal of worms. They always became greatly excited, if one may apply so warm an expression to such cold blooded animals, and rushed about the case when a collection of live grasshoppers were thrown to them. Certainly I was much struck by the rapid action of the power possessed by these Locustina on Dartmoor of assimilation to environment, and did not doubt but that this colour adaptation was for the purpose of protection, the eye producing by reflex action the change in the pigment cells. ROSE HAIG THOMAS.

STELLAR PARALLAX[1]

THE Delegates of the University Press have recently published the results of Prof. Pritchard's systematic investigations into the parallax of those stars of the second magnitude whose North declination permits the inquiry to be made with facility and advantage in these latitudes. Our first feeling on glancing over the contents of this *brochure* must be one of hearty congratulation to the distinguished professor that he has been permitted to see the full outcome of a protracted inquiry, conducted at a period in his life when a less energetic astronomer would have felt himself justified in withdrawing from active participation in scientific research.

[1] "Researches in Stellar Parallax by the aid of Photography." By Charles Pritchard, D.D., F.R.S., Savilian Professor of Astronomy in Oxford.

Prof. Pritchard might well have been content to rest on the laurels he had won, and to have staked his reputation upon that career of acknowledged utility which has marked his direction of the Oxford University Observatory.

Immediately on the completion of the photometrical examination of Argelander's Uranometria, and with a zeal that admitted of no delay, Professor Pritchard busied himself with this inquiry into the parallax of stars of the second magnitude. But if the inquiry was undertaken with eagerness, and pursued with ardour and resolution, it was not characterized by hurry, or its success imperilled by incompleteness. Confident himself that photographic methods possessed the requisite accuracy to make the research successful and trustworthy, the Savilian Professor set to work to establish the reliable character of measurements made on sensitized films, and not till that confidence was demonstrated did he embark upon the larger work now under notice. These preliminary inquiries have been published in a series of papers in the proceedings of the Royal and Royal Astronomical Societies, and the confidence gradually acquired by enlarged experience induced him to proceed with the determination of the parallax of 61 Cygni, the results of which are published in detail in the third fasciculus of the Annals of the University Observatory. In this case he selected four stars in the immediate neighbourhood of the principal star, and sought the difference of parallax between each of the components and of the four stars of comparison. This long research may be regarded by some as a work of supererogation, inasmuch as the labours of Bessel and that of many later astronomers have satisfactorily settled the parallax of this star within very approximate limits. But if we properly understand the motives of Prof. Pritchard, his intention was not so much to seek anew the parallax of that system, as to discover with what degree of accuracy the method of photography, hitherto unapplied in this direction, represented the work of others made directly in the field of the telescope. Nor was this his only view. By selecting four stars in the immediate neighbourhood of 61 Cygni and seeking the difference of parallax between these stars of comparison and each of the components of the system, he instituted a very severe inquiry as to the trustworthiness of that method, which he had imagined as capable of dealing with the delicate question of stellar parallax. The severity of the test consists in deducing the same value of the parallax (eight in all) from each set of measures, and as a matter of fact the accordance, *inter se* between these several determinations is as close as could have been anticipated, and likewise in satisfactory unison with the work of other astronomers.

The completeness of this inquiry and the publication of it in detail have had two happy results. In the first place, Prof. Pritchard has, in the present instance, been able to confine the printing within very narrow limits, so narrow, indeed, as possibly not to have done himself justice. The details of his process, the mutual agreement of his measures, and his method of discussion having all been fully set out in his previous work, he has not felt himself obliged to enter into these minute particulars, but has contented himself with presenting the results. This method of arrangement, no doubt suggested in the first place by economical motives, has afforded opportunity for adding a very interesting history of the processes and results that have hitherto been followed with more or less success by others, and also the exhibition in a concise form of the different values of the more trustworthy determinations, derived by previous observers. The second advantage, immediately arising from the earlier investigations, is, that an examination of those results has shown that no increase of accuracy (commensurate with the increased labour at

least) was obtained by continuing the observations of the stars throughout the whole of the year, that is, to secure observations in all positions of the parallactic ellipse. If the measures were confined to those epochs when the parallactic displacements were greatest, and a sufficient number of observations secured at those critical times, a determination of parallax could be relied upon to within about one thirtieth of a second of arc. This is approximately the limit of accuracy that Professor Pritchard hoped to reach, and in this selection he appears to have been guided by the conviction, that in the present condition of cosmical inquiries, to which stellar parallax bears the closest relation, it is of more importance to know within very narrow limits the parallaxes of many stars than seek with the utmost accuracy the parallax of a very few. And in this respect there can be no doubt but that Prof. Pritchard's judgment is correct. The former is the view of a philosopher, the latter that of a conscientious and painstaking observer. Guided by the broader view, the result of his work has been to enrich the data at the command of students of cosmical science by assigning the approximate distance to some thirty stars, a number which bears no inconsiderable proportion to the total number of separate determinations made by all other astronomers combined.

Prof. Pritchard's view of the history of stellar parallax is that of a scientific struggle, a continual and severe wrestle on the part of the astronomer with the inevitable inaccuracy of observation and imperfect instruments, in which sometimes one opponent, sometimes the other, has the mastery. He passes in his historic survey rapidly over those days when from various obvious causes the detection of stellar parallax was scarcely possible, moved however to admiration by, and induced to linger over, the success that attended the early observations of Molyneux in the case of γ Draconis when discussed, a century later, by Auwers, a success that later observers have struggled to repeat ineffectually. He brings before us, but touches with a light and kindly hand, the dispute that embittered the lives of Brinkley and of Pond, but it is not difficult in reading a little between the lines to see with whom his sympathies rest. Later on in the history of the research, Henderson meets with his deserts, as a clear-sighted astronomer of distinguished ability, cautious and persevering, and one who in the struggle after accuracy obtained an undoubted measure of success. This historical introduction will we think be read with pleasure by many who may have no particular interest in this special subject of inquiry. The comments of one who has encountered and overcome many similar difficulties, and has kindly sympathy with all who have travelled along the same path, cannot but be of interest and of value, and we could have wished that this portion of the book had been considerably extended. How many astronomers are now acquainted, with any degree of adequacy, with the serious difficulties that attended the early application of the heliometer in this department of research, and with the dispute that raged long and dubiously around the names of Wichmann and of Schluter? All are willing to admit that in the hands of many competent observers—it would be invidious to mention any without naming all—the heliometer is doing splendid work, but the difficulties with which the early masters had to cope are now all but forgotten, and it is certainly wise to treasure a sympathetic remembrance for the earlier exponents of the improved and successful methods now in vogue.

The last portion of Prof. Pritchard's history is occupied with the bearing of stellar parallax on the problem of the construction of the stellar universe. He seems to have had before his mind two questions, which, long hovering in an unexpressed form, were first formally enunciated by Dr. Gill. The first question is, What are the average parallaxes of stars of the first, second, third, and fourth magnitude respectively compared with those of fainter magnitude? To this question the Savilian Professor replies very cautiously. The researches of Dr. Elkin on stars of the first magnitude point to an average parallax of 0″·089 for stars of that class, and just as certainly Prof. Pritchard's researches point to an average parallax of 0″·056 for stars of the second magnitude. But he pertinently asks what can be understood by an average of distances (as indicated by parallaxes) in cases where the separate elements vary from actual zero to half a second, and where moreover many of the brighter members are the furthest removed from us? Notwithstanding these exceptional cases, which challenge attention, the fact remains and it is apparently the only conclusion which can be drawn with any certainty, that the stars of the first magnitude are on the whole nearer to us than those of the second, and that these again are as a whole nearer to us than the faint stars with which they have been compared. With conclusions of this sort it would seem that astronomers will have to content themselves for some time to come.

The second question which Dr. Gill suggested or formulated was—What connection does there exist between the parallax of a star and the amount and direction of its proper motion?—or can it be proved that there is no such connection or relation? The answer given to this second query is even less satisfactory than to the former. Prof. Pritchard contents himself by exhibiting in a tabular form the parallax and the proper motion of all stars that have been successfully handled, and the only conclusion drawn or warranted, is a suggestion that there is at least quite as close a connection between the apparent proper motion of a star and its distance from us, as there is between its distance and its magnitude.

If we examine or attempt to trace any connection between the mass, the brilliancy and the distance of a star, we are baffled by the same kind of uncertainty, arising in some measure from the paucity of instances in which it is possible to make the inquiry, and we are reluctantly forced to admit that such investigations are premature. At least that would be the conclusion of an ordinary mind, but here it is that Prof. Pritchard sees his opportunity for future efforts and renewed vigour. With an energy that must be the admiration of his friends, he selects for further investigation two subjects, either of which might fully occupy the time and the hands of a younger man. He proposes in the first place to determine the parallaxes of several stars of the Pleiades, a few of the brighter as well as a few of the fainter, with the view of discovering whether the faint and the bright are indiscriminately mixed at that distance. The second subject of his proposed inquiry is not less interesting. It consists in the investigation of the distances of some of the binary systems from our sun, and from a more complete knowledge of the masses, the mutual distances, and the parallaxes of these systems, Prof. Pritchard thinks it not unlikely that many interesting and possibly unexpected associations may reasonably be anticipated, thereby affording us some further insight into the constitution and the mechanism of the Stellar Universe. We can only hope that Prof. Pritchard's health and strength may be spared to witness the completion of this programme, but in that case we are assured he would immediately sketch out for himself some new field of inquiry, and court even longer and more protracted labour.

CONTRIBUTIONS TO THE STUDY OF DISINFECTION[1]

PROFESSOR J. MASCHEK, whose name is already familiar to us through his investigations on water bacteria, has brought together in pamphlet-form a large

[1] "Beiträge zur Theorie und Praxis der Desinfection, von Prof. J. Maschek." Im Selbstverlage des Verfassers, Leitmeritz.

number of experiments on the relative value of various disinfectants and disinfectant processes Since the introduction of Koch's methods, the study of the subject of disinfection has been immensely assisted, and it is now possible to take a more accurate measure of the extent to which micro-organisms are affected by different treatment, whether chemical or mechanical The stimulus which it has thus received has not unnaturally drawn a large number of workers into this particular field of inquiry, and the literature is already very unwieldy

One of the principal difficulties which surround the study of micro organisms is their individuality, their apparent idiosyncrasies, and this is not confined to closely allied varieties, but is found amongst members of one and the same species Thus, the previous history of a micro-organism, the nature of the culture material used, the temperature at which the cultivation has been kept, the age of the growth, &c, are all points which have to be taken into consideration as likely to influence the behaviour of the particular specimen under observation This sensitiveness of bacteria may possibly to some extent account for the discrepant results which have been obtained by different investigators, although working in similar directions, which has rendered the accurate appreciation of the value of these results a by no means easy task Again, what succeeds in a laboratory is not necessarily equally successful when carried out on a large scale, and it is this difficulty which has so frequently led to such disappointing results in actual practice

Prof Maschek has endeavoured by a series of most arduous and painstaking experiments to throw a little more light on some of the problems of disinfection, and in gathering up his work has wisely abstained from attempting an exhaustive survey of the general literature, restricting himself to a brief introduction and particular reference to those investigations with which he has been more closely concerned In the majority of the experiments the author employed Koch's well-known method of sterilized silk threads, each of which was subsequently impregnated with pure cultivations of a number of different pathogenic micro-organisms These were distributed in various parts of a room about 19-ft long, 13-ft wide, and 15½-ft high, on the ceiling, walls, corners, floor, &c, whilst in some cases they were wrapped up in different materials, such as filter-paper, muslin, linen, in order to imitate as nearly as possible the actual conditions under which the organisms might be supposed to be present in an infected room In each case, after the application of the disinfectants under observation, these silk threads were submitted to plate-cultivation, and in some instances their pathogenic properties were also tested by inoculation into animals

The first elaborate series of experiments was made with the vapour of corrosive sublimate, which some authorities have recommended as an effective germicidal agent, but quite apart from the difficulty of getting rid of the poisonous crystals of corrosive sublimate which remained attached to various parts of the room, Prof Maschek was not able to obtain satisfactory results, although every precaution was taken to ensure success In this respect his experiments differ from those of Konig, who confidently recommended its use for disinfection purposes The effect of chlorine gas was next tested and applied both in the dry and damp state The results were, however, far from encouraging, for even when employed in the damp state the spores were not destroyed In connection with these experiments a very instructive instance is given of the signal failure which accompanied the use of chlorine in the Alexander Hospital in St Petersburg, which was designed for receiving different infectious illnesses. Suspicion as to its efficacy was first aroused after its use in the disinfection of a ward in which diphtheria patients had been treated This ward was afterwards used for scarlet fever cases, and subsequently complications with diphtheria made their appearance, in consequence of which the ward was closed and disinfected with chlorine (A ward of 900 cubic metres capacity being subjected to the chlorine gas evolved in treating 50 kilos of chloride of lime with 65 kilos of hydrochloric acid) After the disinfection was completed, the ward was thoroughly cleansed and ventilated, and allowed to remain empty for seven months On its being re-opened for the reception of measles cases complications with diphtheria again arose, although the patients when taken into the ward were wholly free from diphtheria The measles patients were therefore removed, and the ward was again disinfected with chlorine, only this time a much larger quantity was employed (135 kilos of chloride of lime with 148 5 kilos of hydrochloric acid) after which it stood empty for another seven months Later on cases of smallpox were received into this ward, but diphtheria again appeared, the physician, two nurses, and an attendant being amongst those attacked, whilst complications with diphtheria again occurred amongst the patients In consequence of this the unfortunate ward was once more closed and thoroughly disinfected with chlorine, and was reopened for typhoid fever patients, but all children's cases were rigorously excluded, in consequence of their particular susceptibility to diphtheria After the adoption of this special precaution no further attacks of diphtheria were met with It might, however, be urged that as regards the infection of patients suffering from measles with diphtheria, the disease was possibly introduced from outside, and did not necessarily arise in the ward itself, were it not for the fact that there were three other wards in the hospital in which cases of measles were being treated at the same time, and no single attack of diphtheria occurred Krupin, who is the authority for these facts, confirming the valuelessness of chlorine for disinfecting purposes, found that the spores of anthrax were not destroyed in a hospital ward after being exposed to the action of this gas for more than 40 hours

A large number of experiments were made with a view to determining the number of micro-organisms present on the walls of a room For this purpose a small sterilized bit of sponge cut in the shape of a cube (of about half-inch side) was used to rub down a measured portion (about 4 square inches) of the wall The sponge was afterwards placed in a tube containing sterile melted gelatine and rotated gently, so as to disengage all the organisms on its surface The gelatine was then allowed to congeal on the sides of the tube, and after suitable incubation the colonies made their appearance, and were estimated in due course It was found that the numbers present on the walls and ceiling respectively varied considerably Near the floor the number was much greater than on the middle of the wall, whilst here again they were more abundant than on the ceiling For example, on one of the walls, at a distance of rather more than an inch from the ground, as many as 2,871 microbes were found, whilst on the ceiling over a similar area only 85 were discovered It was also noticed that those portions of the wall or ceiling which were exposed to currents of air from either the window or door exhibited generally a smaller number of bacteria than did places which were shielded from such draughts Prof Maschek further found that one rubbing was wholly insufficient to remove all the organisms from a given surface, and it was only after the process had been repeated five times that all bacterial life could be banished with certainty Although the figures thus obtained are of interest by way of comparison, yet it is difficult to believe that they represent the *actual* numbers present. The accuracy of this method, originally devised by Esmarch, rests on the assumption that on placing the sponge in the tube of melted gelatine and rotating it gently (for if this were done

violently the gelatine would froth, and the surface become covered with small bubbles, which would greatly interfere later with the counting of the colonies) all the organisms attached to the surface of the sponge would be removed. Now the sponge being left in the tube must necessarily obscure part of the gelatine surface; moreover, the interstices becoming soaked with gelatine, colonies would certainly develop within the sponge itself and escape detection, whilst it is quite inconceivable that gentle rotation would suffice to detach even all those organisms which are adherent even to the surface of the sponge.

Wall surfaces deprived of micro-organisms in the manner described above were subsequently sprayed with distilled water infected with different pathogenic bacteria, and after sufficient time had elapsed for these surfaces to dry, the effect of various disinfectants was tried. Numerous investigations are also recorded of the use of creolin, carbolic acid, and mixtures of the latter with solutions of corrosive sublimate. The effect of exposure to high temperatures, in apparatus specially constructed for the purpose, has also been tried, whilst the disinfection of sewage matters with lime is also carefully considered, and a large number of experiments recorded with the typhoid and cholera organisms.

The following interesting account is given as an illustration of the success which can be achieved in disinfection on a large scale. An epidemic of diphtheria broke out in a small village in Germany and proved particularly fatal amongst the children, indeed so alarming was its progress, that the Burgomaster was led to suggest the disinfection of the whole village. A public meeting was held and the inhabitants were instructed as to the nature of the epidemic, and the possibility of checking it by the combined action of every household. Public funds were devoted to the purchase and distribution of the requisite disinfectants, and during three days the whole place is described as smelling of carbolic, whilst in all directions windows and doors were to be seen wide open, a very unusual sight in the country, and more especially in the month of February when this occurred. The work of disinfection was carried on most systematically, every article which could not be either washed or baked was treated with a 5 per cent. solution of carbolic acid. In short, no efforts were spared to thoroughly disinfect everything, and the result was that although the epidemic before the commencement of this disinfecting crusade was steadily gaining ground, it suddenly stopped. This must be considered as a tribute to the sagacity and energy of the inhabitants; for, as Prof. Maschek points out, experience teaches us to expect a gradual decline, due to the possible weakening of the virus, so that towards the end of an epidemic the number of bad cases is lessened and recoveries are more frequent.

In conclusion the words of M. Duclaux may be appropriately quoted: "Les études sur les antiseptiques n'ont gagné que de s'encombrer de résultats qui se contredisent les uns les autres, et entre lesquels on ne peut faire un choix, précisément parcequ'ils ont été souvent obtenus en dehors des conditions d'une étude précise. Il faut donc abandonner cette méthode, scruter avec de plus en plus de soin la phénomène, faire de la science, en un mot." This "*faire de la science*" is precisely the spirit in which Prof. Maschek has carried out his experiments; the immense care with which they have been conducted, the ungrudging labour bestowed upon them should render his results a most valuable contribution to the subject of disinfection. It is only to be regretted that they are not published in a form in which they would be more likely to become known and appreciated.

GRACE C. FRANKLAND.

AN ETHNOGRAPHICAL SURVEY OF THE UNITED KINGDOM.

A CIRCULAR letter, which we have been asked to print, has just been issued on behalf of the Committee appointed by the British Association to organize an ethnographical survey of the United Kingdom. The Committee consists of Francis Galton, F.R.S., J. G. Garson, M.D. and E. W. Brabrook, F.S.A., representing the Anthropological Institute; Edward Clodd, G. L. Gomme, F.S.A., and Joseph Jacobs, M.A. representing the Folk-lore Society; H. S. Milman Director S.A., George Payne, F.S.A., and General Pitt Rivers, F.R.S., representing the Society of Antiquaries of London; Joseph Anderson, LL.D., Secretary of the Society of Antiquaries of Scotland; and A. C. Haddon, M.A., Professor of Zoology at the Royal College of Science of Dublin. The following is the circular letter:—

SIR,—The above-named Committee, in pursuance of the object for which they have been delegated by the Society of Antiquaries of London, the Folk-lore Society, and the Anthropological Institute, and appointed by the British Association, propose to record for certain typical villages and the neighbouring districts—

(1) Physical Types of the Inhabitants.
(2) Current Traditions and Beliefs.
(3) Peculiarities of Dialect.
(4) Monuments and other Remains of Ancient Culture; and
(5) Historical Evidence as to Continuity of Race.

As a first step, the Committee desire to form a list of such villages in the United Kingdom as appear especially to deserve ethnographic study, out of which a selection might afterwards be made for the Survey. The villages suitable for entry on the list are such as contain not less than a hundred adults, the large majority of whose forefathers have lived there so far back as can be traced, and of whom the desired physical measurements, with photographs, might be obtained.

It is believed by the Committee that such villages may exist in the districts with which you are acquainted, and, as you are eminently capable of affording help in this preliminary search, we have to request that you will do so by kindly furnishing the names of any that may occur to you, with a brief account of their several characteristics; mentioning at the same time the addresses of such of their residents as would be likely to support the Committee in pursuing their inquiry.

They would also be glad to be favoured with the names of any persons known to you in other districts to whom this circular letter might with propriety be addressed.

We are, Sir,
Yours faithfully,
FRANCIS GALTON, *Chairman*.
E. W. BRABROOK, *Secretary*.

All communications should be addressed to "The Secretary of the Ethnographic Survey, British Association, Burlington House, London, W."

NOTES.

THE Board of Trinity College, Dublin, on October 22 elected Dr. Arthur A. Rambaut, M.A., Royal Astronomer of Ireland, on the foundation of Dr. Francis Andrews. The election was made under the provisions of Letter Patent 32 George III., dated in 1792. The new Professor of Astronomy in the University of Dublin, graduated in 1881 as a Senior Moderator and Gold Medallist in Mathematics, since which period he has acted until now as Assistant at the Observatory at Dunsink

He is the author of several astronomical papers published in the Transactions of the Royal Irish Academy and of the Royal Dublin Society

IT is proposed that a portrait medal of M Hermite, the eminent mathematician, shall be struck in commemoration of his approaching seventieth birthday The circular asking for subscriptions is signed by a number of well known mathematicians

THE following nominations have been made for the Council of the London Mathematical Society for the session 1892-3. The ballot will be taken on November 10 For President, A B Kempe, F R S, Vice Presidents, A B Basset, F R S, E B Elliott, F R S, Prof Greenhill, F R S, Treasurer, Dr J Larmor, Hon Secs, Messrs M Jenkins and R Tucker, other members, Mr H F Baker, Dr Forsyth, F R S, Dr Glaisher, F R S, Mr J Hammond, Prof M J M Hill, Dr Hobson, Mr A E H Love, Major Macmahon, F R S, and Mr J J Walker, F R S After the election of the Council Prof Greenhill will read his Presidential Address

IN consequence of the alterations in the rooms of the Chemical Society, the first ordinary meeting of the Society will be held on Thursday, November 17, at 8 p m

THE late Dr C A Dohrn left his magnificent entomological collections, with the library connected with them, in trust to his son, Dr H Dohrn, who was directed to use them as the nucleus for the formation of a natural history museum in Stettin Dr H Dohrn has now not only carried out his father's wishes, but has presented to his native town his own conchological collections and library

THE Geologists' Association will hold a conversazione on Friday, November 4, in the Library of University College, Gower Street Among the exhibits will be a series of photographs of the recent eruption of Mount Etna. These will be shown by Mr F W Rudler

MR M C POTTER has been appointed to the Chair of Botany at the College of Science, Newcastle on-Tyne

THE annual meeting and conversazione of the Postal Microscopical Society took place at the Holborn Restaurant on the 20th inst There was a good attendance, and many microscopical specimens were displayed An address on polarized light was delivered by Mr G H Bryan, the president

THE following lectures will be given at the Royal Victoria Hall on Tuesday evenings during the coming month —Nov 1, Prof A H Green, "Coal, what it is and how it was made," Nov 8, W D Halliburton, M D., F R S., "The history of some famous epidemics," Nov 15, Hermann H Hoffert, D Sc., "Electric sparks and lightning flashes," Nov 22, Prof Hall Griffin, "Among the hills of Asolo an illustrated account of the poem 'Pippa Passes'"

NATURALISTS who visit the Zoological Society's Gardens should not fail to go to the Insect House and see the Pratincole, which has lately been received, and is kept in a cage in this building So far as we know, it is the first example of this curious form of plover that has ever been seen in captivity The specimen in question does not, however, belong to the Pratincole of the south of Europe (*Glareola torquata*), which has sometimes occurred in this country, but to an allied African species—the Madagascar Pratincole (*Glareola ocularis*). The bird was obtained near Mombasa, in Eastern Africa, and presented to the society by Mr. R. MacAllister. It was carefully brought home, along with many other interesting specimens, from Zanzibar and the adjoining mainland by Mr Frank Finn, F.Z.S., on his return from his recent expedition to that country

A CORRESPONDENT from Tangier writes that during the recent mission to Fez of Sir Euan Smith, Mr. Walter H Harris and Mr. Carleton, the interpreter, were informed by a cherif from Tafilelt, cousin of the Sultan, and Governor over an extensive district, that there is no question as to the existence of dwarf tribes down the Dra, where they are very numerous Sir Euan Smith was told of this statement, and probably had a talk with him Mr Harris intended to have taken a trip down the Dra to Akka, but was convinced from what he heard that such a trip would be an act of suicide He however believes that he can get full information as to the dwarfs, and perhaps photographs, without going so far, and he has just left for a trip to the interior for two months Herr E G Donnenberg, who has been for some years engaged in pushing German trade in Marocco, and every year visits the principal cities, says that a year ago he saw in Marocco city from half a dozen to a dozen dwarfs, one of whom was accompanied by a dwarf wife They were about 4 ft high, and robust and well made, and were certainly not Moors who had been dwarfed by rickets, as they differed from the ordinary population of Marocco in appearance Herr Donnenberg's address is Tangier, and he states that he is ready to answer any queries that may be sent to him, but that he cannot add anything to what is here stated, as he did not ask any questions as to the dwarfs, not knowing that they were of interest He goes to Marocco city before long, and will make it a point to find out all he can respecting them

DURING the latter part of last week a depression lay over the North Sea, which spread both in size and intensity, causing strong northerly winds all over this country, with heavy gales and snowfall in Scotland and the east of England, while in the southern districts the weather was fine and bright The temperature was unusually low for the time of year, the mean temperature having in fact been considerably below the average on each day since the beginning of the month The daily maxima have varied from 40° in the north to 52° in the south, with sharp frosts at night On Sunday night the grass thermometer in London fell to 20°, while 25° in the shade were registered the next night in the north and west During the early part of the present week, the area of high pressure in the west gave place to a depression, which arrived from off the Atlantic, causing cold easterly winds in the south with very heavy rains in the south-west of England, the weather over Scotland improved, although some snow showers continued to fall on the east coast The *Weekly Weather Report*, issued on the 22nd instant, showed that the temperature of that week was much below the mean, the deficit ranging from 5° to 7° Rainfall exceeded the mean in the east and north-east of England, but in all other districts there was a deficit In the south west of England there was still a deficit of about eight inches since the beginning of the year.

WE recently drew attention to a new meteorological journal published in Paris, we now note the appearance of a similar publication at Vilafranca del Panadés, in Spain It is published on the 15th of each month, and contains a series of short elementary articles and notes, occupying only twelve small octavo pages We hardly expect it to find many readers in this country, but hope it may awaken more interest in the subject in Spain, where practical meteorology is not at present on the same level as in other European countries.

THE Director of the Lyons Observatory, M C. André, has published, under the title, "Relations des Phénomènes Météorologiques déduites de leurs Variations Diurnes et Annuelles," the results of the meteorological observations taken there for ten years ending 1890 The text and plates together occupy one hundred and sixty-eight large octavo pages, and, this volume will be found to be full of interest and instruction, to any one wishing either to take observations or to work up

the results. The title is well chosen, for the work treats of the relations which connect the different phenomena; it also gives all necessary precautions for ensuring the accuracy of the observations. Particular attention is paid to the important subject of diurnal and annual variations of the different elements, and to the various points to be noted, while the different theories of atmospherical electricity are explained at considerable length.

A BEAUTIFUL and instructive lecture experiment, illustrative of the conditions of the heated atmosphere which give rise to the mirage, is described by MM. J. Macé de Lepinay and A. Perot, in their "Etude du Mirage," which appears in the *Annales de Chimie et de Physique*. Water is poured into a long rectangular trough with glass slides, and covered with a layer of alcohol about 2 cm. thick, containing a trace of fluorescene. After a few hours, during which the alcohol diffuses slowly through the water, a flat beam of light is sent through the mixture at a very slight inclination to the horizon. Under these conditions a kind of garland of light is seen to traverse the liquid, due to a series of curvilinear deflections or "mirages" in the less highly refractive water below and total reflections at the upper surface of the alcohol.

PROF. W. CROOKES and Prof. W. Odling, in their report on the London Water Supply for the month of September, are able to give an excellent account of the 182 samples which they analyzed. All were found to be perfectly clear, bright, and well filtered. In respect to the smallness of the proportion of organic matter present, the character of the water furnished by the seven companies continued to be entirely satisfactory, the mean amount of organic carbon in the Thames derived supply, for example, being ·118 part, and the maximum amount in any single sample examined being but ·145 part, in 100,000 parts of the water—numbers practically identical with those of the previous month, or ·115 part for the mean, and ·152 part for the maximum, amount. The average of the past six months, in the case of the Thames derived supply, has amounted only to ·116 part of organic carbon in 100,000 parts of the water, with a maximum, twice met with, of ·152 part in any individual sample. The authors of the report do not expect that with the coming on of autumn and winter this low average will be much longer sustained. They note that the water supply to London is habitually at its best during the hot season, when a high quality of the supply is more especially called for.

AN interesting report on the Congress of the Library Association of Great Britain, held at Paris last month, was read on Tuesday before the Salford Royal Museum and Free Libraries' Committee. It was prepared by Mr. Alderman W. H. Bailey, who had naturally a good deal to say about the Paris Free Libraries. The governing bodies of almost all these institutions consider that there are many reasons why the libraries should be closed in the daytime when respectable artizans are engaged in earning their living. Books are therefore given out for two hours every evening of week days, generally from eight to ten o'clock, and also for two hours every Sunday morning. Mr. Bailey and the other members of the Congress were delighted with the Paris Libraries of Industrial Art, to which they devoted much attention. These Libraries—which, like the Free Libraries, are under municipal control—are in the artizan districts of Paris. Books, patterns, prints, drawings, and photographs are lent out. "Not only do house decorators," says Mr. Bailey, "find designs and books relating to work, but fan painters, porcelain modellers, designers of iron and bronze gates, medieval metal workers, cabinet makers, builders, and all workers in the constructive as well as the decorative arts may here find stimulus and draw inspiration from the wealth of examples on the shelves and walls." Free lectures are delivered in the winter on industrial art and science, and on the designs, books, and models in the Libraries.

VARIOUS experiments which are being made in France with a view to the improvement of the potato have attracted a good deal of attention in Australia. According to a statement recorded in the *Agricultural Gazette of New South Wales*, no fewer than 110 growers have obtained from a variety known as "Richter's Imperator," from twelve to twenty tons per acre, while the average is over fourteen tons to the acre. The Minister of Agriculture in New South Wales has approved of one hundredweight each of this and any other three sorts highly reputed in France being imported for experimental purposes.

AT a recent meeting of a society of French agriculturists, it was stated by Baron Bertrand-Geslin, that ten or twelve years ago a disease appeared among the chestnut trees in central and north western France, and destroyed them in great numbers. The wood, moreover, could not be utilized for heating purposes. At this juncture an enterprising person appeared, who bought up large quantities of this dead wood and sent it by canal to Nantes, where he had works established for utilizing it in the tanning of leather. Chestnut wood contains, in fact, 5 to 6 per cent. of tannic principles, whereas oak contains only 3 or 4. By the means adopted in these works the principles are concentrated in a sirupy liquid of great strength. This establishment has become very important; it absorbs annually thirty to thirty-five million kilogrammes of wood of these dead chestnuts from three departments traversed by the canal from Nantes to Brest, and expends about 120,000 francs per annum, a considerable reduction of the loss sustained by the landowners. It was mentioned, however, by M. Paul Becquerel, in reply to a question as to competition of the new extracts with bark, that those extracts, which are products allied to tan, do not give the same results, or leather of such good quality, and many tanners who have used them have returned to the old methods of tanning.

DR. R. MUNRO contributed to the *Times* of Monday a long and most interesting account of the recent discovery of an ancient lake-village in Somersetshire. The site is about a mile north of Glastonbury. Before excavations were begun, there were sixty or seventy low mounds, rising from one to two feet above the surrounding soil and measuring from twenty to thirty feet across. That the mounds were of archæological interest was first suspected by Mr. Arthur Bulleid, who began to excavate some of them during the present summer, and was soon rewarded by making striking discoveries. Woodwork corresponding to that of the crannogs of Scotland and Ireland has been exposed, and among the objects which have been recovered are some of bronze, a few of iron, and various specimens of pottery. Mr. Bulleid has also dug out "a splendid canoe neatly formed out of the trunk of a tree." This was found about a quarter of a mile from the settlement. It would seem that the inhabitants, after a period of long occupancy, indicated by a succession of superimposed hearths, were flooded out of their homes, for an accumulation of flood soil now covers the whole meadow to the extent of 12 inches to 18 inches in depth. The surrounding district is richly cultivated, but, in looking over an old map of the date of 1668, Dr. Munro found that it contained a lake called the "Meare Poole," into which three streams debouched, and from which the site of the present discovery could not be far distant. He suggests that this lake had larger dimensions in earlier times, and that when the settlement was founded the locality was a shallow lake or marsh. The old map represents the district lying immediately on the north-west borders of the "Meare Poole" as inhabited by the Belgæ. Dr. Munro is strongly inclined to think that the settlement belongs to the so-called Late Celtic period. This he would simply call the Celtic period, for there is no evidence, he believes, of earlier Celtic remains in Britain

than those known as Late Celtic. "The style of art," he says, "which controlled the manufacture of Late Celtic objects involves such an enormous advance in metallurgical skill over that of the Bronze Age, that it is impossible to suppose the two are connected by any evolutionary stages in this country. From the standpoint of archæological research this interval, or rather *hiatus*, can only be bridged over by the supposition that the people who owned Late Celtic remains were newcomers and conquerors in Britain." Much light will no doubt be thrown on the question by the further exploration of these remarkable mounds.

A LIVELY correspondence on the subject of birds *versus* insects has been going on in the Malta papers. According to the *Mediterranean Naturalist*, the enormous increase of insectiferous pests during the last few years has caused the agricultural industries to decline to an alarming extent, and it is urged that the evil has now increased so much as to call for legislation. In the Maltese Islands there are no laws for the protection of birds, and, the lower classes of the Maltese being keen sportsmen, no opportunities are allowed to either the migratory or the indigenous species of increasing.

IT was observed by Prof. Voit that when dogs were fed exclusively on bread they daily lost albumen, though not weight, the body becoming more watery and the hæmoglobin of the blood diminishing. This matter has been recently further investigated in his laboratory by Herr Tsuboi. Of three rabbits, one was fed with milk, rolls, and some hay, another with much hay, the third with potatoes. The last had more water in muscles and blood, and less hæmoglobin than the first. In another experiment (with like results) one of two cats was fed with meal and fat, another with bread and some meat extract. Again, three rabbits were fed with potatoes, the first with iron added, the second with serum, the third with blood. The last was found to have most solid matters in muscles and blood, and most hæmoglobin. It is not (the author points out) the amount of food by itself alone that determines the result, otherwise, in the fasting state, the hæmoglobin would be least, whereas it is the same as with good feeding. It is rather the insufficient composition of the food, the too small amount of albumen, with excess of starch-flour that has the injurious effect.

THE phosphoroscope of Becquerel is a well-known instrument, enabling one to observe the phosphorescence of some substance when the exciting light is gone. It is designed to be used with sunlight. M. Lenard has devised an instrument (*La Nature*) for use with the electric spark. To the armature of a Foucault interrupter in an induction coil, is attached a light wooden rod, having at its end a piece of blackened pasteboard, which is thus driven up and down before a spark-interval between two brass knobs connected with the coil and a condenser (added to intensify the spark). The body to be examined is placed close behind the interval, so that it is uncovered very quickly after the spark passes. Some curious phenomena are observed. The short duration of the spark makes the screen seem at rest, and some thousandths of a second after one sees a luminous body behind where it was, so that at first sight one might think the screen opaque to the spark, but transparent for the phosphorescent light, an illusion due to the persistence of luminous impressions. Some bodies, such as various carbonates of lime, behave very much alike in this apparatus and in Becquerel's; some are favoured in the latter, and on the other hand, crystals of arragonite, which are invisible after solar illumination, give a faint reddish light after the spark. Various experiments are described. The most curious results are furnished by the remarkable substance, asaron. In a Crookes tube this gives a bright light, it gives also a distinct glow in the ultraviolet spectrum of the spark, but in the phosphoroscope it is absolutely dark. The vibratory movement ceases immediately with the excitation.

THE new number of the *Internationales Archiv für Ethnographie* (Band v., Heft 4) consists mainly of the first part of what promises to be an elaborate paper (in German) on the inhabitants of the Nicobar Islands, by Dr. W. Svoboda. In October, 1886, while the German corvette, *Aurora*, lay in the harbour of Nangcauri, Dr. Svoboda had many opportunities of seeing the natives, and Mr. F. H. Man gave him facilities for the thorough study of a splendid collection of ethnographical objects from various parts of the group. Afterwards he extended his knowledge of the subject by reading books which dealt with it, and by visiting the ethnographical museums of Berlin and Vienna. The results he is now bringing together, and those of them embodied in the present contribution show that he is not only a good observer but that he knows how to state facts clearly and concisely. The paper is illustrated with coloured plates and woodcuts.

THE British Institute of Public Health has now an official quarterly journal, called *The Journal of State Medicine*. It is published by Charles Griffin and Co. The second number has appeared, and contains original papers on the following subjects—lead in articles of food, by Prof. William R. Smith; points in the ætiology of typhoid fever, by Edmond J. McWeeney; chemical bacteriology of sewage, by W. E. Adeney; and new method of sewage purification, by W. Kaye Parry.

A NEW and revised edition of the late Prof. Moseley's well-known "Notes by a Naturalist on H.M.S. *Challenger*," has been issued by Mr. John Murray. It includes an excellent portrait, which vividly reminds us of the great loss inflicted on science by his premature death.

MESSRS. WHITTAKER AND CO. have published the first part of a work entitled "Dissections Illustrated: A Graphic Handbook for Students of Human Anatomy," by C. Gordon Brodie. The plates are drawn and lithographed by Percy Highley. The work will be completed in four parts. The present part deals with the upper limb, and includes seventeen coloured plates.

A SECOND edition of "A Short Manual of Inorganic Chemistry," by Dr. A. Dupré and Dr. H. W. Hake (Charles Griffin and Co.), has been issued. The authors have endeavoured to bring the statement of facts up to date without increasing the bulk of the work, and to remove those errors to which their attention has been drawn.

A RE-DETERMINATION of the mechanical equivalent of heat has been made by M. C. Miculescu at the Sorbonne. An account of the method appears in the *Annales de Chimie et de Physique* for October. The method was that of water friction at constant temperature. The liquid was enclosed in a cylindrical vessel with three envelopes. Water was kept circulating round the innermost one at such a rate that the difference of temperature of the water at entrance and exit was constant as measured by a thermopile. The heat thus derived from the water inside could be estimated by the quantity of water passed through. The water inside was stirred by vanes mounted on an axial shaft kept rotating by a gramme machine of 1 horse power running at 1200 revolutions per minute. The expenditure of work was measured by making the whole apparatus its own dynamometer. It was suspended so as to turn round the common axis of the stirrer and the motor. The resistance met with by the former tended to turn the apparatus in the direction of revolution of the latter. It was kept stationary by a weight attached to an arm exerting a measurable couple. The mean of 31 values ranging from 425·21 to 427·12 was 426·70 in kilogram-metres

per calorie, or 4 1857 × 10^7 ergs For the normal scale of the hydrogen thermometer this would be 426 84

A NEW and very convenient method of preparing acetylene gas is described by M Maquenne in the current number of the *Comptes Rendus* A short time ago the same chemist succeeded in preparing a comparatively stable compound of carbon with the metal barium, BaC_2, by heating powdered retort-charcoal with barium amalgam in a current of hydrogen Upon bringing this compound in contact with water a violent action was found to occur with evolution of almost pure acetylene gas On account, however, of the troublesome nature of the operations of procuring barium amalgam and preparing from it the new compound, together with the very small quantities of the latter eventually obtained, this mode of preparing acetylene was only of theoretical interest, and not suitable as a laboratory method of preparation M Maquenne now describes a new process for preparing barium carbide, by means of which large quantities may very readily be procured in a few minutes, and from which correspondingly large volumes of acetylene may be derived The principle of the method consists in reducing barium carbonate by metallic magnesium in presence of carbon An intimate mixture is first made of barium carbonate prepared by precipitation, powdered metallic magnesium, and calcined retort-carbon Convenient amounts are twenty six grams of barium carbonate, ten and a half grams of magnesium, and four grams of charcoal This mixture is then introduced into an iron bottle of about seven hundred cubic centimetres capacity, furnished with a tube, also of iron, thirty centimetres long and two centimetres internal diameter The iron bottle is then heated in a gas furnace which has previously been raised to a red heat At the expiration of about four minutes an energetic reaction occurs, accompanied by the projection of brilliant sparks from the mouth of the tube The apparatus should then at once be removed from the furnace, the end of the tube stopped, and the bottle and contents rapidly cooled by the external application of cold water The product may then be extracted, when it is found to consist of a mixture of magnesia with 38 per cent of carbide of barium, a little excess of carbon, and a trace of cyanide formed at the expense of the atmospheric nitrogen The reaction accords very closely with the equation —

$$BaCO_3 + 3Mg + C = BaC_2 + 3MgO$$

Carbide of barium may be preserved for an indefinite time in a dry atmosphere. It is a grey, porous, and very friable substance When heated to redness in the air it burns with a vivid incandescence It is also capable of combustion in chlorine, hydrochloric acid gas, and vapour of sulphur In order to prepare acetylene from it the powder is most conveniently placed in a small flask fitted with a doubly-bored caoutchouc stopper, carrying a dropping funnel containing water, and a delivery tube. The moment water is allowed to drop the equivalent quantity of acetylene gas is evolved in accordance with the equation —

$$BaC_2 + 2H_2O = Ba(OH)_2 + C_2H_2.$$

The delivery of the acetylene may be regulated with great nicety by suitable adjustment of the stopcock of the dropping funnel The acetylene thus prepared possesses the further advantage of being remarkably pure, containing 98 per cent of C_2H_2. It is interesting to learn that by allowing a stream of this pure acetylene to pass through a long heated glass tube for a few hours several grams of synthetical benzene have been accumulated by M Maquenne.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♀) from India, presented by Mr W. F Faulding, a Buffon's Touracou (*Corythaix buffoni*) from West Africa, presented by Mr A. L. Jones; two Double banded Sand Grouse (*Pterocles bicinctus* ♂ ♀) from Senegal, presented by Mr H H. Sharland, F Z S, a Gannet (*Sula bassana*), British, presented by Dr Davis, a Roseate Cockatoo (*Cacatua roseicapilla*), a King Parrakeet (*Aprosmictus scapulatus* ♀) from Australia, presented by Mrs Addiscott, four Alligators (*Alligator mississippiensis*) from the Mississippi, presented by Mr John Terry, two Thick billed Seed-eaters (*Oryzoborus crassirostris*), a Tropical Seed Finch (*Oryzoborus torridus*), a Saffron Finch (*Sycalis flaveola*), a Bluish Finch (*Spermophila cærulescens*) from South America, a Puff Adder (*Vipera arietans*) from West Africa, deposited

OUR ASTRONOMICAL COLUMN

COMET BARNARD (OCTOBER 12) —An *Astronomische Nachrichten* circular note gives the following elements and ephemeris, computed from observations made on the 16th, 17th, and 18th of this month —

Elements

T = 1892 Nov 12 745 Berlin M T

ω = 168 49

☊ = 220 50

i = 21 39

log q = 0 03669

Ephemeris Berlin Midnight

1892	R A h m	Decl ° ′	Log Δ	Br
Oct 25	20 6 6	+7 47		
27	13 5	6 51	9 6825	1 46
29	21 5	5 52		
31	29 8	4 51	9 6609	1 66
Nov 2	38 7	3 47		
4	48 2	2 40	9 6377	1 87
6	20 58 3	1 29		

As the brightness at the time of discovery is taken as unity, it will be noticed that the comet is quickly gaining in intensity, the value for November 8 being 2 08 Br Its position on the 31st lies in the southernmost part of the constellation of the Dolphin, forming very nearly an equilateral triangle with α Aquilæ and β Delphini

DISCOVERY OF THREE NEW PLANETS BY PHOTOGRAPHY — M Perrotin has communicated to the French Academy an account of the discovery of three small planets by M Charlois, of the Nice Observatory, by the aid of photography The apparatus employed consisted of an Hermagis portrait lens of 15 cm aperture and 80 cm focal length, mounted provisionally on M Loewy's *equatorial coudé* The instrument was being employed for the photography of the region of the ecliptic With exposures ranging from two hours and a half to three hours, the eight negatives obtained since September 12 cover a region 80° long and 10° broad, and show all the stars visible through the 38 cm refractor A careful examination of the plates reveals the presence of three unknown and eight known planets The former, now known under the names 1892, D, E, and F, are all of about the twelfth magnitude.

RUTHERFURD MEASURES OF STARS ABOUT β CYGNI — Mr Harold Jacoby, in No 4 of the *Contributions from the Observatory of Columbia College, New York*, presents us with the reduced results of the measures of the plates containing the group of stars surrounding β Cygni The method of measurement was exactly the same as that employed in the case of the Pleiades plates, but that of reduction has received some slight modification For instance, the measures of the eastern and western impressions have not been separately dealt with, but their mean has been taken, and the reduction continued, using this mean as a single observation. As the accuracy of these measurements depend on the exactitude of the scale value determinations to a very considerable extent, it is satisfactory to hear that this value has remained materially the same for a very long period The largest and smallest values recorded in the Pleiades plates were 28″ 0167 and 28″ 0066, the mean value amounting to 28″ 0124, and it is

his last-mentioned value that has been used in the above reductions The probable error of these determinations is then ±0″ 00071, which corresponds to ±0″ 025 per 1000″ But Mr Jacoby does not think that the average uncertainty of the final places exceeds 0″ 15 on account of scale value While comparing the Rutherfurd stars with those of Argelander, he found that four stars from the latter were lacking, while they were recorded on the original negatives of the former Observations made this year showed that three wer visible, while the fourth (No 28), which was quite close to No 27 on the Rutherfurd negatives, was this year "only a sort of elongation of No 27" On the other hand, the following of Argelander's stars were absent from the plates —

A NEW VARIABLE STAR —In *Astronomische Nachrichten*, No. 3124, Prof Pickering announces the discovery of a new variable star in Aries by Prof Schaeberle The fact of this star being a variable was first noted when, on an examination of two plates taken December 18 and January 24, 1891, it was found that on the former it appeared of the 9 5 magnitude, while on the latter it was absent altogether Recent visual observations have shown, however, a star of the eleventh magnitude in the exact position of the suspected variable, and this has been confirmed by means of photographs From photographs of the same region, taken since October 31, 1890, the magnitudes recorded have been 9 6, 10 2, 11 0, less than 11 7, 10 1, 10 0, 10 4, 10 3, and 10 9 The star s position for 1900 is given as

R A 3h 5 5m Decl + 14°24′

JUPITER'S FIFTH SATELLITE —It hardly ever happens that, after a discovery of any importance has been made, there are not a few "claimants" who wish to annex it as their own This is the case with Prof Barnard's discovery of the fifth moon to Jupiter, but the advantage he possesses over these said "claimants" is, we might say, infinite, for it is only with such an instrument as that at the Lick Observatory that this "mite" of a satellite can be observed with success One of the despatches in which one "claimant's" views were put forth, had the audacity to insinuate that Prof Barnard was directly inspired to this discovery by information contained in a letter sent to the Observatory We are glad to see that Prof Barnard deals with these "claimants" as they deserve, and we hope it may be a lesson to others who wish to assert their priority without good and sufficient reasons for doing so

As an illustration of the difficulty of observing this satellite, we may mention that Prof Young, in a letter to Prof Barnard, says that although he has used a 23 inch Clark, which is an instrument as nearly perfect as can be made, he was not rewarded with success.

THE SPECTRUM OF NOVA AURIGÆ —Herr E von Gothard, of the Observatory at Herény, has taken a very successful photograph of the Nova spectrum, the results of which he communicates to *Astronomische Nachrichten*, No 3122 The instrument used was a 10½-inch reflector with a 10-inch objective prism, and the exposure given amounted to 45 minutes The spectrum shows six lines, and a comparison with the spectrum of the ring nebula and the Wolf-Rayet stars presented a remarkable concordance, the first failing only in the second Nova line, and the second differing only with regard to the intensity of the individual lines The following table shows this somewhat more clearly —

	I	II	III	IV	V	VI	VII
Nova	6	1	10	5	3	4	—
G. C 4964	8	2	10	6	6	8	—
Ring nebula	8	—	5	2	7	6	10

The wave lengths of the lines are, we are sorry to say, not inserted.

"JUPITER AND HIS SYSTEM" is the title of a small book recently published by Mr Stanford, and written by Miss E M Clarke. The authoress has brought this book out at a time when this planet is receiving most attention, for was it not in opposition, shining with exceeding brightness, on the 12th of this month? One great point about this little monograph is that facts throughout have been strictly adhered to, so that the reader is presented with the true state of the planet as we know it The information is well up to date, as for example the mention of the new satellite, and the book is written in a popular yet accurate style One thing that calls for attention is the price (one shilling), which could doubtless have been halved

GEOGRAPHICAL NOTES

MR J Y BUCHANAN, F R S, is this term delivering a course of lectures on Oceanography in Cambridge University It is satisfactory to know that the lectures are better attended than has been the case since the foundation of the Geography lectureship, and that the greater number of those present this term are undergraduates

MR JOSEPH THOMSON has submitted to the British South Africa Company the report of his journey to the Lake Bangweolo region, made last year, which ill health has prevented him from preparing sooner He speaks of Northern Zimbesia generally as a region of great possibilities It is a plateau rarely less than 3500 feet high, with a climate in which Europeans should find no difficulty in living for several years at a time It is well suited for cattle rearing and for planting, and there is an appearance of mineral wealth Like the rest of tropical Africa, the land must be occupied and cultivated, and the natives must be trained to industry before commercial results of any importance can be obtained

THE special meeting of the Royal Geographical Society to hear Captain Lugard s paper on Uganda will be held on Thursday, Nov 3, at 8 30 p m On account of the great popular interest at present being manifested in the region of the Equatorial lakes, no extra tickets can be issued by the Society, as the attendance of Fellows and their friends will probably more than fill the hall

THE new number of *Petermann's Mitteilungen* contains some articles of considerable interest Dr W Ruge, son of the well-known geographer, Dr Sophus Ruge, contributes a short but learned treatise on the geography of Asia Minor, which combines literary research with personal exploration Dr Ernst H L Krause produces an interesting map of North Germany, showing the distribution of forests and the most common species of trees during the Middle Ages This work is accomplished mainly by the consultation of old records, and the examination of the remains of old forests and very ancient trees The study of history is greatly helped by such a map, and the influence of increasing density of population and extending cultivation of farm crops is brought out strikingly by comparison with a map of the vegetation at the present day. Dr Karl Sapper's description of Lake Yzabal in Guatemala is also worthy of note

GEIKIELITE AND BADDELEYITE, TWO NEW MINERAL SPECIES

VARIOUS pebbles were lately brought to this country by Mr. Joseph Baddeley, who has been acting as manager of a Gem and Mining Company in Ceylon They had been picked up by him in the neighbourhood of Rakwana (Rackwanné) at various times, and had then attracted his special attention by reason of their high specific gravity Their real nature not being evident on inspection, Mr Baddeley, when invalided, brought them home to England for identification

One kind of pebble, kindly analyzed for him by Mr Claudet, was found to be essentially a tantalate of yttrium

Pebbles of another kind were taken to the Museum of Practical Geology in Jermyn Street for examination The external characters being found by Mr. Pringle insufficient for the determination of the species, the pebbles were handed over to Mr Allan Dick for chemical investigation Quantitative analysis proved the mineral to be essentially magnesium titanate ($MgTiO_3$) and chemically analogous to Perofskite, calcium titanate ($CaTiO_3$) To this interesting new species Mr Dick, in a paper read before the Mineralogical Society in June, gave the name Geikielite, in honour of Sir Archibald Geikie, F R.S, Director General of the Geological Survey, in whose laboratory the analysis had been made.

As described by Mr Dick, Geikielite has a specific gravity

3 98 its hardness (6 5) is between that of quartz and felspar It has a perfect cleavage, with a splendent metallic lustre, and an imperfect cleavage nearly at right angles to the former The pebbles themselves show no remains of crystal-faces, are bluish-black in colour, and opaque, but thin cleavage-flakes, when seen in the microscope, have a peculiar purplish red tint, and in convergent polarized light show a uniaxal figure, of which the axis is just outside the field of vision When digested with hot strong hydrochloric acid the finely powdered mineral is slowly decomposed, and the titanic acid separates out In strong hydrofluoric acid complete solution takes place in a few hours The mineral is infusible with the blowpipe fused with microcosmic salt it gives the characteristic reaction of titanic acid, notwithstanding the presence of a small proportion of oxide of iron

Shortly after Mr Dick's paper had been read, Mr Baddeley courteously offered to allow me to select a single pebble for the British Museum Collection out of his small store of the mineral, the remaining ones being required by him for sending as samples to be used by searchers in Ceylon But this store, small though it was, consisted of more than one kind of pebble, the close similarity of aspect being due to friction against a bit of graphite which was with them On this heterogeneity being pointed out, Mr Baddeley allowed me to take not only the promised pebble of Geikielite, but also those three pebbles which, not being Geikielite, were useless as samples of that mineral One of the three fragments proved to be garnet a second was ilmenite—both of them common minerals—but the third, a fragment of a crystal still retaining some of its faces, presented characters which give it unusual interest

The fragment, which weighs just over three grains, is black and opaque, and has the general aspect of columbite, its extremely high specific gravity (6 02) and its hardness (6 5) are also suggestive of that mineral In microscopic fragments it transmits light and is dichroic, changing from a greenish yellow to brown with the plane of polarization of the light, the fragments, when examined in convergent polarized light, show a biaxal figure, the apparent axial angle being large (near 70), the character of the double refraction is negative There is only one well developed zone of crystal faces remaining on the fragment, it consists of two rectangular pairs of parallel faces (pinakoids) and of four prism faces (*m*), the faces of one pinakoid (*a*) being much larger than those of the other (*b*), the angle *am*, as determined by means of reflection, is about 44°, but the images of the signal are multiple and wanting in definition, the dispersion of the optic axes indicates that the system of crystallization is mono symmetric Two other faces form a re-entrant edge parallel to the larger pinakoid, and inclined to the edges of the well developed zone, but whether this is really due to twinning or not is far from evident

The above set of external characters suggested that the fragment does not belong to any of the known species, and it became necessary to determine its chemical behaviour, but on account of the necessity of preserving the natural faces of what might possibly be an unique fragment, this was a process demanding great caution, fortunately, the behaviour was such that it was practicable to determine the precise chemical nature of the mineral without interference with the crystal faces, or, indeed, any appreciable destruction of material It will be sufficient to state here the result, namely, that the material is no other than crystallized zirconia, the technical details relative to both this mineral and Geikielite will be given in the next number of the *Mineralogical Magazine* It is remarkable that, notwithstanding the wide prevalence of zircon itself (silicate of zirconium), the natural occurrence of the oxide of zirconium has not previously been noticed For this new species I beg to suggest the name Baddeleyite, in recognition of the services of Mr Baddeley to mineralogical science, but for his close scrutiny of the mineral products of Rakwana, the existence of the above remarkable species would doubtless have long remained unknown

L. FLETCHER

NEW BRITISH EARTHWORMS

THE additions which I have been able to make to our list of indigenous Annelids during the past two years fall naturally into two groups. There are, first, two species which are new to science, and are therefore at present known only as British species. In addition to these there are several species which, while they have been recorded for various Continental stations, have never been found in England till I discovered them among the gleanings which I have passed under review from nearly every part of the country I shall first of all give a description of the new species

1 *Lumbricus rubescens*, sp nov

This is a genuine Lumbricus in the strictest sense of the word, as it is understood by all those who adopt Eisen's analysis of this group of worms published in 1873 The lip forms a perfect "mortise and tenon," with the first ring or peristomium, and the girdle consists of six segments, four of which bear the *tubercula pubertatis* I first discovered it in Yorkshire in 1891, and have since then taken it myself at Hornsey in Middlesex, Tunbridge Wells, and Dallington in Sussex, while more recently I have received it from Avonmouth in Gloucestershire

In general appearance it resembles the common earthworm (*L terrestris*, L), as recently defined and differentiated It is slightly smaller in size, but frequents similar haunts, and might in most respects easily be mistaken for the type It has the male pores on segment 15 on raised, pale papillæ, but the girdle invariably commences on segment 34, and extends to the 39th, while the band which forms the *tubercula pubertatis* extends over 35 to 38 Its general form and appearance will

FIG 1—*Lumbricus rubescens*, Friend Natural size

be best understoood by the study of the woodcut (Fig 1) Internally it does not differ from the other Lumbrici, but the dorsal pores commence between [illegible] This makes the fourth true Lumbricus found in the British Isles, and it may be a convenience to collectors if I append a tabular statement of the features by which each is distinguished from the other

Chart of the Genus Lumbricus

Lumbricus	Segments occupied by the Girdle	Tubercula	First dorsal pore	Papillæ	Spermatophores	Average length	No. of segments
Terrestris, Linn	32—37	33—36	[illegible]	15, 26	[illegible]	5 inches	150—200
Rubescens, Friend	34—39	35—38	[illegible]	15 28	32/33	4 inches	120—150
Rubellus, Hoffm.	27—32	28—31	[illegible]	none	[illegible]	3 inches	110—140
Purpurous, Eisen	28—33	29—32	[illegible]	10 (11)	[illegible]	2 inches	100—120

It will be seen that there is now a regular series in relation to the first dorsal pore, [illegible], as well as in the matter of length from 2 to 5 inches and upwards, and number of segments from 100 to 200 or thereabouts These points are worthy of note in the study of the evolution of worms.

2 *Allolobophora cambrica*, sp nov

This species, which I have since found in several parts of England, first came to my notice as a new species from Wales Hence the specific name I had previously assigned it to one or other of the related species, but eventually found on dissection that it was quite distinct from every other worm of which I have been able to obtain any description

At first sight *A cambrica* has all the appearance of the mucous worm (*A mucosa* Eisen) Its average length in spirits is about 2 inches, but when living, and moderately extended, it measures three inches It is of a fleshy colour, with a somewhat transparent skin, so that the blood vessels can be well observed between the girdle and the head The dorsal pores are conspicuous in specimens which have been placed in methylated spirits, the first occurring between segments 4 and 5 The

[1] Vejdovsky and others mention the occurrence of Spermatophores on these species, but do not state the position The point is one which should not be ignored

setæ are in four couples, the individuals of which are near each other The girdle covers segments 29 to 37, while 31 33 35 bear each a pair of tubercules (Fig 2) as in the green worm

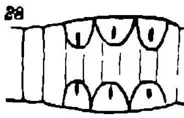

FIG 2—Diagram of girdle of *A cambrica*, Friend, showing tubercula on ventral surface

(*A chlorotica*) There are two pairs of spermathecæ in segments 10 and 11, opening anteriorly, the male pore on segment 15 is borne on prominent papillæ, which cause the adjoining segments to appear swollen (Fig 3) It is a very clean worm,

FIG 3—*Allolobophora cambrica*, Friend Natural size

exudes but little mucus as compared with the green worm, the tail is much longer than in that species, which, in the matter of girdle and tubercules, it most nearly resembles It will be well to tabulate the points in which this worm resembles and differs from its nearest allies

Allolobophora cambrica resembles

Allo. chlorotica	*Allo mucosa*
in position and appearance of male pore, girdle, and *tubercula pubertatis*	in colour, shape, size, activity, position of first dorsal pore, and appearance of male pore

It differs

in mucus, transparency, length and shape of tail, and number of spermathecæ	in position and shape of girdle, position of *tubercula pubertatis*, and general outline

Tabular View

Allolobophora	Segments occupied by the Girdle	Tubercula	First dorsal pore	Spermathecæ	General observations.
Chlorotica	29—36	31 33 35	[illegible]	9 10 11	Dirty green, opaque, sluggish, and grub like, exudes much mucus
Mucosa	26—32	29 30 31	[illegible]	10 11	Flesh coloured active, with transparent epidermis little mucus
Cambrica	29—37	31 33 35	[illegible]	10 11	Closely resembling *A mucosa* in general features

When our knowledge of the hybridity of worms is more perfect, it is possible that some new light will be thrown upon such coincidences as these I have received the worm from, or collected it in, Nottinghamshire, Hertfordshire, Yorkshire, and Montgomeryshire I believe I have also found it in Westmorland and elsewhere, but entered it either under one or the other of the two species which it so closely resembles

Next, we have to note the worms which are new to Britain, though not new to science These all fall under the genus Allolobophora, and several of them are so well marked that I have, in some recent articles on this subject, revived Eisen's subgeneric term Dendrobæna, and placed under it about half a-dozen species of tree-worms which are more or less widely distributed in this country

The tree-worms are small, hardy, and active, the lip is usually very delicate, and appears to be used, not only as a sucker and boring agent, but also as a tissue dissolver, probably by the use of a special saliva. The setæ are usually in eight almost equidistant rows, and the lip cuts more or less deeply into the first ring The type of this group is *Dendrobæna Boeckii*, Eisen, which has been the subject of endless confusion The true species, following the diagnosis of Eisen, is very rare in England, and I have found it nowhere but in Airedale and Wharfdale, Yorkshire I believe all the other records which have been given by other writers should be assigned to the much more common and widely distributed species known as *Allolobophora subrubicunda*, Eisen This worm belongs to the same group, but lives among vegetable *débris* as well as beneath the bark of decaying trees Another species (*A arborea*, Eisen) is found only in dead timber I have specimens from Cumberland, Gloucestershire, Yorks, and Sussex It is one of the prettiest and neatest worms indigenous to this country Nearly related to this is another (*A celtica*, Rosa), which, while it prefers trees, will thrive among decaying vegetable matter. I first found it at Langholm, N B, some two years ago, but since then I have taken it plentifully in Carlisle, Morecambe, and Tunbridge Wells, besides receiving it from Sussex, Devonshire, Gloucestershire, Northants, and elsewhere It bears spermatophores during the spring months

When I was in the south of England in the early months of this year, I discovered a couple of specimens of a new British tree worm (*A constricta*, Rosa) This species seems to me to belong to the south, just as *D Boeckii* belongs to the north I am making notes on the distribution of these species in order if possible to ascertain their limits A very anomalous worm (*Lumbricus Eiseni*, Levinsen) belongs to this group, though it has certain Lumbricus affinities It is far from being a true Lumbricus, since it possesses neither *tubercula pubertatis* nor spermatheca Its girdle, too, is abnormal, for, whereas in the genuine Lumbricus the girdle invariably covers six segments, in this worm it extends over eight or nine At present it does not fit in to any known genus, and should probably be made the type of a new genus I have found it in Carlisle, Gloucestershire, and Sussex Rosa has obtained it in Italy, and Levinsen in Copenhagen, so that it appears to be very widely distributed On the Continent one or two further species belonging to this group are on record On account of their habits, size, and affinities I place them in the subgenus Dendrobæna, which may be presented in tabular form as follows —

Tabular View of Subgenus Dendrobæna

Dendrobæna	Segments occupied by the Girdle	Tubercula	First dorsal pore	Setæ	Prostomium	Colour
Boeckii, Eisen	29—33	31 32 33	—	8 equidistant	Cuts ⅔ peristomium	Dark brown
Subrubicunda, Eis	26—31	28 29 30	[illegible]	4 wide pairs	Cuts one half	Rose red, fleshy
Arborea, Eisen	27—31	29 30	[illegible]	4 wide pairs	Cuts one half	Red brown, iridescent
Eiseni Levinsen	24—32	0	[illegible]	4 close pairs	Cuts the whole	Violaceous iridescent
Constricta, Rosa	26—31	0	[illegible]	4 pairs	Cuts one half	Rose red, fleshy
Celtica, Rosa	30—36	33 34	—	4 wide pairs	Cuts one half	Violaceous, ruddy

Another group of worms belonging to the genus Allolobophora, with features more or less similar to those of the typical earthworm, has recently been enlarged by the addition of two or three species The first (*A profuga*, Rosa) seems to be generally distributed throughout England, as I have received it from several localities Its synonymy, however, is at present somewhat uncertain The long worm (*A longa*, Ude) is the most ubiquitous of all our native species, and has for years past been confused with the common earthworm. The other species must for the present be entered as *A. complanata* (Dugès) The Continental authorities differ in their judgment respecting the identity and synonymy of this worm, and I have hitherto been unable to disentangle the complications Certain it is that we have a species which corresponds in part with the worm described imperfectly by Dugès, and I hope in a little time to be able to determine its exact relationships

I append a list of all those species of British earthworms which I have personally collected, examined, and identified, in

each instance referring to the original memoir, and collating the worm with the author's description

When Darwin wrote his work on "Vegetable Mould," he assumed the existence of eight or ten species of earthworm in Great Britain We now find a score of well defined species, to which I have no doubt we shall be able to add a few others when the montane and out-of-the way habitats have been explored I shall be happy to receive consignments of living worms from any part of the kingdom, packed in tin boxes lightly filled with soft moss, and addressed The Grove, Idle, Bradford

HILDERIC FRIEND

THE PROBLEM OF MARINE BIOLOGY[1]

IN common with the other branches of biological science, the study of marine life has made wonderful advances in the past half century, and we now begin to get a proper conception of the vastness and importance of this realm of nature

The study of marine life has been compassed by serious difficulties, on shipboard it is impossible to examine in the living condition the enormous quantity and endless variety of forms brought up at a single haul of the net or dredge, and the old method of merely dropping the specimens into vials of alcohol resulted in vials of wrath to the naturalist who later studied the creatures in hopes of gaining from the distorted relics some knowledge of the normal appearance and anatomy Now all this is changed, and by aid of certain chemical reagents most animals can be killed and preserved in a manner very satisfactory for study of their gross and microscopical anatomy, and hence the material collected can be examined at leisure in permanent laboratories with results corresponding to the better facilities There has, too, been a great lack of suitable and accurate collecting apparatus The early method was to scoop up a quantity of sea water and then tediously examine it in small quantities under the microscope In 1845 Johannes Muller, the great pioneer of marine biology, conceived the idea of condensing into a small volume of water the forms which would be found in a very great area. This resulted in the invention of the "Muller Net," a small gauze net which is drawn through the water, entangling in its meshes the very minute and delicate organisms For a long time Muller and his students pursued the study of marine forms, and at length came the discovery that the marine fauna and flora was directly comparable to the terrestrial

Yet little is known of the laws of the distribution of marine life The laws of the distribution of the terrestrial fauna and flora have been formulated for animals in the classical works of Wallace and for plants by Griesbach The famous *Challenger* expedition (1873 1876), under the direction of Sir Wyville Thompson and Dr John Murray, has given us the largest conception of the wealth of marine life, and has laid the foundations for the study of the marine forms both at the surface and in the depths of the ocean Dr Murray in his preliminary report called particular attention to the enormous wealth of organic life not only at the surface, but also many hundred fathoms below He says that when living forms were scarce on the surface the tow net usually disclosed very numerous forms below, even to a depth of 1000 fathoms or more In the North Pacific Ocean, the discovery was made that zones of definite depth are characterized by animals and plants peculiar to them The tow nets sunk to 500, 1000, or 2000 fathoms brought up forms never found within 100 fathoms of the surface The animals characteristic of these different depths are, for the most part, of the class of Radiolarians, those microscopic organisms whose silicous skeletons form much of the soft ooze which carpets the bottom of the deep sea Prof Haeckel, by study of this material, was led, in his monumental work on the Radiolaria, which forms a part of the "Report of the Challenger," to the recognition of three groups, (*a*) pelagic, swimming at the surface of the calm sea, (*b*) zonary, swimming in definite zones of depth (to a depth of more than 20,000 feet), (*c*) profound (or abyssal) animals swimming immediately over the bottom of the deep sea In general the different characteristic forms correspond to the different zones (up to 27,000 feet)

The existence of this intermediate pelagic fauna was called in question by Alexander Agassiz, on the ground of the liability of error in using the ordinary open net instead of one which could be closed at a definite depth and then drawn up, and more particularly upon the ground of his own experiments made in 1878 on the *Blake* expedition He believes that the great bulk of the ocean contains no organic life at all, that the surface fauna of the sea is limited to a relatively thin layer, and that there is no intermediate layer, so to speak, of animal life between the fauna of the bottom of the deep sea and of the surface

Agassiz's results are contradicted by those of Chierchia on the Italian corvette *Vettor Pisani* With the closable net invented by Palumbo he brought up an astonishing quantity and variety of forms of life from different depths, even up to 4000 metres Prof Carl Chun, with an improved closable net, studied the marine fauna and flora of the Gulf of Naples He formulates his results as follows (1) That part of the Mediterranean investigated shows a rich pelagic life even to a depth of 1400 metres, as well as at the surface (2) Pelagic animals, which during the winter and spring appear at the surface, at the beginning of summer seek the depths (3) At greater depths pelagic animals occur, which hitherto have seldom or not at all been observed at the surface (4) A number of pelagic animals during the summer remain at the surface and never go into the depths From his observations upon the vertical distribution of marine life he was led to remark that the surface fauna was apparently only the advance guard of the vast army below His conclusions were confirmed by observations made during a trip to the Canary Islands, and agree with those made by Prof Haeckel twenty years before

Prof Hensen, of Kiel, has for several years past been studying the phenomena of pelagic life with a view of ascertaining its relations to the fisheries question He has proposed the term Plankton (from πλάνομαι, to wander) to designate this world of marine life Prof Haeckel agrees with this and adds Planktology, that branch of biology which deals with the study of the Plankton Prof Hensen hopes to gain valuable information upon the phenomena of marine life by a careful mathematical estimation of the number of individuals in a given bulk of water Presumably from this and other data some knowledge may be gained of the quantity of life which any definite area of the sea is capable of sustaining

Prof Ernst Haeckel, of Jena, has lately published an admirable *résumé* of our knowledge of pelagic life, and has made a very distinct advance by formulating some of the laws which govern its distribution He has probably done more than any

[1] Reprinted from the *American Naturalist* for October, 1892

one man to advance our knowledge on this line. Ever since 1854, when, as he tells us, he accompanied the great Johannes Müller to Heligoland and was there introduced by his master to the marine wonderland, he has almost continuously pursued the study of the Plankton. He believes that aquatic life in its broadest features shows conditions of distribution similar to those of terrestrial life, and that we may for the former as well as for the latter distinguish five great geographical provinces, each represented by characteristic forms of animals and plants: (1) the Arctic Ocean; (2) the Atlantic; (3) the Indian; (4) the Pacific; (5) the Antarctic.

All aquatic organic forms fall into two great divisions: (1) Those which live free in the water, either swimming actively or passively floating at the mercy of currents and winds. These compose the Plankton. The Plankton thus includes the widest range of organic size and form, from the minutest microscopic organisms to the gigantic cetaceans. (2) Those forms which live upon the sea bottom, either fixed or creeping about. To these the term Benthos (τὸ βένθος, the bottom of the ocean) is applied. The variety of forms living near the shore is known to vary with the depth, while the forms characteristic of the comparatively shallow waters of the coasts are widely different from those which inhabit the bottom of the deep sea.

The number and the kind of forms composing the Plankton are found to differ with the quality of the water, *i.e.* fresh or salt. In the ocean there is a marked difference which is conditioned by the distance from the shores, either of continents or islands. There are many species of animals, particularly certain cœlenterates, echinoderms, and worms, which pass only part of their life as free swimming animals; for the remainder, they are bottom dwellers. Such species are not usually found far from the coast, and hence the true oceanic Plankton is made up of forms which pass their entire life as free swimming organisms. By the presence or absence of these bottom dwelling species the Planktologist can determine approximately the region where the forms were captured.

A mere list of the genera, not to mention the species, of plants and animals up to the present found to take part in the constitution of the Plankton would be very formidable. The range in size is enormous; from the exceedingly minute unicellular algæ $\frac{1}{2500}$ of an inch in diameter to the huge bulk of many fishes and cetaceans. The microscopic forms constitute the fundamental food supply in the cycle of marine life. They are capable of exceedingly rapid multiplication, and furnish nourishment for the myriads of large animals, which in time are preyed upon by the still higher forms. The inconceivable number of individuals of the smaller species is demonstrated by Prof. Hensen's determination of the number of individuals in about two cubic yards of Baltic Sea water. This was found to contain 5,700,000 distinct organisms, of these only about 150,000 were visible to the unaided eye. But very often microscopic forms become so numerous as to form a slime upon the surface of the water for a considerable area. Ships frequently sail for miles through water coloured by these microscopic organisms, *e.g.*, the so called "black water" of the Arctic and Antarctic Seas, is a slime of diatoms, which serve as food for the shoals of minute crustacea and mollusca (Pteropods, sea butterflies, and Cephalopods, squid, cuttlefish) upon which the walrus and whales feed. In the warm regions the inconceivably enormous quantity of diatoms are replaced by another kind of alga, the Oscillatoriæ, which often for an area many miles in extent colour the sea a dark red or yellowish brown. The Red Sea received its name from the abundance of one of these algæ, *Trichodesmium erythræum*, which, according to Ehrenberg, coloured the water along the shore a blood-red. In the warm region also are found the huge floating banks of Sargassum, or gulfweed, forming the so called Sargasso Seas of the Atlantic and Pacific Oceans. These areas are found to have a marine fauna and flora peculiar to themselves, but approximating in character to that of the coast waters.

The simplest forms of animal life of the Plankton belong to the groups of Infusoria and Rhizopods; to the latter belong those minute animals, the Foraminifera and Radiolarians, which occur in such enormous quantities that their calcareous and siliceous shells form the "deep sea ooze" which carpets the bottom of the deep sea. It is the shells of these animals, too, which have built the vast chalk beds in various parts of the world. Among the multicellular animals which take a prominent part in this marine world are many species of medusæ (jelly fish) and the closely related Siphonophores, of which the beautiful Portuguese man-o'-war is the most familiar representative. The class of worms is represented by many free-swimming species; but in the number of individuals it is far surpassed by the molluscs, chiefly represented by the squids, the pearly and paper nautilus, and the huge cuttlefish, and by the minute and delicately beautiful sea butterflies (Pteropods), which occur in vast schools in the polar seas. Often, too, in very considerable number are found the free-swimming larvæ of Echinoderms, as also many worm larvæ, which, like the former, pass their adult life upon the bottom. Every haul of the gauze net is certain to contain some representatives of the great class of Crustacea, often great numbers of species, as well as of individuals. In distribution these seem to be subject to pretty definite laws, and a careful study of the phenomena would be of great interest. There are found also certain Tunicates, a group interesting because many investigators believe that here we find the transition from the invertebrate ancestor to the higher plane of life of which man is at present the highest representative.

The vertebrates of the Plankton embrace the great group of fishes, and in addition the marine birds, the seals and walrus, and finally the cetaceans. In this connection, too, the enormous number of fish eggs floating at the surface of the ocean, as well as the transparent, newly-hatched fry must be mentioned. Prof. Hensen hopes to get an idea of the approximate number of fish of a given species in a certain area, computing the number of eggs and fry of that species within that area.

The phenomenon of marine phosphorescence is very widely known with admiration and wonder. Its cause is chiefly or solely bound up with organic life. The majority of pelagic animals display the phosphorescent light in different degrees. In some the entire living animal is brightly luminous; in other the light is limited to special organs. But much of the phosphorescence of the ocean appears to be caused by the fragments of dead organisms, and is connected with the presence of bacteria.

Since many chlorophyll bearing organisms are found at depths unpenetrated by sunlight, it has been suggested that the light necessary for their growth is furnished by the phosphorescent organisms.

The composition of the Plankton is exceedingly irregular, both in qualitative and in quantitative relations; its distribution in the ocean is also very irregular, both in time and in place. The variations occur near the shore as well as far out at sea. Very often the greater part of the mass of Plankton is made up of organisms belonging to a single group. Sometimes unicellular algæ make up nearly the whole bulk, at another medusæ, siphonophores or ctenophores; indeed, almost any group of marine organisms may occur in such quantities as to compose more than one half of the total bulk of the Plankton, at that time and place. The fundamental causes of variation in the quantity and quality of the Plankton appears to be conditioned by time, climate, and currents.

Temporal Differences.—For a satisfactory determination of these more complete observations are needed. Reliable data can be furnished by the observations at the numerous marine laboratories and zoological stations now springing up in different parts of the world. The causes which underlie these yearly, monthly, daily, and hourly variations are manifold; in part meteorological, in part biological. They are comparable to the corresponding oscillations of the terrestrial fauna and flora, and depend on the one side upon climatic and meteorological conditions, and on the other upon the varying mode of life, particularly upon conditions of reproduction and development. Just as the annual development of most land plants is bound up with a definite time of year, as the time of budding and leafing, of blooming and fruiting, have in the "struggle for existence" become adapted to the meteorological conditions, the time of year, and other conditions of existence, so too the annual development of most marine animals is conditioned by definite habits, which have become fixed by heredity. The yearly variations may be compared to the good and bad fruit years. This yearly variation has been noted by many observers in case of many marine animals. Our attention is often called to an example of it in the unusual abundance or scarcity of the catch of certain food fishes.

Many marine animals, particularly certain medusæ, siphonophores, ctenophores, molluscs, and tunicates, are found at the

surface only periodically, in one or a few months of the year This is probably dependent upon conditions of reproduction and development, as well as upon the temperature of the season The daily variations are conditioned by the weather, and particularly by the wind and rain A shower will very quickly reduce the specific gravity of the surface water and thus drive the surface-dwelling animals below Many animals rise to the surface only at a definite time of day, some in the morning, others at noon, and yet others only towards evening

Climatic Difference —Prof Haeckel thinks that the quantity of the Plankton is very little dependent upon the climatic difference of the zones, but that the quality is greatly so, and indeed in this way, that the number of component species diminishes from the equator to the poles These conditions, he believes, are directly referable to the influence of the sun, "the omnipotent creator," whose more direct rays bring about an acceleration in the processes which make up the cycle of life As this is true of the terrestrial fauna and flora so it is true of the marine

Currentic Differences —Conspicuous differences are also brought about by the numberless currents, great and small, by the little known deep sea oceanic currents as well as by the better known great surface currents, the Gulf Stream, the Falkland Stream, the Guinea Stream and others These currents play a great *rôle* in the distribution of many forms of life More local influences are exerted by the small currents whose causes are found in the climatic and geographical conditions of the adjacent coast The relations of Plankton life to currents is little known, and needs investigation, but first a better knowledge of the currents themselves is necessary

Almost every one who has seen the surface of the ocean in a calm has noticed the glassy areas of irregular shape These are found on the high seas as well as in sheltered bays and harbours, and are of very special interest to the student of marine life So far as made out they are extremely irregular in time and place of appearance, and the conditions governing them have not been carefully studied They are in a measure influenced by winds and currents, by the ebb and flow of the tide Here, into a limited space, are crowded great numbers of organic forms, this space is readily distinguished from the surrounding water in which there is comparatively little life These phenomena have been noticed by seafaring men and have many different names in different countries

A word in conclusion as to the bearing and importance of the Plankton in human economy in the near future When Malthus promulgated his famous doctrine he failed to consider the final element which enters into the problem of human population, the human mind The ingenuity of the human mind has brought about a decreased efficiency in the natural checks to undue increase, and thus an artificial increase in the food supply is rendered necessary for the crowding population This food supply is now mainly derived from the cultivation of the land A still further increase of population will necessitate a levy upon marine life As soon as man to any great degree becomes a factor in the Plankton conditions by drawing from it large quantities of food, particularly in the form of mature animals, the equilibrium of oceanic life will be disturbed, and must be adjusted by artificial means But further, a study of the phenomena of marine life shows that the water as well as the land, through cultivation, is capable of producing a greatly increased food supply for man The necessity of cultivating the marine resources is even now apparent, and many governments have already begun to cope with the question by the establishment of commissions of fisheries Of these commissions that of the United States stands in the front rank by virtue of its positive results But in the near future individual attention must be turned to supplementing the terrestrial resources, the wheat fields, the cattle and sheep ranches, by an increasing utilization and development of the possibilities of marine farming, by fish propagation, by plantations of oysters, clams, quahaugs and scallops, by raising herds of lobsters and crabs Improved breed of fish, of lobsters will result The possibilities are well-nigh limitless, and by cultivation of the sea and sea bottom, as well as of the land, man will postpone indefinitely the fulfilment of the Malthusian prophecy.

But conditioning all advance in the possibilities of marine cultivation is the knowledge of the Plankton, of its distribution, and of the fundamental basis of marine life the microscopic marine organisms in the ocean.

GEORGE W. FIELD

OPTICAL PROJECTION[1]

THE intention of this lecture is to give a general survey of the subject of Optical Projection, which now takes its position in science, and to present examples of what may be done by this method It would be difficult to determine which subject claims a first place Some scientists say the microscope should have the preference, while others take a different view For my own part, I think the microscope and polariscope stand foremost, on account of the facility with which these branches of science may be pursued for the benefit of a large number, without multiplying expensive apparatus, also because of the convenience in saving the eyes from undue strain Indeed, to many persons, looking at objects in the table microscope is little short of a painful operation, and consequently the study of small objects becomes to them impossible The projection method immediately brings the required relief

For general instruction, projection methods are invaluable, such as, for instance, showing diagrams, photographs, and other slides, upon the screen, as well as for spectrum analysis In fact, the subjects which can be illustrated by means of optical projection are innumerable, but time will allow me to present only a few examples, and I trust that, when I approach the end of my lecture, my view of the importance of this subject will be held in equal estimation by you

Probably the only people in the world that benefit by the experience of their predecessors are those who pursue the study of science They are free from the accusation of robbing the brains of other men, when they take up methods or apparatus already known and improve upon them or employ them for their own work In such cases, however, it is always understood that honour should be given where honour is due, and accordingly I have no wish to represent to you any piece of apparatus as of my own devising, when in reality it belongs to another

Few men have had a larger experience, and attained greater success in optical projection, than has Mr Lewis Wright, who has embodied in his most recent forms of apparatus all that was good in designs existing until his time I have, therefore, started from his models making such modifications as I thought to be desirable Mr Wright does not appear—if I may say so—to have had much experience with the electric arc light as a radiant, and I found, at a very early stage, that great difficulties had to be encountered when this light was used, chiefly because the radiant approaches more nearly to what theory requires That which was easy with the lime-light became almost impossible with the arc lamp, and these difficulties had to be conquered

Many scientific men are dissatisfied with the projection microscope, on the ground that very high magnification does not give that resolution and that sharpness which is found in the usual methods of observation This want I fully admit At the same time it is scarcely right to condemn a particular method because you try to apply it to an unsuitable purpose Hundreds of thousands of subjects may be shown with the projection microscope with far greater profit to the student than was possible in the old way The very fact that the professor can place his pointer upon any part of the picture on the screen is invaluable to the students I shall, therefore, attempt to show you only a series of microscopical subjects suitable for projection, and shall not employ very high magnification

In regard to some substances very high powers may be used with advantage, but much time would be lost in getting them into the field and focussing them upon the screen These, consequently, I omit, so that a large number of subjects may be illustrated

It is fair to state that most of the apparatus used to-night has been constructed by Messrs Newton, of Fleet street, and the luminous pointer by Messrs Steward, of the Strand The arc lamp is a Brockie's projector Messrs Baker, Watson, and others have also come to my assistance

I will first show, on the screen, a picture of the lantern carrying its various apparatus, and then a few systems of lenses, which may be employed for the projection microscope, as well as a diagram of the microscope itself

Sub-stage condensers and objectives are, as a rule, made to suit the table microscope When projecting, by means of an objective alone, in consequence of the screen distance being very

[1] Friday evening discourse delivered by Sir David Salomons at the Royal Institution, on February 26.

great—or, in other words, the microscope tube being exceedingly long as compared with the table instrument—the objective has to be approached very close to the slide, in fact, with the higher powers, closer than the cover-glass will allow. This close working distance renders necessary special sub-stage condensers, and in many cases a special one is required for every screen distance with each objective. This requisite would seem to be a complete stumbling block to microscope projection work. With the lime light the difficulty does not enter in the same degree as with the arc light, and as we are now dealing with the latter, further reference need not be made to the oxy-hydrogen light. There are two ways of surmounting the difficulty, one by the use of plano concave lenses, introduced in such a way as to be equivalent to greatly lengthening the focus of the objective on the screen side, while it enables, as a consequence, the objective to be slightly further removed from the slide, *i.e.*, giving what is termed a greater working distance. The objection to this method is that, even when these plano-concave lenses are corrected, the result, though greatly improved, is not perfect. The second way, which is a perfect one, is that of introducing an eye-piece. In both these methods, that the best results may be obtained, the objective is made to occupy a position not very different from that which it would do if employed on the table microscope.

In the eye-piece method almost the exact conditions can be complied with for which the objective was made. I propose, therefore, to show the subjects by the eye-piece method. The only objectives which will be used are (1) Zeiss's 35 millimetre projection objective, with a sub stage condenser, 4 inches focal length placed a considerable distance from the slide, (2) Newton's 1 inch projection objective, the sub-stage condenser as in the first case, and (3) Zeiss's $\frac{1}{4}$ inch achromatic objective, the sub stage condenser being Prof. Abbe's three-lens condenser with the front lens removed. In all three cases the eye pieces used are Zeiss Huyghens No. 2 and No. 3.

In each instance I will mention the magnification in diameters, as well as the number of times when reckoned by area, for the appreciation of those who estimate by area, and I will also give the size to which a penny postage stamp would be increased, supposing it to be made of india rubber, and stretchable to any extent in all directions. In presenting these figures I do not pretend that they are absolutely correct, but as they have been ascertained under conditions similar to those now existing the errors will not be very great.

In consequence of the field not being quite flat, and the sections having a certain thickness, although extremely thin in most cases, the whole of the object cannot be in focus upon the screen at the same time. By shifting the focussing screw slightly all parts may be brought into focus successively. So called greater depth of focus is obtained by using an increased working distance, and for projection work over correction for flatness can alone give a sharp picture all over with very considerable depth of focus, the difficulty of over-correction being that, unless extreme care is taken, certain forms of distortion may be introduced. By stopping down the objective greater flatness of field may be secured, but at the expense of light. There is thus a choice of difficulties, and the least one should be taken.

Turning now to the polariscope. Polarized light teaches us a great deal concerning the structure of matter, it is also a means of confirming the undulatory theory of light. This subject is so large that no attempt can be made to give even a general idea of the field it covers, and the experiments, which will be shown in the polariscope, may be taken simply as a few illustrations of the subject and nothing more, but they will, at any rate, be suggestive of the large field to which this method of analysis can be applied. A vast amount of mathematical proof can be illustrated graphically by various experiments with polarized light. I will show on the screen a diagram of the polariscope. (Shown.)

With reference to showing the spectrum. The method of projecting a spectrum, I think, is new, as I have not seen it described anywhere. It gives practically a direct spectrum with an ordinary prism, without turning the lantern round to an angle with the screen, and here is a diagram of the method.

The details of the apparatus, as well as those of the methods of working, I have modified in almost every instance, for five reasons:—(1) That more certain results may be ensured, (2) that rapidity may be obtained; (3) that only one operator may be needed, (4) that, as far as possible, all parts of the apparatus may be interchangeable; and (5) that loose screws and pieces may be dispensed with.

There were then shown by projection a number of slides illustrating various microscopic optical systems, and a number of microscopic slides, followed by a series of general polariscopic projections, some of them to illustrate the strains existing in many forms of matter, also a spectrum by a carbon disulphide prism, in conjunction with a reflecting prism and with a mirror, which, apart from any other result, demonstrates that the loss of light with a reflecting prism is less than with an ordinary glass mirror. Slides and other projections were also thrown upon the screen.

The details are as follows:—

The Microscope.—Screen distance, 21 feet. First, 35 millimetres Zeiss projection objective, 4 inch sub-stage condenser, Zeiss Huyghens eye piece 2, 500 diameters = 250,000 times = penny stamp stretched to cover about 147 square yards. Subjects shown: proboscis of blowfly, permanent molar displacing milk-tooth (kitten), human scalp, vertical, human scalp, surface, fossil ammonites and belemnite. Second, 1 inch Newton's projection objective, 4 inch sub-stage condenser, Zeiss Huyghen's eye-piece 2. 1,000 diameters = 1,000,000 times = stamp stretched to about 588 square yards. Objects shown: proboscis of blow-fly, foot of a caterpillar, section of human skin, showing the sweat ducts, phylloxera vastatrix of the vine. Third, 1-inch Newton's projection objective, 4-inch sub stage condenser, Zeiss Huyghens eye-piece 3, 1,300 diameters = 1,690,000 times = stamp stretched to about one fifth of an acre. Slides shown: proboscis of blow-fly, wings of bee (showing hooklets and ridge), sting of bee (showing the two stings, sheath, and poison sack), sting of wasp (showing same as last slide), eye of beetle (showing the facets). Fourth, $\frac{1}{4}$ inch Zeiss's achromatic objective. Abbé's 3-lens sub stage condenser, with top lens removed, Zeiss Huyghens eye piece 3, 4,500 diameters = 20,250,000 times = stamp extended to nearly $2\frac{1}{2}$ acres. Slides shown: proboscis of blow fly, hair of reindeer (showing cell structure), hair of Indian bat (showing the peculiar funnel-like structure), sting of bee (showing the barbs), foot of spider, stage of the micrometer (the closest lines ruled to thousandth of an inch, which measure $4\frac{1}{2}$ inches apart under this magnification), a wave length $\frac{1}{40000}$ inch, therefore, on screen measures about $\frac{1}{9}$ inch.

The Polariscope.—Shown with parallel light: plain glass, glass under pressure, chilled glass (round, oval, and waved peripheries), Prince Rupert's drop (broken in the field), horn, selenites (over-lapped), butterfly (selenite), bunch of grapes (selenite), bi-quartz, with $\frac{1}{4}$-wave plate (the $\frac{1}{4}$ wave plate in this experiment produces the same effect upon the bi-quartz as if a column, 20 centimetres long, of a $7\frac{1}{2}$ per cent. solution of cane sugar were placed between the polarizing nicol and the bi-quartz. The analyser has to be rotated about 10°), a piece of sapphire to show asterism. Shown with convergent light, hemitrope (cut in a plane, not at right angles to the axis), ruby, topaz, grape sugar (diabetic), cane sugar, quartz, superposed right and left-handed quartz (spirals), calcite and phosphate superposed (showing transition from negative to positive ... passing through the apophyllite stage).

The Solidiscope.—New form of apparatus for showing solids, and consisting of two reflecting prisms and suitable projecting lenses. With this instrument were shown:—Barton's button, the works of a watch, a coin.

Spectrum Analysis.—Spectrum thrown by means of a disulphide prism combined with a reflecting prism, the result being that a good spectrum is thrown upon the screen direct without turning the lantern. There were shown:—The spectrum, absorption bands of chlorophyll, &c., effects produced by passing the light through coloured gelatine films.

Projection of Slides.—Decomposition of water; expansion of a wire by means of heat, combination of colours to form white light, various diagrams, coloured photographs of a workshop, &c. As an extra experiment there was shown, in the polariscope, with a convergent light, Mitscherlisch's experiment (illustrating the changes which take place in a selenite under the influence of heat).

There are but few who would disagree with me in the opinion that the microscopic world, as regards its design and its molecular structure, is quite as wonderful as the great works around us seen with the unaided eye. A magnifying glass of low power opens up a world far larger than that which we are accustomed to see. At the present time, even with the most perfect apparatus that exist, only a small portion of the universe is known to us.

Scientific study should be pursued by all in a greater or less degree It teaches more important lessons than the most impressive discourse ever preached During the investigation of what is generally termed the invisible world, men should at time pause to reflect, and ask themselves such questions as these What is the meaning of, and to what end is, creation? Is it all mere chance? Were such wonderful designs and properties created at the beginning? Was there in matter at the beginning an inherent, or implanted, power of development? Simple as these questions may seem, man in the flesh will never be able to find the true answers The extraordinary design and structure which have existed in the unseen world for millions of years, or possibly in all past time, and even at the present day known to so few, demonstrate at least that the great Power has bestowed the same care upon what appear to us the most insignificant portions of creation, as upon what we think are the greatest works in the universe. These silent sermons must surely influence the mind, and set it thinking of the supernatural and of our duties during life

It may now with truth be said that science gives us means, such as never before existed, of appreciating the greatness of the Supreme Spirit, by enabling us to read fresh chapters in the book of nature

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —Prof Darwin has been appointed to represent the University at the approaching tercentenary of Galileo's appointment to a chair in the University of Padua The celebration will take place in Padua at the beginning of December

Prof Green, of Oxford, is appointed an Elector to the Harkness University Scholarship in Geology in the place of the late Mr T Roberts, assistant to the Woodwardian Professor

The discussion in the Senate of the proposal to found a mechanical sciences tripos for engineering students was unexpectedly favourable, in marked contrast to the reception accorded to former schemes Prof Ewing is to be congratulated on the skill with which the new plan has been framed, and the success with which he has met and conciliated the original opposition of the more mathematical members of the Senate The grants for the approval of the plan have been sanctioned by the Council, and it is not likely that they will now be opposed Some fifteen students are already at work in the engineering laboratory in preparation for the new tripos, which bids fair to take a good place among the honours schools, and cannot fail to stimulate the growth of the engineering department under its present energetic head

DUBLIN —At the meeting of Council of the Royal College of Science, Dublin, held on the 5th inst , a letter was read from H M Commissioners for the Exhibition of 1851, announcing that they had been pleased to place at the disposal of the College a science scholarship of the annual value of £150 for the year 1893. These scholarships are specially instituted for the encouragement of scientific research and are tenable for two years, and one of them has already been nominated to by the Council of the College for the year 1891 92

SCIENTIFIC SERIALS

American Journal of Science, October —On a colour system, by O N Rood —An ottrelite-bearing phase of a metamorphic conglomerate in the Green Mountains, by C L Whittle —The age coating in incandescent lamps, by E L Nichols The diminution of efficiency in incandescent lamps is due to three causes, viz , loss of vacuum, increase of resistance due to the the disintegration of the filament, and finally the deposition of disintegrated carbon upon the inner surface of the lamp-bulb This deposition gives rise to what is called the age-coating It appears that the rate of deposit of the coating in incandescent lamp-bulbs is greatest in the early part of the life of the lamp For example, in the case of a lamp which lasted 800 hours, more than half the coating was deposited during the first 200 hours The loss of brightness due to the absorbing power of the age-coating is a variable part of the total loss, being greatest in lamps of high initial efficiency The coating does not appreciably modify the character of the light transmitted, as shown by a series of photo-spectroscopic measurements The distribution of the coating within the bulb is nearly uniform. No marked difference between treated and untreated filaments appears to exist as regards the coating produced from them It has been pointed out, however, that in the case of lamps exhausted without the aid of mercury the age-coating is scarcely perceptible —Mica-peridotite from Kentucky, by J S Diller —Glaciation in the Finger Lake region of New York, by D F Lincoln —Certain points in the interaction of potassium permanganate and sulphuric acid, by F A Gooch and E W Danner When these two bodies are brought into solution together there is developed a tendency towards reduction on the part of the permanganate, which is the greater as the strength of the acid is increased, as the temperature is raised, and as the duration of the action is extended At first, the oxygen lost to the permanganate is liberated, whereas in the later stages manganese is precipitated in the form of a higher oxide or retained in solution in the form of a higher sulphate —Crystallography of the cæsium mercuric halides, by S L Penfield —Silver hemisulphate, by M C Lea —Restorations of Claosaurus and Ceratosaurus, by O C Marsh —Restoration of *Mastodon Americanus* (Cuvier), by the same

THE number of the *Nuovo Giornale Botanico Italiano* for October is entirely occupied by the continuation of Sig Nicotia's Statistics of the Flora of Sicily

American Journal of Mathematics, vol xiv , No 3 (Baltimore, the John Hopkins Press, 1892) —The title of Prof Cayley's communication, "Corrected Seminoniant tables for the Weights 11 and 12" (pp 195-200) explains itself It contains a better form of tables, which were given in a previous volume (vii , pp 59-73) Weierstrass, in his memoir "Zur Funktionenlehre," called attention to certain functions, which offer special singularities "Au lieu de présenter un nombre fini ou infini de points singuliers essentiels *isolés* elles offrent des lignes singulières essentielles ou même des *espaces lacunaires* à l'intérieur desquels elles cessent d'exister "— By request of Mr Hermit, M H Poincaré discusses the subject in an article "Sur les fonctions à espaces lacunaires " (pp 201 221) —J C Field, writes on "Transformation of a System of Independent Variables" (pp 230-236) —Mansfield Merriman discusses "The deduction of final formulas for the Algebraic Solution of the Quartic Equation" (pp 237-245), and I S Hulburt in remarks on "A class of new theorems on the number and arrangement of the real branches of plane Algebraic Curves" (pp 246-250), follows up recent work, in the same direction, by Messrs Harnack and Hilbert "—"The Symbolic notation of Aronhold and Clebsch" (pp 251-261) has for its object the exposition of this notation, "so well adapted to the expression of functional invariants," in an English form The same writer, W F Osgood, also contributes a note on "the System of two simultaneous Ternary Quadratic forms" (pp 262-273) This, likewise, is a simplification for the benefit of English readers It contains an account of Gordon's method, and employs the notation of the preceding article —H S White communicates notes "on generating systems of Ternary and Quaternary Linear transformations" (pp 274-282), and "a Symbolic demonstration of Hilbert's method for deriving Invariants and Covariants of given Ternary forms" (pp 283-290) This latter paper also uses the symbolic notation of Aronhold and Clebsch in a simplified statement of recent results developed in Hilbert's notable paper "Ueber die Theorie der Algebraischen Formen" (Math - Aca , vol 36, pp 524-6). The only paper, in the present number, which was read before the New York Mathematical Society is one by the President, Emory McClintock, "On the Computation of Covariants by Transvection" (pp 222-229)

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, October 17 —M Duchartre in the chair —On Mr Barnard's discovery of the fifth satellite of Jupiter, by M F Tisserand —On the application of certain methods of successive approximation to ordinary differential equations, by M Emile Picard — On a reaction alleged to be peculiar to spermine, by M Duclaux.—Observations of three new small planets discovered at the Nice observatory by means of photography, by M Charlois ; report by M Perrotin (see Astronomical Column) —On the coexistence of dielectric power and electrolytic conductivity, by M E Bouty A vindication of priority.—On the polarization of light of various colours by the atmosphere, by M N Piltschikoff There is a well marked difference between the intensity of polarization of blue light and that of red in the atmosphere The intensities are measured by

means of a Cornu photo polarimeter The eye-end of this instrument is covered with a cobalt glass, the quantity of polarized light from the chosen point in the sky is measured, the blue glass replaced by a ruby glass, and the determination repeated for the latter Generally, the intensity of polarization for blue light is sensibly greater than that of the red This is not favourable to Lallemand's theory of the blue colour of the sky as a phenomenon of fluorescence The difference of polarization is, however, not constant, but depends upon the direction of the wind A series of observations made at Kharkoff between April and September, 1892, show a maximum difference with a south easterly wind, diminishing symmetrically on both sides, and even becoming negative at W N W. The amount of polarization of the blue shows the opposite distribution, so that when the polarization of the atmosphere rises or falls, the effect is greater in the less refrangible radiations than in the others There is also a notable relation between polarization and atmospheric moisture The S.E brings the greatest amount of precipitation, the northerly winds the least It is also probable that dust and dry fogs exert a considerable influence, as shown by the circumstance that the greatest differences have been obtained in high winds, when the whole town was covered with dust -On a new way of preparing acetylene, by M I Maquenne (see Notes) —On the analysis of mixtures of ammonia and methylamines, by M H Quantin —On the nervous tissues of some invertebrates, by M. A B Griffiths —Examination of some rocks collected by Prince Henry of Orléans on the lower Black River in Tonkin, by M. Stanislas Meunier —Note on the miocene formations of western Algeria, by M Jules Welsch The miocene formations occur in normal succession near Hamman Riva, where they rest on the Cretaceous It appears certain that the last upheaval of the Atlas did not take place at the end of the Helvetian epoch (middle miocene), as hitherto believed It was post Tortonian, and took place at the end of the upper miocene For the formations of Gontas, Ben Chicao, Mascara, &c , are Tortonian , they are within the block of the Atlas Mountains, and have been lifted to heights of 800, 1000, and even 1700 metres This result tends to confirm the general idea worked out within the last few years that the zones of folding are nearer the equator in proportion as they are more recent

AMSTERDAM

Royal Academy of Sciences, September 24, Prof Van de Sande Bakhuysen in the chair —Mr H A Lorentz dealt with the reflection of light by moving bodies In a former paper ("Arch neerlandaises," t xxv p 363) the author considered the propagation of light through a ponderable dielectric which has a movement of translation, but leaves at rest the inclosed ether The equations then arrived at may be written in the form—

$$\operatorname{div} D = 0, \quad \operatorname{div} H = 0,$$

$$\operatorname{curl} E = -H, \operatorname{curl}\left[H + \frac{1}{v^2}\operatorname{vect}(Fp)\right] 4\pi D,$$

$$4\pi V^2 D = n^2 E + \operatorname{vect}(Hp),$$

the vectors H, D, E, and p representing the magnetic force, the dielectric displacement, the electric force, and the velocity of the ponderable matter The signs "div" and "curl" have the same meaning as in Heaviside's formulæ (*Phil Mag*, 5th ser vol xxii p 118), and Vect (Ep) indicates the vector product Finally, V is the velocity of light in vacuum, and n the index of refraction At the boundary of two media, possessing a common translation, there will be continuity of the normal components of D and H, and of the tangential components of E and $\left[H + \frac{1}{v^2}\operatorname{vect}(Ep)\right]$ If i and r are the angles of incidence and refraction for the relative rays ("Arch neerlandaises," t 21, pp 129–134), Fresnel's expressions for the amplitude of the reflected ray—

$$\frac{\sin(i-r)}{\sin(i+r)} \text{ and } \frac{tg(i-r)}{tg(i+r)}$$

have to be multiplied by

$$1 - \frac{2p_1 \cos i}{Vn_1},$$

where n_1 relates to the first medium, and p_1 is the velocity, in the direction of the normal, with which the reflecting surface recedes. This result may be shown to be consistent with the conservation of energy, provided that the pressure exerted, according to Maxwell, by the vibratory motion, be taken into account.—M van Bemmelen made a second communication on the existence of the crystalline hydrate of Fe_2O_3. He obtained the ferrite of sodium ($Fe_2O_3Na_2O$) in different crystal forms Under certain circumstances this form was a hexagonal plate These crystals could be metamorphosed by the action of water in the hydrate of Fe_2O_3, without loss of their optical properties

BOOKS, PAMPHLETS, and SERIALS RECEIVED

THE UNIVERSITY COMMISSION

THE University Commission is sitting frequently and has heard witnesses representing nearly every interest and every shade of opinion which have a right to be represented before it We have no knowledge of the effect which the evidence laid before them has produced upon the minds of the Commissioners, but we are sure that it must largely depend on the view which they have adopted as to the nature of their duties They may regard themselves as entrusted with the task of finding the terms on which a heterogeneous crowd of colleges and mechanics' institutes may be huddled together, called a university, and allowed to confer degrees on such conditions as the rivalries of competing institutions may permit when tempered by the moderating influence of Crown nominees, county councillors, representatives of the School Board and of the learned societies, and any other assessors whom fancy may suggest Such a solution might no doubt secure peace in the sense that, wearied out by long debate and hopeless of a satisfactory solution, those who are most nearly interested in the question might at last be compelled to make the best of a bad job

This, however, must be urged against it That almost every teacher of eminence in London, together with a large number of those best qualified to represent the educational views of the provinces, have declared *a priori* that it would be unsatisfactory

The other view which the Commissioners may take is that they are charged with the responsible task of defining the ideal system which would best provide for the supply of the higher education in London That having defined this ideal they are then to proceed to show by what means the closest approximation to it which present circumstances will allow can be made, and so to fashion the constitution of the University as to ensure in the future a closer approximation still That this is the wider and more statesmanlike view is beyond question, and we sincerely hope that the Commission will adopt it We may further hope that they will remember that although the new University should be able and willing to undertake all the multifarious duties which modern Universities have accepted as their own, the provision of the highest education and the doing all that in it lies for the advancement of learning must after all be the first and the highest duty of a University worthy of the name As to the means which would best realize these ideals there cannot be a doubt The present educational chaos must be reduced to order, the unwholesome rivalry between the London Colleges must be checked

On this point Prof Rucker, in an address recently delivered at the Yorkshire College in Leeds, made some remarks which we cannot do better than quote in full —

"The great provincial colleges are grouping themselves into greater Universities In the north Manchester, Liverpool, and Leeds have concluded a formal alliance. Negotiations are already in progress for the establishment of a similar confederation in Wales The Midlands will no doubt follow suit But if these afford, if in particular the north of England affords in the Victoria University, one of the happiest illustrations of the advantage of allowing free play to the tendencies which make for union no less than to those which encourage separation, we have, unfortunately, in London a striking instance of the harm which follows if the action of either the one or other is artificially restrained

"The northern colleges were indeed happy in that the tendency to union was called into play while they were still in a sufficiently early and plastic stage of their history to yield easily to its influence. In London difficulties, which seemed far more serious half a century ago than they do to most of us now, have unfortunately retarded all centralizing action, till the sentiment and traditions which accumulate round institutions that have long moved independently, have enormously increased the inertia which tends to keep them in their separate paths

"This is the more unfortunate, as if a new University of London is to be a really great teaching university, the relations between the London colleges must ultimately be closer than those which obtain between Manchester, Liverpool, and Leeds The principle of recognizing as colleges of the University institutions for the teaching and management of which the University is not responsible, has worked and is working admirably in the north of England It does not follow that it would succeed in London There

is indeed a fundamental difference between the two cases The colleges of the Victoria University are widely separated, and appeal to the strong local feeling of powerful and independent districts A generous rivalry may therefore exist between them without ill result. Each should be left, as they have been left, to work out their own success with as little external interference as possible.

"It is sometimes argued that because the population of London largely exceeds that even of such districts as Lancashire or the West Riding, there ought to be room within it for the separate and independent institutions in which teaching of the highest type could be provided This view ignores the importance of geographical separation, and unduly exalts that of the numerical magnitude of the population whose wants are to be met If Manchester and Leeds were on opposite sides of the Irwell or the Aire, if they were connected by an elaborate system of over-ground and underground railways, then it would be more economical to concentrate, in one or the other, the higher teaching which must now perforce be given in both The loss of time to the students in reaching the scene of their daily labours would be but imperceptibly increased, while the prestige of the colleges, great as it already is, their claims on the State, strong as they already are, would be enhanced in a proportion greater than that calculated by merely adding their separate reputations and resources In a city of the size of London it is desirable to multiply institutions in which preparatory work of all sorts is undertaken, but I think it may be assumed as almost axiomatic that it is impossible, at present at all events, to create in one town more than one institution in which laboratories and lecture rooms and the other machinery of scientific instruction shall be provided on the large scale which the elaboration of the highest modern scientific teaching demands In London, then, the teachers in almost all existing institutions feel the necessity for a combination of forces. They have expressed themselves as willing to be formed into battalions and regiments rather than to be left to carry on their work as isolated companies I will not dwell on the fact that this desire could only be declared by men who were willing to risk their personal position for the public good, but I want you to observe how in this case also the work of decentralization, which began with the foundation of University College, London, has been followed and would have been far more effective had it been accompanied by a corresponding manifestation of centralizing force"

With these views we heartily agree.

If ever we are to have in London laboratories such as those which are to be found in Germany, it can only be if the higher teaching in each subject is concentrated in some one great central institution, and if rival colleges are allowed to combine their forces for the public good, instead of being compelled as at present to fritter them in suicidal competition

Taking it for granted that all will admit that such an ideal would be the best if it could be realized, we believe that the possibility of its realization is chiefly doubted on two grounds, to neither of which any real importance is to be attached.

It has been supposed, in the first place, that those who advocate a policy of union among the London colleges think that this union must be carried out in all particulars immediately; and secondly that in order to secure this end it must be carried out by compulsion, even if the practical confiscation of the property of the existing colleges were necessary.

It need hardly be said that such a statement is a parody of the views of men who have had at least as much experience as their critics (of the tone of mind of the governing bodies of great educational institutions, and who therefore would be the first to anticipate the difficulties which such demands would inevitably cause

No responsible body has, as far as we are aware, advocated more than the establishment of a University on a basis which would permit the union of the various colleges, in whose buildings the University teaching might at first be carried on, if the colleges were themselves willing that such a union should be effected The advocates of union have all along been striving, not to attain an immediate and complete realization of their ideal University of London, but to prevent the Charter being drawn so as to make that realization impossible It cannot be beyond the limits of human skill to frame a scheme which shall offer every inducement to the London colleges to effect an immediate fusion, and shall further provide that any approximation which may at first take place shall easily become closer in the future.

The Victoria University does not consist of competing colleges A federal University of London would consist of colleges which from their mere local proximity would, whether they willed it or no, be necessarily antagonistic Unless the Commissioners fairly grasp this fact and realize that they have it in their power to lay down the lines on which a great institution shall be founded in close connection with the State, which shall concentrate under one central directing power all the educational efforts which are at present partly wasted through want of joint action, they will have failed to make the most of a great opportunity, and will have frittered the forces which, if allowed free play, are competent to do for the higher education of London all that the best friends of London can desire

THE STUDY OF ANIMAL LIFE

The Study of Animal Life By J Arthu Thomson, M A, F R S E "University Extension Manuals" (London Murray, 1892)

THE chief aim of an "Extension Manual" as of "Extension lectures" is to stimulate interest and to spread information In natural science, at any rate, it is impracticable through the medium of either Extension lectures or Extension manuals, to give that training which the student, be he specialist or generalist, can obtain only by practical work, aided by practical instruction But there are a great number of people, some already busily engaged, others on the threshold of their life's work, who possess some interest in, and some information about, those matters, with the study of which scientific men are occupied For them Extension lectures and manuals are a great boon, and to them Mr Thomson's work on "The Study of Animal Life" may be cordially recommended We trust it will stimulate them, as he would desire, to become themselves observers.

The work is divided into four parts, of which the first, entitled "The Everyday Life of Animals," deals with the wealth of life, the web of life, the struggle of life, the shifts for a living, the social life of animals, the domestic life of animals, and the industries of animals The second part, on "The Powers of Life," contributed by Mr Norman Wyld, treats of vitality, the divided labours of the body, and instinct The third par describes "The Forms of Animal Life" and includes chapters on the life-history of animals, and their past history as read in the geological record The fourth and last part treats of "The Evolution of Animal Life" and, besides a discussion of the influence of habits and surroundings, and of heredity, gives a sketch of the evolution of evolution theories Appendices on the relation of animal life to human life, and on some of the best books on animal life bring the work to a conclusion

The general arrangement of the subject-matter is, as will be seen by the above summary, well and carefully thought out, and the facts given in elucidation of the varied tendencies of organic development are skilfully marshalled and are derived from the most trustworthy sources The information given is therefore accurate and up to date The only suggestion we have to offer in this connection is that a little more selective elimination might have been exercised Some facts are given in so terse and condensed a form that no one but a zoologist could appreciate their value If a considerable number of these had been struck out and the space thus gained had been utilized in expanding those that remained, the Extensionee would have been the gainer "The Zoological Summary of the Animal Kingdom" (pp 210-272) might by some such process have been replaced by a sketch with more life and go in it As it stands it will, by many readers, be gracefully skipped

In such a work style is an important element Here Mr Thomson is often exceedingly happy He has imagination and a feeling for the poetic aspect of nature But his imagination and poetry need at times just a little chastening When he tells us that in birds "the breathing powers are perfected and economized by a *set of balloons around the lungs*," and that their brains "are not *wrinkled with thought* like that of mammals", when he speaks of the sponge as "*a Venice-like city of cells*", when he describes the ciliated cells of the windpipe as "*lashed* cells," or the embryonic membranes as "*birth-robes*," and when he says that in ponds subject to drought the organism often "*sweats off a protective sheath which is not a shroud*, and waits until the rain refreshes the pools", in these and sundry other cases of which these are samples, one may question whether the expressions which we have underlined are justified either by special elegancy or by real helpfulness to a beginner And this we say in no spirit of hypercriticism, but as desirous of aiding the author in what is by no means an easy task

Somewhat deeper would be our criticism of sundry expressions which are of essentially human implication and which in our opinion should not lightly be applied to animal activities. Much is said of the "love" of animals for their mates when some such phrase as "sexual appetence" would be more appropriate. For example, concerning ants we read :—"After this midsummer day's delight of love death awaits many, and sometimes most." And in the analysis of the forms of struggle for existence, we have the "struggle between rivals in love" Again, of the cuckoo it is said that, "in spite of the poets, the note of this 'blessed bird' must be regarded as suggestive of sin"! And again, "It is not quite correct to say that the cuckoo-mother is immoral because she shirks the duties of maternity, it is rather that she puts her young out to nurse because she is immoral' It is true that Mr Thomson adds this footnote —"The student will notice that I have occasionally used words which are not strictly accurate I may therefore say definitely that I do not believe that we are warranted in crediting animals with moral, æsthetic, or, indeed, any conceptions" We are glad to be thus assured But why implant notions in the text which have to be eradicated in a footnote? Does not Mr Thomson know how easy it is to sow tares and how difficult to root them out?

Mr Norman Wyld's chapter on "Instinct" is short, but quite to the point We hope that he may further observe and experiment in the field of comparative psychology, for he is fully alive to the peculiar difficulties of the subject, and there is a wide field before him in which the scientific workers are none too many In criticizing Mr Lloyd Morgan's definition of instincts as "oft-recurring or essential to the continuance of the species," Mr Wyld says —"This is not quite satisfactory, for many actions that are instinctive are not oft-recurring, and many are not necessary to the preservation of the species" He does not show that there are any such actions which are neither the one nor the other We have reason for supposing that he understood Mr Lloyd Morgan to say that instinctive actions were "oft-recurring *and* essential to the continuance of the species" But this he did not say

In conclusion we may repeat that "The Study of Animal Life," though by no means faultless, may be recommended to Extension students and the general reader as, in the main, accurate, readable, and suggestive

VECTOR ALGEBRA

Principles of the Algebra of Vectors By A Macfarlane, M A, D Sc, LL D, F R S Edin., Professor of Physics in the University of Texas Reprint from the Proceedings of the American Association for the Advancement of Science, Vol XL, 1891, pp 65-117 (Salem Press, Salem, Mass, 1891).

THIS is a very suggestive contribution to the foundations of the Algebra of Vectors as recently so strongly advocated in America by Prof Willard Gibbs, and in this country by Mr Oliver Heaviside

The extensive use of quaternions among physicists has been prevented by the fact that the meaning of a product of vectors has been made to depend on the use of a vector as a quadrantal versor, and by the fact that this method leads to the square of a vector being negative. The advocates of the new algebra define a product of vectors independently and in such way that the square of a vector is positive Rotations are expressed by means of dyadics, or ratios between vectors

and the quaternion notion of a vector being also a quadrantal versor is not entertained at all

The author of this pamphlet devotes a portion of it to the consideration of quaternions, which he holds should form a distinct algebra by themselves, and he suggests a special notation for them He restricts a quaternion proper to a *pure number* (a stretching factor) combined with a certain amount of turning A vector, on the contrary, may be a quantity of any dimensions, possessing direction, with no suggestion of turning attached to it

He clearly shows that the objectionable *minus* which occurs in scalar products in quaternions arises from the attempt to use the same symbol both for a quadrantal versor and for a vector, so that the laws established for dealing with one set of quantities may hold also for the other set, or for a combination of the two

It may be worth while to notice that this minus sign of the quaternionists would disappear as an explicit symbol if they considered the second vector as being drawn from the end of the first, as AB, BC, and then took the angle ABC as being the angle between the vectors—that is to say, if, in a polygon of vectors, they were to define the angles between the successive vectors to be the *internal* angles of the polygon Indeed, by many the internal angles of a polygon (or triangle) are considered as being *the* angles between the sides, though there is loss of real naturalness and of symmetry caused by so considering them for instance, the connection between A, B, C and a, b, c in a spherical triangle would be greatly simplified if A, B, C were to denote the *external* angles However, if we consider these internal angles to be the angles considered by the quaternionists, the reason for the square of a vector being negative appears at once, for if a be the quantitative part (freed from the notion of direction) of a vector **A**, we have $\mathbf{A}\ \mathbf{A} = a^2 \cos 180°$, **A** and **A** being consecutive sides of the polygon which have straightened out till the internal angle between them is 180°

It may therefore be contended that the quaternionists' *minus* is not quite irrational in vector algebra (though it cannot be said not to be inconvenient there), and that the advantage of being able to treat a vector as a quadrantal versor without having to establish a new set of formulæ far more than compensates for the loss of symmetry On the other hand, the advocates of vector algebra without the *minus* would probably reply that they have to deal with vectors which are not in any sense the same as quadrantal or any other kind of versors, and that the imaginary completeness gained does not in any degree whatever compensate for the loss of naturalness and loss of symmetry involved in the *minus*

The author differs from Prof Gibbs and Mr Heaviside in the mode in which he defines the product of two vectors, as he considers the *complete* product formed on the understanding that the multiplication shall obey the distributive law. He then finds that this complete product consists of a non-directed part, and of a directed or vector part, the former consisting of the product of the two quantities into the cosine of the angle between them, and the latter of the product of the two quantities into the sine of the same angle, having as axis the normal to the plane containing the two vectors The angle is the angle through which the first vector (occurring on the left-hand side of the product) would have to turn to make its direction coincide with that of the second

Prof Gibbs and Mr Heaviside, on the contrary, define the scalar product and the vector product as if they were entirely distinct and independent quantities Finally the same result is attained, but Prof Macfarlane's mode of introducing these partial products as arising naturally from applying the distributive law of multiplication would seem to have an advantage from the point of view of a student.

Prof Macfarlane dwells emphatically on the importance of considering *dimensions* of vectors, as well as their direction, and to emphasize this he separates his vector, not into *tensor* and *unit-vector*, but into *quantity* and *direction* Thus in the equation $\mathbf{X} = xi$, x is the quantity, and i denotes the axis Hence the equation $jk = i$ is not a violation of dimensions, but is merely a convention as to the interpretation of a composite direction, a convention, moreover, which could only be adopted in space of three dimensions, and is the statement that the plane in which j and k lie has its orientation sufficiently indicated by the normal direction i, with the further convention that the angle from j to k shall be considered positive

The author's notation is novel, and forms a very important feature in his treatment of the subject The scalar product of **AB**, which is $ab \cos (ab)$, he calls cos (**AB**) and the vector product he calls *Sin* **AB**, its magnitude, irrespective of direction, being denoted by *sin* **AB** Possibly an improvement in this latter would be to denote it by *sin ab*, and then the capital letter in the complete vector would become unnecessary

The particular symbol used to denote a scalar or a vector product is a matter of secondary importance, but is a matter which must sooner or later be settled if vector-algebra is to come into general use Lord Kelvin is of opinion that a function-symbol should be written with not less than three letters, and Prof. Macfarlane's notation obeys that law, and is moreover easy to work with, but is incomplete, being applicable to products of two vectors only Mr Heaviside uses no prefix at all to a scalar product, but considers that **AB** means the scalar product. He uses the quaternionic expression *V* **AB** for the vector product Prof. Gibbs uses no prefix for either, but denotes the scalar product by **A** **B**, and the vector product by **A**×**B** The three-lettered prefix seems the clearest in both cases to denote the special product intended, and the symbols *cos* and *sin* are more or less suggestive

In forming a product of three vectors, Prof Macfarlane makes the convention that **ABC** shall mean (**AB**)**C**, the combination commencing on the left. In his notation this product expands into

$$(\cos \mathbf{AB} + \mathrm{Sin}\,\mathbf{AB})\mathbf{C}$$
$$= \cos(\cos \mathbf{AB}\ \mathbf{C} + \mathrm{Sin}\,\mathbf{AB}\,.\,\mathbf{C}) + \mathrm{Sin}(\cos \mathbf{AB}\,.\,\mathbf{C} + \mathrm{Sin}\,\mathbf{AB}\,.\,\mathbf{C})$$
$$= \cos(\mathrm{Sin}\,\mathbf{AB}\,.\,\mathbf{C}) + \mathrm{Sin}(\cos \mathbf{AB}\ \mathbf{C}) + \mathrm{Sin}(\mathrm{Sin}\,\mathbf{AB}\,.\,\mathbf{C})$$
$$= \mathrm{vol}\,\mathbf{ABC} + \mathbf{C}\,.\,\cos \mathbf{AB} + \mathrm{Sin}(\mathrm{Sin}\,\mathbf{AB}\,.\,\mathbf{C})$$

which finally becomes

$$= \mathrm{vol}\,\mathbf{ABC} + \mathbf{C}\cos \mathbf{AB} + \mathbf{B}\cos \mathbf{AC} - \mathbf{A}\cos \mathbf{BC}\,;$$

where vol (**ABC**) denotes the volume of the parallelopiped of which **ABC** are three adjacent edges. The only objection to this name lies in its suggesting that **A**, **B**, **C** are *linear* vectors.

Here appears the defect in the author's *cos* and *sin* notation, in that it cannot be applied to the products of three vectors, or at least that the special reason for its use has disappeared, and the author does not suggest so applying it.

But there is a certain perspicuity attained by this very limitation of the *cos* and *sin* notation to the products of only two vectors, inasmuch as there can be no ambiguity in the meaning of an expression in which they occur, even if brackets are omitted or placed differently. Indeed, instead of cos (Sin **AB** **C**) the author writes cos (Sin **AB**)**C**, which seems a curious use of the bracket. But cos Sin **AB** **C**, or preferably cos **C** Sin **AB**, is just as explicit, and even cos Sin **ABC**, though wrong to write as being puzzling, can only have the same meaning.

The author concludes with short sections on dyads and matrices, on scalar- and vector-differentiation, including scalar-differentiation of a quaternion. On the last page are a series of propositions relating to the addition of scalar and vector quantities situate at, or passing through, specified points.

The pamphlet is confined solely to statements of principles and the section devoted to dyads and matrices is very condensed, so that it is not in any sense a text-book for students. It is rather a synopsis of the subject, with the introduction of a special notation which the author has found useful. A text-book of vector algebra, with examples showing its application to problems in geometry, mechanics, and general physics, and contrasting the method with the Cartesian method of treating the same problems, is much needed, as many physicists are becoming interested in the new algebra, owing in great measure to Mr. O. Heaviside's able exposition of its principles and applications in the *Electrician* and elsewhere.

THE LAKE OF GENEVA

Le Léman. Monographie Limnologique. F. A. Forel. Tome Premier. (Lausanne: F. Rouge, 189-.)

PROF. FOREL has been for some years occupied in studying the Lake of Geneva, and has now published the first instalment of the fruits of his labours. The work, when finished, is intended to be a complete monograph of the history of a single lake, and will be a most important contribution to an interesting branch of physical geography. In the present volume the geography, the hydrography, the geology, the climatology, and the hydrology of Lake Léman are discussed, after some introductory matter relating to the instruments employed in sounding with other preliminaries. But, though only a single volume, the work embraces so many questions that we must, for want of space, confine our notice mainly to one, which, of late years, has attracted the most attention, at any rate in this country, viz. What has been the origin of the lake basin? Was it formed by the old Rhone glacier or in some other way? The especial value of Prof. Forel's memoir is the number of new facts which it brings to bear on the problem thus propounded.

The Lake of Geneva, however it may have been caused, is more modern than the middle of the Miocene period. "Le lac n'existait pas encore, la vallée du Léman n'était pas même indiquée quand la mer helvétienne déposait les mollasses d'Epalinges et du Mont." Its slopes, and almost certainly its bed, are covered with glacial deposits, of later date than the formation of its basin. Terraces around its shore indicate that its waters once reached a higher level, the greatest elevation which can be identified with certainty, being about 30m. above the present surface. The next pause was at 10m., after that the lake sank (the fall always being rapid) to its present level. Traces of still higher terraces are to be found on the north shore, but as these neither can be identified on the opposite side, nor correspond with any natural barrier in the course of the Rhone below the lake, Prof. Forel doubts whether they indicate old levels of its waters.

Lake Léman consists of two basins. The first and larger extends from the embouchure of the Rhone to the narrow of Promenthoux. At the east end the slope of the cone of alluvium deposited by the Rhone in no part exceeds 25°. First comes a zone of very shallow water off the actual shore line; to this succeeds a more rapid slope, which gradually eases off as it descends. The current of the Rhone has made and maintains a well-marked channel in this mass of detritus, and the contour lines are affected down to 250m. At the embouchure of the Dranse, on the south shore, another alluvial cone has been deposited. This, however, is rather steeper, but it is much smaller, and does not perceptibly affect the course of the subaqueous contour lines below about 200m. On the north side of the basin the slope varies. Under the walls of Chillon the descent is rapid, amounting to 137 in 100; it is nearly the same near St. Gingolph on the opposite shore, doubtless indicating submerged crags; but it is generally more moderate. West of Vevay it is about one in four, whence it changes gradually to one in ten opposite to Ouchy.

West of this port the descent is still more gentle, and so it continues round the western end of the basin, the lip of the latter being 75m. below the surface. The contours of the south side correspond generally with those of the north, and the form of the basin is evidently related to the geology of the district, being narrower and steeper among the harder rocks at the eastern end. The deepest part is a large rudely triangular area, the apex pointing towards the west, and the base lying roughly north and south, extending from almost opposite to the embouchure of the Dranse to near Lutry. All this area is an almost level plain, for it is wholly below the 300m. contour line, but the greatest depth obtained was only 309.7m.

The Petit Lac may be described as a comparatively narrow and shallow trough, rising very slowly from a depth of about 70 to 50 metres, and then gradually mounting to the embouchure of the Rhone, its bed being slightly interrupted by five small shallow basins, which roughly speaking, have a linear arrangement, but their floors only sink four or six yards at most below the general level.

The lake to some extent is still held up by the huge mass of gravel brought down by the Arve, through which the two rivers have now cut their channels on either side of the plateau of La Bâtie below Geneva. But it is

in the main a true rock basin, though its bed no doubt is concealed beneath glacial deposits and the finer mud brought down by rivers This alluvium has been studied by Prof Forel, but into the matter we are unable to enter

Both the origin of lake basins in general and of that of Léman in particular are carefully discussed by Prof Forel He examines, only to reject as attended by insuperable difficulties, the hypothesis that it was excavated by the old glacier of the Rhone He shows that the subaqueous portion corresponds in its general features with a river valley, and is only a prolongation of that of the Rhone This valley was first defined at a very early period in the uprising of the Alps, its excavation progressed with their growth, it was practically completed at a time when they were higher, perhaps by some 1000 m, than at present Then the lake was formed by a general subsidence of the mountain region, the lowland remaining comparatively unaffected The movements of the parts depressed may have been to some extent differential, but this, in Prof Forel's opinion, is not a necessary assumption To us, however, it appears that it would be very difficult to explain the rock barrier at St Maurice between the upper and lower plains without some amount of differential movement Prof Forel's view, of course, is not novel, for it has been long maintained in England as a general explanation of the greater Alpine lakes by a few geologists, who never bowed the knee to the glacial Baal With their writings, however, Prof Forel does not appear to be acquainted, though they appeared in publications generally accessible

The remainder of the present volume is occupied by a discussion of the temperature, rainfall, and general hydrology of the Lake Léman region It is full of interesting facts and discussions, which we would gladly notice did space permit The book is well printed, and contains many illustrations, together with a large map of the lake on which the subaqueous contours are depicted If the book were less diffuse its scientific value would have been greater, but Prof Forel pleads in excuse that he aimed at writing a volume which would be also acceptable to the general public, or in other words, would combine meat for men with milk for babes As a comprehensive history of a lake is a great desideratum, it would be ungracious to find fault with Prof Forel's very natural desire to secure a large number of readers and of purchasers.

T G BONNEY

OUR BOOK SHELF

Horn Measurements and Weights of the Great Game of the World, being a Record for the use of Sportsmen and Naturalists By Rowland Ward, F Z S (London Published by the Author, 1892)

IN these days, when every one is striving to "beat the record," it is only right that sportsmen should have clearly put before them the results already arrived at as regards the size of the trophies and the weight of game-animals already obtained by their brother Nimrods. No one is in so good a position to do this as Mr Rowland Ward, to whose well-known "jungle" in Piccadilly all the leading shooters of the present day send their "heads" to be mounted and their "skins" to be stuffed. It is, however, much to be regretted that Mr Ward did not take into his councils some brother "F Z S" more versed in scientific knowledge than himself when he prepared this volume, or at any rate did not have the proof sheets revised by some zoologist with a good knowledge of the Mammalia The consequence of this want of foresight is that the nomenclature and localities upon which the importance of the records entirely depends are in a very confused state, and in many cases quite erroneous

Take the Deer (Cervidæ), for instance Of this family a very correct and accessible list, drawn up by the late Sir Victor Brooke, has been published in the "Proceedings" of the Zoological Society for 1878, which Mr Ward would have done well to follow But we find under the Sambur (*Cervus aristotelis*) a head from "Java," where this species certainly does not occur, recorded in the list Next to this (p 10) comes the "Central and South Indian Sambur, *Rusa hippelaphus*" (whatever this may be), but three out of the four specimens assigned to it are from Nepal! On the other hand, several heads from Java are attributed (p 22) to *Cervus rusa*, which is merely a synonym of *Cervus hippelaphus*

The heads of the large Deer of the Caucasus obtained by Mr St George Littiedale are assigned (p 28) to the Red Deer (*Cervus elaphus*) But we have good reason to know that they really belong to the Persian Deer (*C maral*), quite a different species

Looking over the list of Antelopes, we find similar errors prevalent, though perhaps not quite to so great an extent The specimens of the Chiru (*Panthalops hodgsoni*) are assigned to "India," whereas this Antelope is only met with in the snow-fields of Ladakh and Tibet Nor can the "Takin" (*Budorcas taxicolor*) be properly stated to be from "India" It occurs only in the Mishmi Hills on the frontiers of Assam

These and many like mistakes are the more serious as Mr Ward's volume is well got up, nicely illustrated, and likely to be frequently used by the sporting naturalist But the statements contained in it cannot be relied upon for scientific accuracy

Der Peloponnes Versuch einer Landeskunde auf geologischer Grundlage Von Dr Alfred Philippson (Berlin R Friedlander and Son, 1891-1892)

GREECE has hitherto been interesting mainly to scholars, archæologists, and lovers of art, and no doubt it is from their various points of view that the country will always be most eagerly studied The subject, however, has also elements of attraction for students of natural science, and it is to these elements, so far as the Peloponnese is concerned, that Dr Philippson has sought to do justice in the present work His results have been obtained by direct personal observation, and are set forth with admirable clearness The book is divided into two parts, the first of which is called "special," the second "general" In the "special" part the author deals with particular regions of the Peloponnese, in the "general" part he presents an account of the peninsula as a whole Dr Philippson is a careful and accomplished geologist, and has been remarkably successful not only in throwing fresh light on the geological phenomena of the country, but in showing their relation to the various orders of facts which come more especially within the province of the geographer He has also excellent chapters on the forms and phenomena of the surface, on climate, on vegetation, on the animal world, and on the population In dealing with the last of these subjects he has much that is valuable to say about productive industry, means of communication, density of population, and towns, villages, and other settlements. The interest of the work is greatly increased by maps and profile sketches

Traité Encyclopédique de Photographie By Charles Fabre (Paris: Gautier-Villars and Sons, 1892.)

IN a previous number of NATURE (vol xlvi p 464) we noticed the first part of the supplement which M. Fabre

proposes to bring out triennially. The present two volumes form a continuation, and extend as far as § 5 of the second chapter in the second book. The author proceeds on the same lines as formerly, and places before the reader in a concise way all the new methods of development, measuring lenses, apparatus, &c., from the particulars of constitution which characterize developers down to the latest form of kodak or tie camera. Not only is each subject treated with the greatest care, but illustrations are numerously distributed. That which will add great value to the work as a whole is the insertion of references, for what, after all, is more annoying than having to wade through a great quantity of literature when the presence of one or two words would have eliminated all trouble? W.

The Reliquary: Quarterly Archæological Journal and Review. Vol. VI. (New Series.) (London: Bemrose and Sons, 1892.)

THIS volume consists of the four numbers of *The Reliquary* which have appeared during the present year. The contents include many things which do not quite come within the scope of NATURE, but it is satisfactory to be able to note that the writers, speaking generally, have done their work in a thoroughly scientific spirit. Mr. J. Lewis André contributes an interesting and well-illustrated paper on leather in the useful and ornamental arts, and a clear account is given by the editor of a part of an early dial, bearing runes, which he was lucky enough to find some months ago in the churchyard of Skelton, Cleveland. An illustration gives a good impression of the general character of the stone, the runes on which, according to Canon Browne, are "Danish." Among the other papers are two articles, by Mr. D. A. Walter, on ancient woodwork, and a discussion, by the Rev. A. Donovan, of some of the problems connected with the career of Columbus.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Nova Aurigæ

ON October 5 the Nova Aurigæ was again observed under favourable circumstances, and the observation as to precautions in focussing necessary on account of chromatic aberration of the refractor was amply verified [NATURE, September 22, p. 489, in which note two corrections should be made: eighth line, for "varying" read "ranging," and fourteenth line, for "(? F)" read "(? G)"]. The line near C was distinctly seen at times, but the blue and violet lines observed on September 14 were not seen; the three green lines were very distinct.

On October 14 the red line was much fainter, but there was an obvious bright line in the yellow, which may be the line which Dr. Copeland estimated as 580 ± on August 28 (NATURE, September 15), or may be that which has been measured several times at the Lick Observatory (*Astrophysics*, October, p. 717), and appears to have a wave length of about 575. It had escaped my notice before, but I was induced to look most carefully in the yellow by considerations arising out of an attempt to reconcile Mr. Barnard's observations of apparent nebulosity surrounding the Nova, as seen in the 36-inch refractor at Mount Hamilton, with my own observations of September 14. Mr. Barnard's "stellar *nucleus*" was the difficulty. There appears to be no doubt that the Nova is emitting a spectrum similar to that of a planetary nebula, but it seems to me necessary to have further spectroscopic evidence before it is established that nebulous extension can be seen; if it is to be seen with a simple eyepiece, it must be looked for in a reflecting telescope, as the following considerations will show.

Prof. Keeler's study of the chromatic correction of the Lick Refractor shows ("Pub. Ast. Soc. Pacific," Vol. II. p. 164) that the circle of aberration of F light on the focal plane for the D line has a diameter which is in terms of the focal length 0.000349. We may take this diameter as very nearly that of the circle of aberration of D light on the focal plane for the F line. Thus if a star emits only D and F light, and the F light is focussed, then the D light will fill a circle nearly 7″ in diameter, and the star will look like a planetary nebula with a stellar nucleus. If the star emits light of wave lengths 500 and 575, then interpolation based on Keeler's measurements shows that round a stellar nucleus in the focus for wave length 500 there must be a circle of aberration of nearly 4″ diameter.

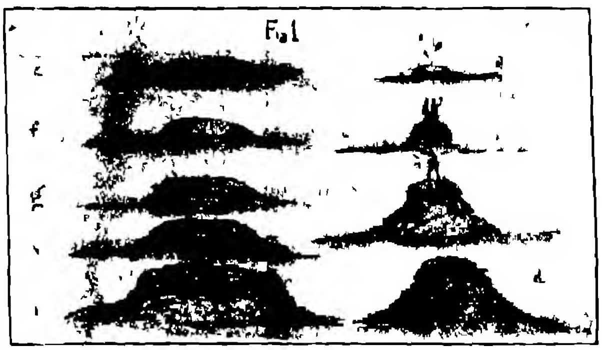
Mr. Campbell found lines of wave lengths 500 and 575 in the spectrum of Nova Aurigæ with respective intensities 10 and 1. Mr. Barnard describes the appearance of nebulosity as "pretty bright and dense," and as measuring 3″ diameter. My own inability to see either the circle of aberration for the yellow line when the green was focussed, or the alleged nebulosity, may be explained in several ways (*e.g.* smaller aperture of object glass, climatic conditions, &c.). The spectroscope could probably decide the question at Mount Hamilton by showing whether the *minimum* length of any of the lines is that corresponding with 3″ diameter on the slit. I have not been able to do more than observe that the yellow line is not visible when the 500 line is focussed on the slit of a spectroscope having an effective dispersion of two 60° prisms. H. F. NEWALL.

Observatory, Cambridge, October 24.

Formation of Lunar Volcanoes

WHILE we have, on the lunar surface, a series of markings so evidently volcanic that no one thinks of applying any other term to them, we have on the other hand no explanation of their mode of formation which will stand examination. The explanation given by Messrs. Nasmyth and Carpenter in their splendid work on the moon, founded upon explosive expulsion of lava, fails to satisfy the mind when applied to wide craters with a low wall such as Shickard or Grimaldi, of which there are so many on the moon, and which look more like some disturbance in a semi-liquid surface than an accumulation of volcanic débris.

The umbrella like eruption figured in Messrs. Nasmyth and Carpenter's book does not represent any phenomenon within our experience, as the erupted material (unless light enough to be driven by wind) invariably falls back into the neighbourhood of



the vent, and we could not conceive of its being shot neatly out twenty-five miles on every side to form the familiar ring.

An explanation of the mode of formation founded upon lunar tidal motion occurred to me about seventeen years ago, from observations on a cooling slag; but until the recent publication of Mr. Darwin's work on the history of the tides I was doubtful if that force were sufficient to account for observed results.

I had noticed that the rise and fall of a fused slag through holes in its solidifying crust, formed craters exactly like those in the moon; and I enclose a photograph of a piece of that slag in which is reproduced all the salient features of the lunar surface.

The mode of formation was as follows:—

The fused liquid (which was potash "black ash" containing a mixture of substances of very varied melting point) was still giving off some gas, which escaped as at *a* in Fig. 1, building up

a miniature crater as at b, c, d But the crater vent becoming intermittently choked, the accumulation of gas beneath the crust caused the liquid "lava" to rise through any neighbouring holes as at e, f, giving rise to a ring crater The pressure of the accumulated gas now drove out the obstruction in a, when the liquid lava receded in e as at g This intermittent action went on till the crater i was built up—entirely by "rise and fall" (as of a tide), no gas escaping at this hole

In the case of the moon the rise and fall would be caused by the tidal motion of the still liquid interior. The solid crust would resist the periodic rise of the liquid interior, and the liquid would well through the crust and recede again as the wave passed

When the crust was thin, and the lava very liquid, the large ring structures would be formed, as the lava would flow far, but

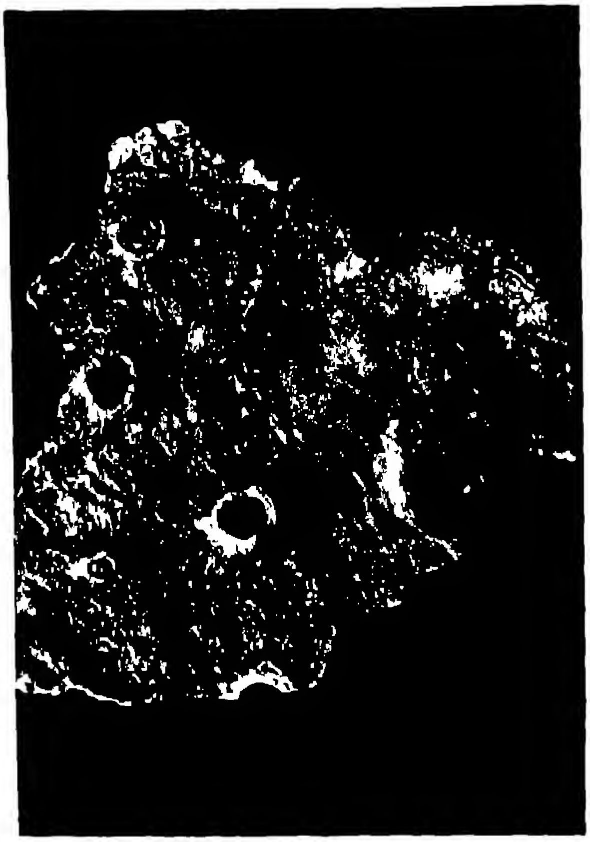


FIG. 2.

as the crust got thicker and the lava more viscid, the more striking craters like Copernicus would be built up. When the vent was very small, or the lava very viscid, the exuded lava would build up mountain ranges, or peaks like Pico, as it could not flow far, and would be cooled too much to allow of its flowing back with the ebb tide.

The existence of the cause proposed by Messrs Nasmyth and Carpenter, viz., expansion on solidification, is very doubtful. The proof they adduced was that a piece of solid slag would float on liquid slag. But when slag solidifies it becomes filled with small cracks, which doubtless contain air, and so aid in the flotation When I was working at this subject I had some slag poured into an iron mould kept cool by immersion in water. When the slag had cooled a distinct depression was seen on the upper free surface, showing that the slag had contracted during solidification. No doubt its contraction or expansion will depend upon its composition, and we do not know the composition of the moon's surface, but we need not depend upon a doubtful property for an explanation when a set of conditions have existed which must have yielded an ample force for the production of the observed results.

In the photograph marked Fig. 2, at a can be seen a crater with a raised floor and a central cone, at b a crater filled to the lip like "Wargentin," while on the plain near b, and round the open crater c, will be seen numerous minute craters, as on the moon's surface in the neighbourhood of "Aristotle" or "Copernicus," while in other photographs are seen walled plains like the "Mare Crisium," so that all the important features of lunar topography are reproduced in this slag, and there are many minor points of agreement which cannot be gone into in the limits of a letter.

Although I have always considered the tides the cause of the wonderful lunar configuration, I was not satisfied that that cause alone was of sufficient magnitude, till the work of Mr Darwin placed the matter in such a clear light that I now venture to submit the idea to your readers as a feasible explanation of the familiar lunar features J B HANNAY.

On the Need of a New Geometrical Term—"Conjugate Angles"

IN geometrical discussions, such as arise out of a great variety of physical problems, it is frequently necessary to refer to an acute or obtuse angle A as being equal to another acute or obtuse angle B, because contained by two straight lines which are respectively perpendicular to those containing the angle B Such a statement of the reason of the equality is, however, cumbrous Sometimes, indeed, such angles when acute might be described as equal because they are the complements of equal (because vertically opposite) angles, but it will often happen that the figure does not show the vertically opposite angles that would be referred to

I should be glad to know whether there is any term expressing the relation in question in use among either English or foreign writers, and, in default of such, would suggest that such angles be called *conjugate*, or if greater precision is required, *rectangularly conjugate*, the general term *conjugate* to be used when we wish to refer to an angle A as equal to an angle B because contained by sides whose directions are the directions of the sides of B, after each has experienced an equal and similar rotation in the plane of the diagram, whether the rotation is through a right angle or not

The shorter inclusive term *conjugate* could always be used for the less general but longer term *rectangularly conjugate*, when brevity was aimed at A M WORTHINGTON

Printing Mathematics

THE main features of mathematical work that give trouble in printing are three the expressing of (1) fractions, (2) powers, (3) roots

(1) To simplify the expression of fractions we have the solidus suggested by Sir G Stokes. But the solidus has been hitherto much less used than it might be, on account of the uncertainty as to how far its influence reaches in any expression more complicated than the simplest fractions This uncertainty can easily be removed, and the usefulness of the solidus greatly extended by defining more definitely its exact meaning. This is done in the simple conventions proposed below.

(2) To express the process of involution, the sign $\diagdown$, suggested by Mr C T Mitchell in the *Electrician*, is more concise and clearer than that mentioned by Prof S P Thompson in NATURE And Mr. Mitchell's sign, if defined by conventions similar to those applied below to the solidus, is capable of a like extensive application.

(3) To express roots we have the sign $\surd$ But, when accompanied by a horizontal line above to show the extent of its influence, this sign also requires special spacing But it can be brought into line with the rest by the use of the same conventions.

Taking then for

α. the sign of division	.. .	$/$
β. ,, ,, involution	..	$\diagdown$
γ. ,, ,, evolution	.	$\surd$

we may use each of these signs in either of two ways:—

I. Simply as a sign of operation, in which case it can influence only the quantities immediately adjacent to it

II In a double capacity—

(1) As a sign of operation.

(2) As one end of a bracket, of which the other end is | This bracketing influence may be directed either forwards or backwards, or both ways at once

Examples

a Division

$$\frac{a+b}{c} + d = |\, a + b/c + d,$$

$$a + \frac{b}{c+d} = a + b/c + d\,|,$$

$$\frac{a+b}{c+d} = |\, a + b/c + d\,|,$$

$$a\,\frac{b}{c}\,d = ab/cd, \quad a\,\frac{b}{cd} = ab/cd\,|,$$

$$\frac{a}{b+c}(d+e) = a/(b+c)(d+e),$$

$$\frac{a}{(b+c)(d+e)} = a/(b+c)(d+e)\,|,$$

$$\sin\frac{\theta}{n} = \sin\theta/n, \quad \frac{\sin\theta}{n} = |\,\sin\theta/n$$

Continued fractions also can readily be brought into one line by this notation —

$$\frac{a}{b+}\,\frac{c}{d+e+}\,\frac{f}{g} = |\,a/b + c/(d+e) + f/g\,|,$$

β. Involution

$$a^b = a\backslash b, \quad a^{-b} = a\backslash -b,$$

$$(a+b)^c + d = |\,a + b\backslash c + d,$$

$$a + b^{c+d} = a + b\backslash c + d\,|,$$

$$(a+b)^{c+d} = |\,a + b\backslash c + d\,|,$$

$$(a+b)^{\frac{c+d}{e+f}} = |\,a + b\backslash|\,c + d/e + f\,|$$

$a\backslash b/c$ and $a/b\backslash c$ are ambiguous, but $|\,a\backslash b/c = \frac{a^b}{c}$, because | being unnecessary for $\backslash$ in this case, can apply only to $/$. $\frac{(a+b)^c}{d}$ is $\|\,a + b\backslash c/d$, two vertical lines being required. Similarly $|\,a/b\backslash c = \left(\frac{a}{b}\right)^c$, $a/b\backslash c\,| = \frac{a}{b^c}$, $a\backslash b/c\,| = a^{\frac{b}{c}}$, $a\backslash b\backslash c\backslash d = a^{b^{c^d}}$.

γ Evolution—

$$\sqrt[n]{a+b+c} = |\,n\sqrt{a+b+c}\,|,$$

$$\sqrt[a+b]{c+d} = |\,a+b\sqrt{c+d}\,|,$$

$$\sqrt[a+b]{c} + d = |\,a + b\sqrt{c} + d,$$

$$a + b\,\sqrt{c+d} = a + b\sqrt{c} + d\,|,$$

$$a + \sqrt[b]{c} + d = a + |\,b\sqrt{c} + d$$

In some cases lines of differing thickness might be advisable, for instance—

$$\frac{b^{\frac{1}{2}}}{c(d+e)^3} = |\,b\backslash 1/2\,|\ /\,c\,|\,d + e\backslash 3\,|$$

There are many other ways in which this notation might be used; but the above will suffice to illustrate the advantages of it. And these advantages are substantial. It enables the work to be printed in the same space as ordinary letterpress, and thus avoids the special spacing, from which nine tenths of the troubles in mathematical printing arise. It requires no new types, except, perhaps, $\backslash$, and each of the signs used is suggestive of the original mode of writing for which it is a substitute. It can be used without confusion in conjunction with all ordinary brackets. How far this notation would suit very complicated expressions, is a point that would have to be determined by experience; but for printing mathematics of ordinary complexity it would be useful in economising space and diminishing the risk of printers' errors without any sacrifice of clearness.

Cambridge, October 27. W. CASSIE.

"Sunshine"

IN acknowledging the courteous criticism and the kind remarks which "C. V. B." has been pleased to make about my little book, may I be permitted to comment on one or two points, which I think he has imperfectly understood from the text. We all know that when "C. V. B." undertakes to review a book, he does his work in a thorough and searching manner, and from his critique it is evident that "Sunshine" has been well read. Notwithstanding this, in one or two of the instances selected for criticism the meaning, at once simple and obvious to a little child, who neither knows nor suspects any other, seems to have missed him, presumably because he knows all the bearings of the subject. Thus it is sometimes a disadvantage to be learned. Of this I propose presently to give an instance in the order which it occurs.

After poking fun at me, because, the "Sunshine" course being ended, Tommy meets King Sol face to face and "has it out with him," my critic proceeds to discuss the limits within which the imagination may be appealed to as a factor in scientific education, and while I agree with him in the main, I am tempted in passing to remind him of what Tyndall terms "the scientific use of the imagination," to which the clearness and (to me) the charm of his own lectures is largely due. Be that as it may, in one of "Nature's Story Books" I feel fully justified in employing, *within the limits of scientific accuracy*, any or all of the powers of the mind, which shall help children and others to *realise* the relation they bear to their surroundings, assured that in a course based upon some hundreds of experiments synthetically worked out and deductions made—a course whose main object is to lead children to go direct to Nature, *via* experiment, for their knowledge, there is little danger that the imagination be cultivated at the expense of the reasoning faculties. The experience of the writer is that the children attending the lectures became extremely critical—a state of mind which, although of inestimable value in acquiring knowledge, is not one of the happiest in other respects. Therefore it was thought desirable to provide them with some necessary ballast, and this is my defence of the hypnotic visit to the moon, and the other two chapters to which the critic alludes.

Natural science apart, it seems to me that the tendency of the school teaching of to-day is calculated rather to make children hard and matter of fact. For this reason I have endeavoured in these Sunshine Stories to interest children in the poetry of their common lives, myself playing somewhat the *rôle* of an optical instrument, presenting images sometimes real, sometimes virtual of those physical beauties which touch them at every point. The fact that "C. V. B." recognizes in "Sunshine" the *realism* which the "picturesque language" was intended to convey, disposes of the case of my Cape Town reviewer, who mildly insinuates that I have been guilty of some *fraud* upon little children in calling "Sunshine" a story-book. Therefore I am the more glad that "C. V. B." agrees with me that the mathematical side of these questions should not be obtruded. There are so many excellent text-books which supply that information for older pupils. I need not say that I shall be most happy to add the exception in the case of the rainbow. I thank him also for pointing out a passage in the notes where an additional clause is necessary, owing to the transposition of a paragraph. But I take exception to the statement about the top, for it is evident that the experiment is not made under the same conditions as that which "C. V. B." has in mind, because my boys get green and he gets (he says) white, or nearly white. The home experiment reads: "I am giving each of you squares of coloured paper to take home . . . then you may have the papers to put on your tops—*e.g.*, cover half blue and half yellow, spin the top and you will see green." A note on page 341 refers to the kind of paper. Now it seems to me from the expression "painted disc," which "C. V. B." has made use of, that possibly he may have had Clerk Maxwell's top in mind when he wrote.

When I say to a boy, "Here are two squares of paper, one blue and one yellow; when you've done so and so, you can have the paper to keep—cover your top, half yellow, half blue, &c.," the lad understands me, and when I am not there he takes out his halfpenny whip-top, tears a piece of the blue paper, and rendering it slightly adhesive hammers it down on the top with his right fist, he tears a similar piece and treats it in the same way, and so on until he has covered half. Then he takes the yellow paper and covers the other half with irregular patches of yellow. He spins the top and sees green.

How different is this from Clerk Maxwell's top Clerk Maxwell selected for his top the purest of paper and pigments He endeavoured to match the spectral colours (considerably diluted) He selected a scarlet red with a tinge of orange like *orange-red vermilion*, lying in the spectrum one-third the way towards D, between the lines C and D His green was one fourth the distance from E, between E and F, and resembled emerald green He also selected a blue violet midway between F and G, which was imitated by that purest of colours—ultramarine Now let us try the given experiment under the favourable conditions guaranteed by Maxwell's discs, viz, the purest of colours painted on Whatman's paper Taking up a disc of ultramarine and another of pale (not orange) chrome yellow, and concealing half of one disc behind the other, on rotating the compound disc so that the eye shall receive simultaneously blue and yellow light, the result is not white or even practically white, but a *grey, tinged with yellow* By a careful adjustment, hiding more of the yellow and exposing more of the blue (thereby *altering* the proportions of the text), it is possible to get rid of this yellowness and to obtain an absolutely neutral grey which it might be possible to persuade some grown up people represented white, but which on analysis yields 71½ per cent black to 28½ per cent white This may be proved by revolving a disc of black and white sectors in the above proportions, the results in each case being identical But even this result, unsatisfactory as it is, does not apply to the passage quoted in the text, in which no special conditions are observed. I maintain what is easily proved by experiment in less time than it takes to write it, that when ordinary colours, *e g*, gamboge and Prussian blue, are used, the residual light is green [1]

I fear that already this letter is too long, and since I do not wish to monopolize the space kindly placed at the disposal of your correspondents, I must defer the consideration of the annotations on soap films The other points are dealt with in the preface AMY JOHNSON

52 Lower Sloane Street, S W, October 12

I DO not think that the observations on my review of "Sunshine" require more than a very short answer

I considered that the authoress had not by any means cleared the confusion which usually exists as to the meaning of the expression "mixing of colours" It is applied both to the case where two or more colours are seen superposed, *e g* by spinning coloured paper where the resultant tint is due to the sum of the separate colours in the constituents, and to the case of mixed pigments where the resultant tint is that which is common to the constituents. Now as the common "paint box" rule says that blue and yellow make green, that is that blue and yellow pigments mixed produce a green pigment, it seems to me very misleading to say "Cover half (of your top) blue and half yellow and you will see green" Of course it may happen that the slight departure from white which will be observed may be in a greenish direction, but it may also be inclined towards pink, or, for anything I know, towards any other colour The one thing it will not do, however, is to make a green such as is obtained by mixing the pigments, and such as I fancy from the context any one would expect C V B

The Photography of an Image by Reflection

THE great utility of spark photography for obtaining time records of quickly-moving objects must be apparent to all who know the experiments of Mr C Bell, Prof Boys, and Lord Rayleigh. By means of spark photography the shadow of any object such as a jet of water, a flying bullet, or a broken soap film can be produced with perfect definition The shadow of the moving object illuminated by an electric spark is thrown on to a sensitive plate in a dark room, and the plate is developed in the usual manner The process of spark shadow photography will be found, I believe, of great service in physiological research With a view to try this I attached a long sensitive plate to the traversing carriage of a chronograph; the moving carriage closed and opened the primary circuit of an induction coil at prearranged equal intervals of time In front of the moving plate a frog's heart was placed in a slit on a screen, at each break a shadow of the heart was thrown on to the plate by means of the induced spark By this means thirty positions of the heart were registered, the pictures were all sharp and clear I have also used the same method for photographing the movements of insects

Since these experiments which I showed during the University Extension Meeting in Oxford this year, I have made several attempts to get spark photographs of the front view of objects (not their shadows) In my first experiments the objects were illuminated by an electric spark, the image being received on a plate in an ordinary camera I found that so much useful light was shut off by the lenses that only a dim picture could be produced A quartz lens was next tried and the results were rather better I then determined to use no lens, but in its place a silvered mirror A concave reflector made by silvering a concave lens of about 10 c.m diameter was so placed that it reflected the image of a white paper star 7 c m diameter, revolving about 60 times in a second, on to an ordinary photographic plate, the total length traversed by the light being 80 c m The star was illuminated with a spark exactly similar to that used in the previous experiment, on development a good picture of the star came out The reflector was neither well made nor well silvered The idea was suggested by observing some spark photographs I obtained of waves on the surface of mercury reflecting light When a steady light is used a photograph of any object is readily obtained by reflection from a suitable mirror Probably a steel surface would be best The mirror and plate were placed in a long box provided with a hole at one end through which the light reflected from the object passed A few experiments made on living objects to test the time of exposure in Reflection Photography showed that in order to avoid over-exposure, a very rapid shutter must be used

FREDERICK J SMITH

Trinity College, Oxford, October 25

Induction and Deduction

As your correspondent invites discussion on this subject I hope you will allow me to repeat in a new form the views I expressed upon it in your columns some months ago I quite agree with Mr Russel in maintaining that "true induction is utterly unable to yield us any conclusion that is more than probable and approximate," understanding by induction inference from one or more special cases to a more general rule But on the other hand it appears to me that Miss Jones's criticism is quite destructive of Mr Russel's interpretation of geometrical reasoning The point which both have missed I believe to be this, that a proposition stated in given words, such as the enunciation of Euclid's *pons asinorum* does not always and to every one convey the same information, and if it is meant in one sense its degree of reliability, and the method by which it must be proved, will be quite different from what they would be if it were meant in another There are at least three different kinds of interpretation which may thus be put upon the proposition It may mean (1) the triangle used to illustrate this proposition has equal sides, therefore it has equal angles, or (2) I have conceived a triangle which has equal sides, therefore I have conceived one which has equal angles, or (3) the connotation ascribed by the adjective "isosceles" implies the connotation "having equal sides"

It is not necessary for me here to dwell upon the distinction between the first two interpretations, but the difference between either of them and the third is that this latter gives us no information about any real thing or concept, but only about what is implied by using certain terms And this latter kind of information clearly does not require to be based upon any real knowledge of things, but may be based solely on definitions of words. Arguments with propositions interpreted only in this sense are what I call symbolic arguments; and symbolic conclusions therefore give no real information unless they can be interpreted by the aid of real assertions, such as "I can conceive," or "There actually exist, things possessing the connotations ascribed to these terms by their definitions"

If this distinction has not before been recognized, it is because in most logical discussions we can in this way give a real meaning to our arguments In elementary geometry, for example, we can—with more or less effort—conceive things, or even actually draw them, which answer to our definitions with sufficient accuracy. And, indeed, the reason why "Euclid"

[1] The purport of the experiment will be best understood if I state that it follows a series of chapters on colour, viz the rainbow, the spectrum, its composition by refraction and by reflection, while the last chapter discusses and explains, with experiments, the question of spectral lights *versus* pigments. The common surface papers, which the children are daily in the habit of using, are then analysed by the prism, and found to be anything but monochromatic

and "Newton" are generally considered to yield a more valuable mental training than such subjects as analytical geometry is that the older authors, perhaps because they were a bit afraid of purely symbolic argument, tried constantly to keep real pictures and ideas before the minds of their readers But even so our conviction of the truth of any but the simplest theorems of geometry depends chiefly on the symbolic argument, not on the realization in succession of the actuality of the relations and operations discussed in the course of the proof This is perhaps sufficiently obvious in the higher branches of even Euclidian geometry, but it becomes absolutely indisputable when we reach such theorems as "Any two conics in one plane intersect in four points" Not only may some of these points be at an infinite distance, but some, or all, may be what is called, on the *lucus a non lucendo* principle, "imaginary", that is, they may be such that they cannot be imagined by anybody, much less actually drawn

Accordingly I cannot admit that the theorems of geometry are established by induction at all If they are interpreted in either of the first two ways I have described, they are only particular propositions, and the inference from them to a general proposition would no more yield a "mathematical certainty" in this case than in any other And though the third way of looking at the proposition may be paraphrased into a form which appears general (*e g*, anything which may fairly be called "an isosceles triangle" may also be said "to have two equal angles"), it is really only a particular proposition about the words "isosceles triangle," and so on Its wide applicability and usefulness depends on the fact that we can, and do, often find things which can fairly be called isosceles triangles, but it must be admitted that the assertion that, on any given occasion, we have found such a thing,—is not a mathematical certainty If the triangle in question is an objective one, we can only say that it is probably, or approximately, isosceles, and though perhaps we may subjectively conceive perfectly isosceles triangles, and so regard the *pons asinorum* as a subjective necessary truth, it must be doubtful whether we could do so in the case of a more complex proposition such as Pascal's Theorem, and it is quite certain that we could not do so in the case of such theorems as that about the intersections of two conics

It is to be hoped, therefore, that logicians will come to recognize the importance of symbolic reasoning, as mathematicians have already done And when they do so we may hope for this further advantage, that they in turn will teach mathematicians and others not to confuse a purely symbolic with a real conclusion—not to assume that, because they have correctly proved a conclusion symbolically, that it therefore necessarily gives any information about real things, or even real concepts EDWARD T DIXON

Bell's Idea of a new Anatomy of the Brain

IN NATURE of October 27 the writer of the review of Mr Horsley's "Structure and Functions of the Brain," speaking of the rarity of the above book, states that he only knows of one copy in London, viz, that in the British Museum It may be useful to some of your readers to know that there is a very interesting copy in the library of the Royal College of Surgeons It is the presentation copy to Dr Roget "from Mr C Bell, 34, Soho Square", by Dr Roget it was given to Lady Bell, who presented it to the Royal College of Surgeons through Mr Alexander Shaw

Mr. Shaw has added in MS a copy of the letter received from the printers fixing the original date of publication, and also the list of persons to whom presentation copies were sent. The letter and the list are both published in Mr Shaw's reprint of the Tract in the *Journal of Anatomy*, vol iii, 1869.

JAS B BAILEY,

Photographic Dry Plates.

IN reference to "Prevention's" note on Photographic Dry Plates, one cannot but agree with him that packets should be dated when issued from the factory.

I would venture, however, to suggest that good makers' plates do not deteriorate within a reasonable length of time.

As an illustration of my experience I may mention that in April this year I opened a box of plates (½ plate Extra Rapid) which I bought in July 1886.

I had carried them on a three months' tour in the Mediterranean in 1888 and had taken no special care of them since

They proved in every way as good as new, both in sensitiveness, and perfection and evenness of film

ARTHUR E BROWN

THE GENUS SPHENOPHYLLUM

NOTWITHSTANDING the small size and comparative scarcity of the plants belonging to this Palæozoic genus, they have long attracted a rather unusual amount of attention This has been partly due to their peculiar external forms, which suggested even to the earliest observers the idea of resemblances to the Marsiliæ, but the interest they have excited has been further increased of late years by discoveries respecting the peculiar organizations of their stems In 1822 Adolph Brongniart assigned to them the name of "Sphenophyllites," and in 1823 Sternberg figured some of them under the generic title of "Rotularia"[1] Sternberg's figures appeared in his 'Versuch einer Geognostisch-Botanischen Darstellung der Flora der Vorwelt," which work is now best known through the French translation of it by Comte de Bray To the first of his specimens figured (*loc cit*, tab xxvi, figs 4*a* and *b*), Sternberg gave the name of *Rotularia pusilla*, and the example so designated is very characteristic of the simpler type of the group, in which we have a somewhat branched stem, with verticils of wedge-shaped leaves at each node A second form was figured on a later plate of the same work It is interesting to note that Sternberg associated with these figures the observation, "Plantæ organisatione foliorum Marsileis, forma caulis Hippuri Maritimæ" The generic name thus given by this author represents the rotate arrangements of the leaves in each verticil, as the wedge-shaped contour of each separate leaf is further indicated by Brongniart's generic term, "Sphenophyllites" In 1820 Von Schlotheim had also included similar examples in his too comprehensive genus, "Palmacites[2]"

In 1828 Brongniart published his classic "Prodrome d'une Histoire des Végétaux Fossiles," in which work we find the generic name of these plants changed to Sphenophyllum, which name they have retained to the present time In this work Brongniart examines in some detail the probable affinities of these plants, which even in 1822 he inclined to regard as having some affinities with the Marsileæ He defines them as having six, eight, ten, or twelve leaves in each nodal verticil, each leaf being wedge-shaped, sometimes entire, truncated at its apex, which is denticulate In some others these leaves are bilobed, and in other species they are not only profoundly bifid, but each of these lobes is either divided into two, or their ends are laciniated Lastly, in some cases the lobes become narrow and linear Brongniart here compares these leaves with those of Ceratophyllum and Marsilea, concluding with the statement, "We cannot for the moment decide between these two relationships" At this date the fructification was wholly unknown

In his introduction to the "Natural System of Botany," p 37, Brongniart again reverts to the idea that Sphenophyllum had Marsileaceous affinities.

In 1831 the authors of the "Fossil Flora of Great Britain" commenced their publication of that work, and in one of its early numbers they figured and described under the name of *Sphenophyllum erosum* what appears to be identical with the first figure published by Sternberg. When discussing the relationships of this plant, Lindley and Hutton

[1] These figures were preceded in 1709 by a still earlier one by Scheuchzer in his "Herbarium Diluvianum" (Coemans and Kickx, "Monographie des Sphenophyllum d'Europe").

[2] "Die Petrefactenkunde auf ihrem jetzigen Standpuncte."

reject Brongniart's idea of its possible affinity to the Marsileæ, inclining to the belief that it approached nearer to the Coniferæ, and especially to Salisburia. This impression they retained when, at a later date, they described a second species of the same genus.

In his "Tableau des Genres de Végétaux Fossiles," published in 1849, Brongniart returns to the subject. He here calls attention to the readiness with which Sphenophyllum may be confounded with the genus Asterophyllites, which some forms of the former genus closely resemble, but he again repeats that the two can be distinguished by the fact that in the former genus the leaves never exceed ten in number, whilst their form is triangular with a truncated summit. He again dwells upon the fact that in some Sphenophylla the leaves become so deeply lobed, narrow, and linear, as to be easily mistaken for those of Asterophyllites. He now affirms that the fructification is closely related to that of Asterophyllites.

As to the affinities of Sphenophyllum, Brongniart now asks, "Does the plant combine the leaves of a Marsilea with the verticillate of an Equisetum, or is it a Gymnospermous Phanerogam, the leaves of which approach those of the Gingko?" He does not answer the question, but concludes that this cannot be done until the fructification of the plant is better understood.

In 1864 a monograph on the species of the genus was published by M. Eugene Coemans and M. J. Kickz, but the authors make no serious effort to solve the vexed question of the affinities of the genus.

We now enter upon a new stage in the history of the genus. In 1870, M. Renault presented an important memoir to the French Academy of Science, which, for the first time, threw light upon the internal organization, especially of the stems, of Sphenophyllum. He described two examples, one from Autun and the other from St. Etienne, both of which exhibited a structure wholly different from that of any plant previously known, recent or fossil. In the centre of each stem was a primary vascular bundle, the transverse section of which was a triangle with three concave sides and three prolonged, narrow, intermediate arms. This axial organ underwent no subsequent growth after its first formation. But it was invested by a secondary zone, which was deposited upon the primary triangle layer after layer like a secondary xylem, producing a circular axis, which enlarged as the plant advanced in age. But this secondary growth did not consist of layers of vessels, but of vertical columns of thick-walled cubical cells. The cortex also exhibited specially distinctive features. These discoveries made it clear that Sphenophyllum constituted, not only a very distinct genus, but a type of plant far removed from everything previously described.

It fell to my lot to make the next advances in our knowledge of this genus. In 1871 I described in the memoirs of the Literary and Philosophical Society of Manchester a new fructification, to which further reference will be made later on. In 1872 I obtained from the Oldham deposits some new stems which obviously belonged to the same type as those discovered by M. Renault, but from which they differed in important points of detail. These were described in my Memoir, Part V., published in the Philosophical Transactions for 1874. Transverse sections of these closely resembled in their dominant features M. Renault's corresponding ones, but with two differences. When my plants attained to a certain stage of their exogenous growth, a well-defined circular boundary marked a temporary arrest of that growth, but which started afresh from a zone of much smaller vessels (*loc. cit.* Pl. II., Figs. 11 and 12), that increased in size as the diameter of the axis increased, as they had previously done in the more internal series. Still greater and more important differences presented themselves in the longitudinal sections. The zones of secondary or exogenously developed xylem, which in M. Renault's examples consisted solely of vertical columns of thick-walled, cubical cells, were composed, in mine, of true tracheidal vessels with reticulated (not with bordered pits) walls, presumably a higher stage of development. Another new and more advanced feature than characterise Renault's cells, seen best in tangential sections of this zone (*loc. cit.* Fig. 13), was the existence, between contiguous tracheids, of vertical, but interrupted, series of small cells, which I can only regard as rudimentary medullary rays. In the same memoir (*loc. cit.* Pl. IV.) a still more distinct form from the Burntisland deposits in Fifeshire was figured and described. M. Renault and Count Solms Laubach refuse to recognize a Sphenophyllum in this type, but they have not yet convinced me that I am in error on the point. The fact is that, though widely aberrant from the form described above, it scarcely differs more from that form than the latter does from M. Renault's examples.

But my Oldham specimens raised another debated question. When the Memoir V. was published, all authorities agreed that the maximum number of true leaves in each verticil was ten or twelve; that, however deeply subdivided, their outline was a sphenoid one, and not linear, and that they were multinerved. But I am still convinced that in my specimens there were more than twenty such leaves, that they were linear in outline, and had a single median nerve. It followed that, continuing to accept the existing definitions of the genus Sphenophyllum, my plant was Asterophylloid rather than Sphenophylloid. I am now prepared to admit that it is a Sphenophyllum, but only on the condition that we alter our definitions of the latter genus, and admit the possibility that some of the forms may possess twenty or more undivided and linear leaves. The accumulating evidence that the foliage of at least some of the Sphenophylla was dimorphic makes the acceptance of my proposition a matter of necessity.

Yet more recent researches have revealed new and important facts connected with the history of these plants. I have already alluded to the new fructification which I described in 1871, and to which I gave the name of *Volkmannia Dawsoni*. M. Renault's memoir already noticed was laid before the French Academy in May 1870, and noticed in the *Comptes Rendus* of that date, but owing to accidents growing out of the Siege of Paris, it was not published until three years later. Meanwhile my memoir on *Volkmannia Dawsoni* was published, and a copy of it forwarded to M. Brongniart. After giving details of the structure of the strobilus I arrived at the conclusion that "it is the fruit either of Asterophyllites or of Sphenophyllum."

Two years later M. Renault's memoir of 1870 was combined with a second one on the same subject, and published. It contained a note by M. Brongniart, referring to my memoir of 1871, in which note he says, "This work agrees in many important points with the results obtained a year previously by M. Renault, though Mr. Williamson was unacquainted with the article in the *Comptes Rendus* of May 30, 1870. The fossil plant studied by Mr. Williamson, and named by him *Volkmannia Dawsoni*, doubtless differs, at least specifically, from that described by M. Renault, by the form of the central vascular bundle, and by the absence of the zones of quadrangular cells which surround it in the French specimens, cells which in consequence of the thickness of their walls would not be readily destroyed."[1]

[1] M. Brongniart has here failed to comprehend an important point. The cells, the absence of which he notices, really belonged to the secondary xylem of the older stem, which did not become developed in the youngest twigs. But it was only upon these twigs that the fructifications were formed, and of which they were but extensions. Hence their absence was merely a consequence of difference of age, and not a feature of specific value.

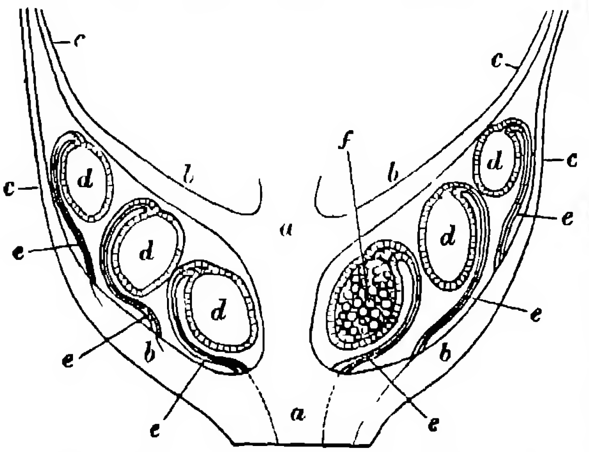
In 1890 I figured in my Memoir XVIII (Phil Trans 1890) a transverse section of what was obviously a stem of *Bowmanites Dawsoni*, in which the primary triangular axis of the strobilus was invested by a thick zone of the secondary xylem So far as the arrangement of its tissues is concerned this stem is constructed on exactly the same plan as appears in M Renault's and my own Sphenophylla. In describing it I further said, "We must unite Sphenophyllum with some forms of Asterophyllites in the same genus It is equally clear that Bowmanites, though its peculiar fructification demonstrates that it constitutes a perfectly distinct genus, has strongly marked features of affinity in the structure of its stem to the Sphenophylloid type"

The above reference to differences between the fructification of Bowmanites and of Sphenophyllum were based upon the minute description of the fruits of the latter plant, published by M Renault ("Études sur le Terrain Houiller de Commentry," pp 481-2) Those descriptions differ widely from what exists in my Bowmanites, but M Renault distinctly identifies them with the fructification of Sphenophyllum I obtained additional and important specimens of Bowmanites in 1890, which threw much new light upon its organization, and which were recorded in my Memoir XVIII (Phil Trans 1891)

In July last an important communication was laid before the Academy of Sciences by my friend M Zeiller, the distinguished director of the Superior National School of Mines at Paris In it he records his identification of a fructification of a Sphenophyllum of the type of *S pusillum* of Sternberg and *S erosum* of Lindley and Hutton, with my *Bowmanites Dawsoni* If this determination is correct, and I see no reason for doubting that it is so, we now have some more definite facts than we have hitherto possessed, guiding us alike in identifying the true fructification of Sphenophyllum and in determining its position in the vegetable kingdom

Before explaining M Zeiller's observations more in detail, a few words explanatory of the structure of Bowmanites will make M Zeiller's views more intelligible to the reader

The accompanying diagram represents two nodes and



one internode from a vertical section of this fruit, with the sporangia and three sporangiophores *in situ*.

So far as external contours are concerned, it is undistinguishable from many of the true Calamarian forms of fructification It is only when cut into sections that its characteristics can be discovered. Its central axis (*a*) has nodes (*b*) at short and regular intervals, and at each node is a verticil of from 16 to 20 sporophylles or fertile bracts (*c*). At their basal portions these bracts are coalesced into a lenticular disk (*d*), from the margin of which the thinner and narrowing bracts extend upwards, overlapping from two to three internodes. From the upper surface of the disk numerous slender sporangiophores (*e*) spring, each one proceeding upwards and outwards, to become attached to the *upper or distal* extremity of a large oval sporangium (*f*) Each of these sporangiophores has running through it a small bundle of barred tracheids, which terminate at the point of attachment to the sporangium Each tracheal bundle is a prolongation of one of a circle of similar ones that ascend from the central axis into the disks These fructifications, besides being manifestly eusporangiate, are extremely characteristic of the plant, nothing identical with them having been observed by any of the authors who have investigated the Carboniferous strobili After these illustrations I will allow M Zeiller to explain his views in his own words After referring to the details given in my Memoir XVIII, M Zeiller says –

"L'aspect de ces sporanges, ainsi attachés au bout de ces pédicelles recourbés, est exactement, à part les dimensions moindres celui de sporocarpes de *Marsilea* L'analogie parait du reste n'être pas purement superficielle, M Williamson a reconnu en effet, dans le pédicelle de chaque sporange, un cordon vasculaire bien caractérisé, qui prouve qu'on n'a pas affaire là à une simple formation épidermique, comme pour les sporanges de Fougères ou de Lycopodinées Il faut, à ce qu'il semble, regarder ces pédicelles comme représentant des lobes ventraux des bractées, analogues au lobe fertile des frondes d'Ophioglossées, ou à ceux des Marsiliacées, seulement ils portent à leur extrémité non pas une série de sporanges comme chez les premières, ou plusieurs sores comme chez ces dernières, mais un sporange unique à paroi formée d'une seule assise de cellules"

"De cette constitution des épis du *Sphen cuneifolium*[1] il report que, si les Sphenophyllum rappellent les Lycopodinées par la structure de leur axe, ils s'en éloignent notablement par la disposition toute spéciale de leur appareil fructificateur, qui tend à les rapprocher plutôt des Rhizocarpées, et qu'ils doivent donc bien décidément être considéré comme formant une classe distincte parmi les Cryptogames vasculaires."[2] Agreeing thoroughly with these conclusions further comments are needless WM CRAWFORD WILLIAMSON

DENDRITIC FORMS.

THE curious appearances presented by certain native specimens of silica have been observed for so long, that it is somewhat surprising that so little is known about their real constitution and mode of formation.

Rock-crystal is frequently found to contain bubbles of liquid, usually either water, carbon dioxide, or petroleum, or crystals, such as scales of mica, forming aventurine, and fibres, such as asbestos, forming cat's-eye. More rarely, however, forms of apparently vegetable origin are seen, one of the most remarkable specimens is a prolate spheroid, about five inches long and four inches across, cut from a clear colourless rock-crystal, in which are embedded numerous fragments about the size of a large pea, presenting the exact appearance of club-moss.

Agate is frequently found with distinct coloured layers, either flat or distorted, and usually milk-white, red, brown, or black. It is then known as onyx.

More rarely, agates are found with markings like moss or foliage distributed through them, they are then known as moss-agates, or Mocha stones

In 1814, Dr J. MacCulloch described some cryptogamic forms in the agates of Dunglas (Geological Trans, ii,

[1] The species of Sphenophyllum to which M Zeiller's strobili were attached.

[2] *Comptes Rendus des Séances de l'Académie des Sciences*, Paris, July 11, 1892.

iv, 398) It is stated that the Earl of Powys possesses an onyx containing the chrysalis of a moth

It seems to be generally assumed, without any strong evidence, that rock-crystal and agate have been formed from solution in water, possibly superheated, and that in such cases as those mentioned above, various crystalline or fibrous minerals and low forms of plant life have been inclosed during the process of solidification

Though this explanation is very possibly true in many cases, it does not account for all the appearances seen in moss-agates, and another possible mode of formation may be suggested by a brief account of some experiments made more than twenty years ago

Ordinary crystals of ferrous sulphate dissolve readily in cold water, but if they are placed in a dilute solution of an alkaline silicate, an entirely new series of phenomena are produced, which were first described by J D Heaton, M D, in a paper "On certain Simulations of Vegetable Growths by Mineral Substances" (Brit. Assoc Report, 1867, p 83) On immersing crystals of ferrous sulphate in a solution of sodium silicate of the density 1 065, very beautiful arborizations will soon begin to shoot perpendicularly upwards, attaining the height of three or four inches in a few hours In a weaker solution roots can be caused to shoot downwards from a suspended crystal The fibres contain silica and iron (less the weaker the solution), they are brittle, and more dense than the liquid in which they are formed Examined by the microscope, the ultimate ramifications are cylindrical, tapering tubes, the walls of which are granular, showing no sign of crystallization The roots are more abrupt and occasionally club-shaped in their terminations The growth is interstitial like that of organized living tissue "Supposing such purely mineral substances to have been formed in by gone geological eras, and to have been accidentally fossilized in some primary or other ancient rock, they would very probably, when discovered by recent investigation, be pronounced to be an evidence of organized beings having existed contemporaneously with the formation of such rock"

In the following year a similar observation was made by Prof W C Roberts-Austen (J C S, 1868, xxi, 274) A solution containing 49 per cent of silica, when allowed to gelatinize, and dried for two days over sulphuric acid, left a solid residue similar to opal from Zimapan, but containing 21 4 per cent of water All the specimens of jelly dried in air contained dendritic forms, varying in size from 0 2 to 0 5 mm When magnified 90 times they appeared as radiating fibres, when the power was increased to 700 times linear, each fibre resolved itself into a series of elongated beaded cells with clusters of circular cells at intervals Mr Slack indicated their remarkable analogy to common blue mould or mildew The cells appeared to be hollow, and did not blacken with sulphuric acid

A few years later I repeated Dr Heaton's experiments, and made some additional ones, a brief account of which may induce some one with better means at his disposal to investigate an interesting and somewhat neglected subject.

If a crystal of copper sulphate be suspended in a solution of potassium silicate, which has been carefully neutralized and has a density of 1 065, in the course of a few minutes a hollow green column will be seen to run down from the crystal to the bottom of the beaker. Sodium silicate may be used instead of potassium silicate, but the appearance and rapidity of the growth is somewhat changed The solution may be neutralized with hydrogen sulphate, chloride, or acetate, but hydrogen fluoride appears to prevent all growth. If the solution has a density less than 1 06, no growth occurs, and the crystals generally dissolve; the weaker the solution down to this limit the more rapid the growth. If the solution be stronger, the time required for the growth to commence may be lengthened from minutes to many days If the density be above 1 25, no growth takes place

Copper sulphate gives the best results, but it may be replaced by ferrous, manganous, or nickel sulphate, with changes in the shape, and of course in the colour, of the growths The growths take place most readily from a clean sharp crystal, and always from an angle or edge, an edge obtained by cleavage requires more time Other salts besides the sulphates may be used, but do not act so rapidly, probably owing to less perfect crystallization of the specimens used

In a neutral or very feebly alkaline solution the growths are comparatively rapid, and consist of long, branching, tapering fibres, not unlike the roots of a tree They grow rather more rapidly downwards than upwards If the solutions be decidedly alkaline, the growths are much slower, and consist of fine stalks with comparatively large lumps at the extremities

The tubes seem to be composed of silica with a small proportion of the metal used, they differ much in colour, are more dense than the liquid in which they grow, and are insoluble in water or dilute acids When magnified 100 times, the substance of the tube shows no appearance of crystalline form, but seems to consist of concretions of ovoid granules In this particular it differs from the substance of lead or silver trees, and from the curious fibres of potassium, iodide, and chloride described by Mr Warington (J C S, v, 136, viii, 31)

It is generally assumed that the formation of onyx is due to the successive deposition of layers of silica coloured by different substances, but the following experiment suggests another possible method of formation, especially when the extreme permeability of gelatinous silica by liquids is remembered So readily are even the hardest agates permeated by hot aqueous solutions of salts, that "staining" is a common commercial process

A little too much sulphuric acid was accidentally added to a moderately strong solution of potassium silicate in which some crystals of copper sulphate were lying The copper sulphate dissolved, and the solution set to a uniform blue jelly After standing for about a week, the blue colour at the top of the jelly had separated into a series of thin parallel coloured plates, leaving the jelly between them colourless This curious separation of the colouring-matter gradually proceeded downwards, and reached the bottom of the precipitating glass in about a month The jelly gradually shrank, dried, and hardened, forming fragments consisting of blue bands in a white mass

SYDNEY LUPTON

NOTES

THERE will be a memorial celebration for A W von Hofmann on November 12, arranged by the Deutsche Chemische Gesellschaft, at Berlin on the 25th anniversary of its foundation The Empress Frederick and many German and foreign celebrities have been invited to be present The proceedings, which will take place at the Berlin Town Hall, will include speeches on the history of the Society and on Hofmann, a review of progress in chemical science by Hr Wislicenus, and choral music, performed by the members of the cathedral choir.

WE regret to have to record the death of Mr. Robert Grant, F R.S., Professor of Practical Astronomy at the University of Glasgow He died at Grantown on-Spey, his native place, at the age of seventy-eight

THE death of Dr. Löwenherz, director of the Imperial Physical Institute, Berlin, has been announced. He died at Berlin on Sunday last

PROF VIRCHOW has been appointed an honorary member of the Imperial Russian Natural Philosophy Society

AN International ethnographical exhibition is to be held next year in St Petersburg It will be organized by the Russian Geographical Society

THE American Microscopical Society offers prizes for the encouragement of microscopical research, two of the value of 50 dollars each, and two of the value of 25 dollars each, for the best papers which shall give the results of an original investigation made with the microscope, and relating to animal and plant life respectively, also two of the value of 30 and 15 dollars respectively for the best six photomicrographs in some subject of animal or vegetable histology, and two of the same value for the best collections of six mounted slides illustrating some one biological subject

IN a letter to the *Times* on scientific titles and their abuse Prof Tilden has opened a subject of considerable interest to men of science It is well known that the letters indicating membership of a society are sometimes used by persons who have no right to use them, and Prof Tilden notes that an effort is to be made to deal with this evil by getting a Bill before Parliament "for the purpose of securing to the respective societies the copyright of these letters" This, however, is a comparatively unimportant aspect of the question The real difficulty is that membership of scientific societies is frequently "represented in courts of law or by candidates for public appointments as evidence of professional trustworthiness," whereas in very many cases it does not at all necessarily imply any extensive or accurate knowledge of the subjects in which the societies are especially interested "Fellowship of the Royal Society indicated by the letters F R S," says Prof Tilden, "is a real distinction which is justly prized But what is the public to understand regarding such alliterations as F B S, F C S, F E S, F G S, F L S, F S S, F Z S, and of F S A, M R I, F R A S, F R M S, F R G S, F R S E, &c? With the exception of one or two of the societies represented here, admission is to be gained by almost any one who is willing to pay the customary contribution to the funds of the society, and who can get two or more members of the society to testify to his fitness for admission, which generally means respectability and a profession of interest in the subject, the cultivation of which is the object of the society" He adds that if the public knew all about the societies no harm would arise, but "judges and barristers, and county councillors and town councillors cannot be expected to have this knowledge" Prof Tilden thinks that "the only chance for a better state of things is for every member of these societies who respects himself to abandon the use of these unmeaning letters altogether", but he fears that there is very little prospect of such a general reform while "an Institute having for its president no less a person than the Heir Apparent to the throne condescends to bait its advertisements for subscribers with the offer of more letters The *Times*, discussing the subject in a leading article, expresses the opinion that in the main "we must trust, imperfect though the security is, to the ability of grown-up men and women to protect themselves against a form of deception which has most hold over those who themselves covet the meaningless letters to which they blindly pin their faith."

THE weather during the past week has been characterized by a marked increase of temperature and excessive rainfall, accompanied by strong southerly winds and gales Between Wednesday the 26th and Friday the 28th October, the temperature in parts of England increased upwards of 30°, while the air became very humid and unpleasant. The continuance of comparatively high temperature, during which the thermometer reached 60° in the central and southern parts of the kingdom, was due to the track of the depressions, causing a continual indraught of warm air from off the Atlantic. On Thursday the 27th ult, about 1½ inch of rain was measured in the West of Ireland, and heavy falls occurred on the following days in the Midland counties A further downpour, amounting to 1½ inch in the Channel Islands, and to 1 3 inch in London, occurred on Sunday night, and the amount which has fallen on the east coast of Norfolk during the month of October is about equal to three times the average During the first part of the present week, the disturbance which caused the heavy rainfall passed away, and a small area of high pressure temporarily advanced over the United Kingdom from the Atlantic, while the temperature fell several degrees, with mist or fog in places, but conditions were very unsettled, and a change of wind to the south-eastward in Ireland gave indications of probable further disturbances During the week ended the 29th ultimo, the amount of bright sunshine exceeded the mean in nearly all districts

THE Meteorological Council have recently issued a summary of the *Weekly Weather Report* for the quarter ending September 1892 which shows the rainfall and mean temperature in each district for each similar quarter for the twenty-seven years 1866–92, grouped in five yearly averages, and also the means for individual years from 1881 The average rainfall of the quarter for the whole of the British Islands was 10 2 inches, or only 0 7 inch in excess of the mean for the whole period This result is almost entirely due to an excess in the grazing or western districts, amounting to 1 5 inch, while in the wheat producing or eastern districts the fall for the quarter is slightly below the mean The temperature for the quarter has been below the mean generally, for the whole of the country the deficiency amounted to 1° 8, and was 1° 7 in the grazing districts and 1° 9 in the wheat-producing districts Similar returns show that the excess of rainfall amounted to 1 5 inch in the same quarter of 1891, prior to which there had been a series of seven dry quarters, while the temperature has been uniformly below the mean for six corresponding quarters The coldest quarter was in 1888, when the deficiency amounted to 2° 5, this being, in fact, the coldest corresponding quarter during the last twenty seven years

THE late Mr George Grote, the historian of Greece, expressed in writing, eight years before his death, a desire that after his decease his cranium should be opened and his brain weighed and examined The task was undertaken by the late Prof John Marshall, and the results of his observations are set forth in a full report printed in the current number of the *Journal of Anatomy and Physiology*. The entire encephalon was somewhat above the average in size, if compared with the adult male brain at all ages If allowance be made for the effects of senile wasting, it must be regarded as a rather large brain, but not as an actually or especially large one There can be no doubt, however, that it was, at death, further diminished in size and weight through the effects of disease, as shown by its marked deviation from the ordinary ratio as compared with the body-weight. As tested by the standard of macrocephaly adopted by Welcker, its utmost allowable weight was below that standard, and as contrasted with the encephala of certain other eminent men, it would find its place about one-third up from the lower end of the list The general form of the cranium was rather or nearly brachycephalic, but it was decidedly higher than usual The cerebrum itself was, in accordance with the shape of the cranium, short, broad, and deep The cerebral convolutions were very massive, being not only broad and deep, but well folded, and marked with secondary sulci This condition was observable all over the cerebrum, but chiefly remarkable in the frontal and parietal regions Studied in reference to Dr. Ferrier's researches into the localization of function in the brain, the relative size of certain convolutions or groups of convolutions suggested some reflections as to individual peculiarities, but these reflections did not seem to Prof Marshall

to be quite trustworthy. From the size and richness of the convolutions, the sufficiency of the grey matter both on the surface and in the interior of the hemispheres, and from the remarkable number of the white fibres, especially of the transverse commissural ones, the brain of Mr Grote is pronounced to have been of very perfect and high organization

THE method of cleaning mercury adopted at the Physikalisch-technische Reichsanstalt at Berlin is described in the *Zeitschrift fur Instrumentenkunde* The raw material is brought in iron bottles from Idria It is filtered and dried, and twice distilled in a vacuum to get rid of the heavy metals Great care is taken to eliminate fatty vapours derived from greased valves and cocks, which is accomplished by means of a mercury pump working without a stopcock Finally, the electro-positive metals, such as zinc and the alkalies, are separated by electrolysis The mercury is precipitated from a solution of mercurous nitrate obtained by the action of nitric acid on excess of mercury The solution, together with the impure mercury acting as an anode, is contained in an outside glass vessel, into which a current from a Gulcher thermopile is conducted by an insulated platinum rod. The cathode rod dips into an interior shallow glass vessel, in which the pure mercury is collected On careful analysis it was found that no perceptible non-volatile residue was left by 200 grammes of the purified metal Thus the mercury is well fit for use in standard barometers and resistances.

WITH regard to the revival of animals after exposure to great cold, Herr Kochs (in the *Biologisches Centralblatt*) points out two things which retard formation of ice in the animal body First, the body does not contain pure water, but salt and albumen solutions, which only freeze under zero C Then capillarity and adhesion hinder freezing. Herr Kochs states that water in a glass tube of 0 3 to 0 4 mm. diameter may be cooled to $-7°$ and even $-10°$ C without freezing. With a diameter of only 0 1 to 0 2 mm. the water is not frozen, even though the end of the tube be put in freezing liquid Thin liquid sheets between two glass plates behave in the same way If a salt solution freezes, the salts are excluded, and pure water, in freezing, gets rid of its absorbed gas. Fresh blood, according to the author's experiments, freezes only after being strongly cooled to $-15°$C., and after complete elimination of gases and salts The blood corpuscles are dissolved and the blood loses colour. The same elimination doubtless occurs in freezing of protoplasm Experiments cited to show the possibility of "anabiosis" may probably be explained by the decomposition process not having gone so far as to bring life completely to a standstill Similar results were obtained in experiments on drying of seeds and various animals It was shown with what tenacity many animals, under most unfavourable circumstances, retain the moisture necessary to life.

THE very destructive American disease of the vine known as the "Black rot" has, for some years past, made its appearance in Europe, and its life-history has now been thoroughly investigated by Viala, Rathay, and others The ravages of the disease have been traced to a parasitic fungus, *Læstadia Bidwellii*, the mycele of which develops in the interior of the organ attacked, chiefly the young branches and berries, and produces spermogones and pycnids in the course of the summer. It is especially by the pycnospores that the fungus is disseminated. Towards the end of the period of vegetation sclerotes are formed, usually within the pycnids, and the conidiophores spring from these. Peritheces are also formed in May and June on the fallen and infected berries of the previous year. Until recently the ravages of this pest in Europe were confined to the French vineyards, but it has recently been detected in Austria and in Italy. The most effectual remedy for it is salts of copper.

THE results obtained from the botanical work done at the various experiment stations in the United States will in future be published in the form of an "Experiment Station Record," issued by the Department of Agriculture, under the editorship of Mr. Walter H Evans

ANGLO INDIAN papers record the presentation of an interesting "piece of architecture" to the Madras Central Museum by Lord Wenlock It is a hornets' nest, belonging probably to the species *Vespa cincta* It is conical in shape, and is constructed of a material resembling rough paper or cardboard composed of woody portions of plants gummed up by the insects, and brought into the condition of paste by means of a viscid salivary secretion. The combs are placed in tiers and attached to each other by small columns of the same paper like material of which the nest is composed It is two feet in height, and about the same in circumference at the base It was obtained in the course of one of His Excellency's tours

M DE NADAILLAC, in the current number of *La Nature*, discusses the significance of some of the facts which have been brought to light by the recent excavations of mounds in the Ohio Valley The mound builders knew how to construct earth fortifications, which were of considerable extent and always remarkably adapted to the sites chosen They buried their dead under tumuli of astonishing dimensions Copper was the only metal they could work, and they undertook long journeys in search of it. Their weapons and implements were of stone They made vases of pottery, and were able to produce representations of the human figure and of animals, both by sculpturing them in stone and by modelling them in clay. At least in some districts they were sedentary, and, like all sedentary populations, they had to obtain the means of subsistence in part by cultivation of the soil They were often engaged in fighting, and numerous burials in which the bodies are crowded together bear witness to the fury of their struggles Whence did they come and who are their descendants? M de Nadaillac thinks that these questions can never be definitely answered unless investigators discover some traces of the language of the mound-builders

AN interesting and valuable paper on the association of shipping disasters with colour-blind and defective far-sighted sailors, read by Dr T H. Bickerton before the section of Ophthalmology at the last annual meeting of the British Medical Association, has been reprinted for the author from the *British Medical Journal* Dr. Bickerton takes anything but a hopeful view of the prospects of legislation on this important question. He greatly fears that "many a shipping disaster will occur before the Royal Society's suggestions become part of the law of the land." Accordingly he urges all who interest themselves in the subject to abate not a tittle of their endeavours. "There are none," he says, "so difficult to convince as those who will not believe, and the men who have had the framing of the rules of the road at sea are the very men who hitherto have turned from all suggestions on the eyesight question with contempt. True it is that their language, judged from examples to be found in the *Nautical Magazine*, is becoming moderate, and even polite, but they lack knowledge of this subject, and they will still require our best attention" Meanwhile, Dr. Bickerton presses on the attention of the public the following facts.—that 4 per cent. of the whole male population are colour blind, that about 8 per cent. more have marked impairment of sight from refractive errors; that there is no official test whatever as to a sailor's eyesight; that a man may be the subject of any of the forms of eye disease, may have any degree of blindness, or may be so short-sighted as to be unable to see distinctly more than a few inches in front of his nose, and yet be at perfect liberty to be a sailor and to become an officer; and that, although there is a

compulsory colour examination (in many cases a most inefficient one) to be passed before a sailor can become an officer, there is no check to a colour blind man being a sailor, or to his remaining one to his life's end

THE Rev T A Marshall describes in the November number of the *Entomologist's Monthly Magazine* a new genus and species of Belytidæ from New Zealand The paper is accompanied by representations of two insects in fine condition Mr Marshall abstains from giving tedious details, as the figures will, he believes, convey a better idea of these creatures than many words, and he thinks they will now be unmistakable, at least until other species of the same genus shall be discovered He has not taken any characters from the under-side, the specimens being carded, hence the oral organs could not be described, but they may be pretty safely assumed to resemble those of *Belyta, Anectata*, &c, and their details would have been of little value

A CORRESPONDENT of the New York journal *Electricity*, writing from Paris, describes some electrical peculiarities which he has seen in a cat This cat, called Michon, is a half wild animal, and dislikes handling It belongs to the household of Dame Gais, whose residence on the Carnier Monnt, near Monte Carlo, looks directly down on the noted gambling casino and its botanical reservation On some of the cold and very dry nights common to Monte Carlo in the winter, Michon, while in the dark, is quite a spectacle Every movement of its body sends off hundreds of minute bluish sparks, something like those thrown off by ill-adjusted brushes, though not so pronounced in colour. They make a noise on a small scale, like the crackling of burning furze Stroking the cat increases the sparking, and ruffling its fur the reverse way produces a miniature pyrotechnic display quite remarkable The cat itself does not seem to mind the sparking, but, like all cats, dislikes to have its fur rubbed in a wrong direction The writer has never seen the electric element so abundant in a cat, and many who have seen the coruscations that have given notoriety to Michon, confirm him in the opinion that the cat is an electrical curiosity

A USEFUL account of "Biological Teaching in the Colleges of the United States," by Prof John A Campbell, of the University of Georgia, has been issued by the United States Bureau of Education The writer's object is to present the actual extent and scope of the biological courses offered by the colleges of the United States, together with the methods of teaching employed. He also aims at presenting as fully as possible an account of the equipment and facilities for teaching which the various colleges possess The statements he makes are therefore based largely upon the printed accounts found in the college catalogues, supplemented in many cases by letters containing additional information These have usually been re-written, but where they are in suitable form they are quoted directly Prof Campbell notes that many of the colleges announce more in their catalogues than they can possibly do thoroughly with the teaching force employed. This is often perfectly apparent, but in more than one letter received the statement has been made that certain courses have no existence save on paper Prof Campbell, however, thinks that it is worth while to record the views of the professors in charge in regard to the nature and aims of such work, and the ideals towards which they are striving.

THE "Treatise on Hygiene and Public Health," edited by Dr. T. Stevenson and Mr. Shirley Murphy, and reviewed in NATURE last week, is published by Messrs. J. and A Churchill.

MESSRS J AND A. CHURCHILL are publishing a second edition, revised and enlarged, of "Commercial Organic Analysis," by Alfred H Allen The second part of the third volume has just appeared The third part of the same volume will be issued as soon as possible, and will complete the work In the second part he has sought to describe fully and accurately such of the organic bases as have any practical interest, and to give trustworthy information as to their sources

THE new number of *Natural Science* includes articles on the evolution of consciousness, by C Lloyd Morgan; primæval man a palæolithic floor near Dunstable, by W G Smith, the evolution of sharks' teeth, by A S Woodward, the walk of arthropods, by G H Carpenter, the falling of leaves, by A B Rendle, and Norwich Castle as a museum, by H Woodward

A REVISED edition of "London Birds and London Insects," by Mr T Digby Pigott, has been issued by Mr H Porter Along with the essays on these subjects have been printed several other bright and attractive sketches

AN elaborate index to the genera and species described in the "Palæontologia Indica," up to the year 1891, by W Theobald, has just been issued It is included among the Memoirs of the Geological Survey of India. Mr Theobald has also prepared "Contents and Index of the Memoirs of the Geological Survey of India, 1859 to 1883"

A SECOND edition of Dr F H Hatch's "Text-book of Petrology' has been issued by Messrs. Swan Sonnenschein and Co. The author explains that he has taken advantage of this opportunity to revise the book thoroughly, while largely increasing its scope

THE Society for Promoting Christian Knowledge has published a second edition of Klein's "Star Atlas" Mr E. McClure, the translator of Dr Klein's explanatory text, has sought to bring up to date the German writer's descriptions of the more interesting fixed stars, star clusters, and nebulæ

MESSRS ROBERT GRANT AND SON, Edinburgh, and Messrs Williams and Norgate, London, have issued Parts II. and III of Vol XXXVI of the Transactions of the Royal Society of Edinburgh The following are the subjects of some of the papers:—the foundations of the kinetic theory of gases (IV), by Prof Tait, the solid and liquid particles in clouds, by J. Aitken, the development of the carapace of the chelonia, by J B Haycraft, the composition of oceanic and littoral manganese nodules, by J Y Buchanan, the winds of Ben Nevis, by R. T Omond and A Rankin, and the Clyde sea area, by H R Mill

THE University College of Wales, Aberystwith, has issued its calendar for its twenty-first session, 1892-3

THE City and Guilds of London Institute has issued its programme of technological examinations for the session 1892-93.

MESSRS GEORGE PHILIP AND SON announce that a work on "British New Guinea," by Mr J P. Thomson, Hon Sec. to the Brisbane Branch of the Royal Geographical Society of Australasia, is almost ready for publication. An appendix will contain contributions to the geology, fauna, flora, &c., by Sir William Macgregor, K C M.G, Baron Ferdinand von Mueller, Professor Liversidge, F R S, and others. The proof sheets have been revised by Dr H Robert Mill and Dr. Bowdler Sharpe.

ANOTHER and apparently much more convenient mode of preparing glycol aldehyde, CH_2OH CHO, the first member of the series of aldehyde-alcohols, is described in the current number of the *Berichte*, by Drs. Marckwald and Ellinger, of

Berlin It may be remembered that in our note of a fortnight ago (vol 46, p 596), it was announced that Prof Emil Fischer and Dr Landsteiner had succeeded for the first time in preparing this interesting substance in a state of tolerable purity by a reaction analogous to that of barium hydrate upon acrolein dibromide, the reaction which yielded the first synthetical glucose They first prepared the mono-bromine, derivative of common aldehyde, $CH_2Br\ CHO$, and subsequently reacted upon this new substance, a liquid possessing an intolerably sharp odour, with baryta water After removal of the baryta by sulphuric acid, and the hydrobromic and sulphuric acids by means of carbonate of lead, a liquid was obtained which possessed the properties of a dilute solution of glycol aldehyde Some time ago Pinner obtained a derivative of this aldehyde which bore the same relation to glycol aldehyde, that the compound known as acetal, $CH_3\ CH\langle{}^{OC_2H_5}_{OC_2H_5}$, bears to common aldehyde This substance, glycol acetal, $CH_2OH\ CH\langle{}^{OC_2H_5}_{OC_2H_5}$, Pinner attempted to decompose, by the action of mineral acids, into ethyl alcohol and glycol aldehyde The attempt, however, did not succeed, inasmuch as the decomposition went further, any glycol aldehyde that may have been formed during the first stage of the reaction being subsequently broken up Drs Marckwald and Ellinger now find that the reaction succeeds admirably, provided the acid employed is extremely dilute, and as glycol acetal is a substance very easily prepared, they show that the reaction affords a very convenient and advantageous method of preparing large quantities of glycol aldehyde The glycol acetal is added to an equal volume of water acidified with only a few drops of sulphuric acid. The liquid is then heated to boiling After a short time the two liquids mix, and the reaction is completed when upon the addition of water to a few drops of it no separation of oil occurs Upon distilling the liquid product, alcohol first passes over, then there distils a mixture of water and glycol aldehyde until decomposition of the residue commences Glycol aldehyde, as thus obtained in a tolerably concentrated form, appears to be much more volatile in steam than was observed by Prof Fischer and Dr Landsteiner, in case of their more dilute solutions From a few cubic centimetres of the distillate Drs. Marckwald and Ellinger obtained a very considerable quantity of Prof Fischer's phenylhydrazine compound, and confirm in every detail the other properties of glycol aldehyde described in our previous note above referred to The chemistry of this first member of the series which includes the sugars is now, therefore, fairly complete, and the difficulties in the way of its preparation surmounted

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♂) from India, presented by Mr Pascoe Grenfell, F Z S, a Philantomba Antelope (*Cephalophus maxwelli*) from West Africa, three Gambian Pouched Rats (*Cricetomys gambianus*) from West Africa, a Ground Rat (*Aulacodus swindernianus*) from West Africa, and a White-faced Tree Duck (*Dendrocygna viduata*) from West Africa, presented by Mr. C B. Mitford; a Martial Hawk-Eagle (*Spizaetus bellicosus*) from South Africa, presented by Mr T. White, two Weaver Birds (*Hyphantornis sp. inc.*) from South Africa, presented by Mr A W Arrowsmith, two Silver Pheasants (*Euplocamus nycthemerus* ♂ ♂) from China, presented by Mr. E Mitchener, a Common Chameleon (*Chamæleon vulgaris*) from North Africa, presented by Miss Kate Higgins; a Thick-tailed Opossum (*Didelphys crassicaudata*) from South America, a Garden's Night-Heron (*Nycticorax gardeni*); and two Saracura Rails (*Aramides saracura*) from South America, purchased, and a Squirrel Monkey (*Chrysothrix sciurea*) from Guiana, deposited

OUR ASTRONOMICAL COLUMN.

COMET BROOKS (AUGUST 28) —The following ephemeris, which we take from *Astronomische Nachrichten*, No 3125, gives the apparent Right Ascensions and Declinations of Comet Brooks, which is brightening very rapidly —

12h Berlin M T

This comet will still be found to form approximately an equilateral triangle with α Aquilæ and β Delphini on November 5

TABULAR HISTORY OF ASTRONOMY TO THE YEAR 1500 A D —Dr Felix Muller, of Berlin, has just completed a small volume entitled "Zeittafeln zur Geschichte der Mathemathik, Phisik und Astronomie bis zum Jahre 1500," which will be welcomed by all interested in the very early history of the exact sciences. The book is arranged chronologically and gives a short account of the chief workers in these branches of science up to the year 1500 At the end of each reference a list of the literature likely to be needed is added The work is published by Messrs. B G Teubner, Leipzig

A LARGE TELESCOPE —The Americans seem to have made up their minds to be the possessors of the largest telescopes in existence, for in spite of their owning the great Lick Refractor (36-inch) we hear now that the University of Chicago are about to have "the largest and most powerful telescope in the world" This instrument will be the gift of Mr Charles Jerkes, and will cost half a million dollars The object glass will have a diameter of 45 inches and will be made by Messrs. Alvan Clark, of Cambridge, Mass.

THE ATMOSPHERES OF PLANETS —Of all the planets that revolve round our sun, Jupiter affords the most suitable of them for the study of atmospheric circulation That his circulation will not be exactly like ours will be at once evident, for not only does the sun pour his rays on his vast surface, but he possesses himself heat, as is suggested by the rapid changes which these cloud masses undergo A recent hypothesis, explaining the various movements in this planet's atmosphere, has been put forward by Mr Marsden Manson, in the fifth number (vol ix.) of the "Transactions of the Technical Society of the Pacific Coast," San Francisco. The chief element which produces these movements is the action of the sun, and it is on this reasoning that he attempts to unravel the laws underlying the circulation in Jupiter's atmosphere In this pamphlet he first brings together some of the facts relating to our own wind system, which are generally conceded, together with the important results that were gathered from the path taken by the Krakatoa

dust-cloud. The spots observed on Jupiter's surface are next dealt with, a table of their rotation periods and latitudes being included. From the latter he deduces that the mean periods of rotation of matter in the following latitudes are:—

Lat.			h.	m.	s.
12° N.	from 17 N. Temp. spots		9	55	36.49
4° N.	,, 5 N. Equat.	,,	9	50	40.06
8° S.	,, 21 S. Equat.	,,	9	50	22.4
30° S.	,, 3 spots		9	55	17.1

In treating of the spots themselves, he suggests that those which are of a white appearance are gyrating uprushes of warm air from the lower regions, while the dark ones are simply descending columns of cool air, "the two forming parts of the system of vertical circulation." The red spot, he suggests, is caused by a local escape of internal heat, the repellent force it appears to possess being due to the "spreading of the heated currents as they rise." He explains the retardation and acceleration of its period of revolution by the increasing force of the west winds, brought about by the exposure of the southern hemisphere during Jupiter's half-year (5.93 of our years), in this way the spot is sometimes situated over and sometimes to one side of the source of heat underneath. The author also deals with other spots in a similar manner.

GEOGRAPHICAL NOTES.

MR. SVEN HEDIN's account of his ascent of Mount Demavend is published in the last number of the *Verhandlungen* of the Berlin Geographical Society. Demavend is a volcanic peak rising abruptly from the sedimentary rocks of the parallel Elburz chains. Starting from the village of Ranah on the south-eastern slope with two guides on July 10, 1890, Hedin reached the summit on the afternoon of the next day. On the summit a large elliptical crater was found, the edges of which were strewn with blocks of porphyritic lava and sulphur. After discussing the aneroid and boiling point observations, Mr. Hedin arrived at 5465 metres (17,930 feet) as the height of the summit. This is lower than any of twelve earlier estimates which are cited, the highest of them being 6559 metres.

THE Italian possession of Eritrea on the coast of the Red Sea gives some promise of becoming useful agriculturally. Several small settlements of Italians on the plateau have succeeded in growing large crops of wheat and barley, and only the unsettled state of the surrounding natives threatens the prosperity of the farmers. The districts of Ocule Cusai and Guro are already fully cultivated, and Sarae, as yet almost unoccupied, has fertile land and plenty of room for colonists. The Italians are able to work in climatic conditions which would rapidly exhaust the natives of northern Europe.

THE general summary of Mr. Conway's expedition in the Karakoram range telegraphed from India (p. 525) has now been supplemented by a full narrative, written to the secretaries of the Royal Geographical Society from a camp on the Baltoro Glacier on August 29, with a postscript added at Skardo, on the way to Leh, on September 12. The difficulties of the preliminary journey were very great, not the least being the fording of several swollen glacier streams by a party numbering four Europeans, four sepoys, seventy coolies, an indefinite number of followers, and flocks of goats and sheep. The moraines on the Baltoro glacier were of almost incredible extent, for two thirds of its entire length the ice is entirely concealed by stones, except where crevasses or lakes occur, and the irregularity of the surface made travelling extremely slow. Mr. Conway limits the name of Godwin-Austen to the highest peak of "K²," giving to the whole mountain the somewhat cumbrous title of the Watch Tower of India. One branch of the Baltoro Glacier results from the union of seven glaciers from this mass; the larger branch descends from the snow-swathed, throne-shaped mountain, hitherto unmapped, for which the auriferous quartz found in its rocks suggested the name of The Golden Throne. This was fixed upon as the goal to be attained. The first attempt landed the Europeans and Ghoorkas, who made excellent climbers, on Crystal Peak, 20,000 feet in elevation, a peak as hard to climb as the Matterhorn, and isolated from the surrounding higher summits. No inconvenience was felt from the rarity of the air, and the party remained on the summit for an hour and a quarter. In the grand attempt on the Golden Throne serious difficulty was encountered from the terrible extremes of heat and cold. The last few thousand feet proved very exhausting, one of the Ghoorkas had to be left behind, suffering from mountain sickness. Every step had to be cut in hard ice. Finally the summit was reached at an elevation of 23,000 feet, but the Golden Throne stood revealed much higher, and separated by a deep depression. From the summit of Pioneer Peak, probably the highest yet reached by man, a series of photographic views was obtained and prismatic compass bearings taken to the surrounding features. As long as the party were at rest they felt no discomfort, but the sphygmograph showed that the heart's action was very laboured. A stay of an hour and a quarter was made on the summit, the view from which baffled description. The descent was safely made, but fatigue and bad weather stopped further exploration.

THE INSTITUTION OF MECHANICAL ENGINEERS.

ON the evenings of Wednesday and Thursday of last week, the 26th and 27th ult., an ordinary general meeting of the Institution of Mechanical Engineers was held in the theatre of the Institution of Civil Engineers, by permission of the council of the latter Society. The President, Dr. William Anderson, occupied the chair during the proceedings.

There were two papers on the agenda. The first was the report of the Institution's committee appointed to enquire into the value of the steam jacket. Mr. Henry Davey is the chairman of this committee, and he had prepared the report, which is a bare record of facts without comment, and in this respect is, we think, defective. Numberless experiments have been made in time past as to the value of the steam jacket, and those now added by the labours of the committee do not largely differ from many that have gone before. We take it that the general opinion of competent engineers is that an advantage in efficiency is to be obtained by jacketing engine cylinders in an efficient manner, and cases in which the jacket has not been proved efficient are those in which it has not been properly applied. What was wanted, therefore, was guidance as to the proper method of application, and it is significant that the most help in this direction came, during the discussion, from those who were not members of the committee. Timidity in expressing opinion will be excusably construed as indicating something of incompetence, and if the members are not capable of expressing opinion they are not suitable persons to form a research committee of an important institution. We frame our remarks hypothetically, because, with such names as Unwin, Bryan Donkin, and Mair-Rumley on the title page, there can be no doubt that the power to afford guidance was present, and for this reason the decision to give only bare fact is the more to be regretted. The general conclusion to be drawn from the experiments, as quoted, is that "the expenditure of a quantity of steam in an efficient jacket produces a saving of a greater quantity in the cylinder." It does not follow from this that the jacket is always desirable, as the saving may be so small as not to justify the additional complication and increased outlay at first cost. That, however, is a matter upon which steam users must themselves decide upon a commercial basis, and is, of course, outside the province of the committee, but what would have been valued would have been some critical remarks giving guidance as to what goes to constitute the "efficient jacket," what fresh engineering practice is opened up by the use of the efficient-jacket, and under what conditions it may be most effectually applied.

The first series of experiments quoted were carried out by Mr. J. G. Mair-Rumley, of the firm of James Simpson and Co., of Pimlico, upon a compound jet condensing beam pumping-engine. The diameters of the cylinders are 29 inches and 47.5 inches, with strokes of 65.1 and 96 inches respectively. Only the body of each cylinder is jacketed, the steam being supplied direct from the boiler at a pressure of 49lbs. per square inch above atmosphere. Experiments were made both with and without steam in the jackets. The total feed water per indicated horse power per hour when the jackets were not in use was 18.20 lbs., with the jackets in use the corresponding figures were 16.64 lbs., thus showing a percentage of less steam used due to the jackets of 8.6. The quantity of jacket water condensed was 1.20 lbs. per I.H.P. per hour. The boiler pressure here was not high, 49.7 lbs. without and 49 lbs. with jackets

The number of revolutions were also low, 14 8 without jackets and 15 78 with jackets. This was evidently an engine which should pay for jacketing. We next come to an experiment of a different nature, carried out by Mr. Davey and Mr W B Bryan. The engine is triple expansion surface-condensing engine of the inverted direct acting marine type, and is placed in the Waltham Abbey pumping station of the East London Water Works. The cylinders were 18", 30 5", and 51" in diameter, by 36 inches stroke. There is a Meyer expansion valve to the high pressure cylinder, by means of which the speed of the engine was regulated during the experiment. The bodies and both ends of all three cylinders are steam-jacketed. The jacket steam of the high pressure cylinder is at full boiler pressure, but the other two cylinders have the pressure reduced to a little above that of their steam chests by means of reducing valves. Each cylinder is therefore jacketed with steam a little above its own initial pressure. Without the jackets in use the amount of feed water per I H P per hour was 17 22 lbs, and with the jackets in use 15 45 lbs, showing a percentage of less steam used owing to the jacket of 10 3. The total jacket water was 1 72 lbs per I H P per hour. The coal consumption is given in these experiments, being 2 09 lbs per I H P per hour without the jackets, and 1 79 lbs with. The amount of coal burnt is not, of course, necessarily a measure of economy of the engine, but possibly the steam-generating plant —which included an economizer—was practically constant in its duty during both trials, and if so the commercial gain by the use of the jacket is quite an appreciable quantity. The boiler pressure here was 130 lbs above atmosphere, the number of expansions without the jacket 22, and with the jacket 30. The revolutions were 23 per minute, so that the jacket had again a favourable chance.

The next series of experiments were carried out by Colonel English, Mr Davey, and Mr Bryan Donkin, and in these we reach a much higher piston speed, so that the results stand on a somewhat different footing in this respect to those before quoted. We have no positive knowledge of this engine beyond that given in the report, but it would be desirable to know something more of its working before accepting the very high percentage of gain in steam used—19 0 per cent —as that due to a steam jacket used on a good engine. The feed used per I H P per hour was 24 68 lbs without the jacket, and with the jacket in use the quantity was 20 lbs. The following are the particulars of this trial.—Horizontal surface condensing compound engine, with intermediate receiver cylinders, 18 and 32 ins by 48 ins stroke. The ends of the cylinders are not jacketed, and the receiver jacket was not in use during the experiment. The boiler pressure was 50 lbs, the revolutions 57 06 without jackets, and 63 62 with, the feed water supply as stated, and the jacket water condensed per I H P per hour 1 13 lbs. The coal used without jackets was 3 26 lbs per I H P per hour, and with jackets 2 66 lbs.

The last set of experiments we shall quote were made by Prof Unwin, upon the experimental engine[1] at the City and Guilds of London Central Institution, South Kensington. It is a two-cylinder horizontal surface condensing engine, and can be worked either simple or compound. The cylinders are 8 73 inch and 15 76 in diameter, by 22" stroke. The high pressure cylinder is fitted with Hartnell expansion gear, and the low pressure with Meyer expansion gear. Only the bodies and the back ends of the cylinders are covered. We will first give results of trials working the engine with the low pressure cylinder only. The pressure was 60 lbs above atmosphere, the jacket pressure being taken direct from the boiler. The revolutions without the jacket were 112 40, and with the jacket 101 73. The feed water per I H P per hour without the jacket was 32 14 lbs., and with the jacket 26 69 lbs. This gives a saving of 17 per cent working simple. It will be seen presently that when the engine was working compound, the saving was 7 3 per cent. The jacket-water per I H P. per hour was 1 88 lbs. We will now take the records of the compound trial. The boiler pressure was 66·73 lbs. without the cylinders, and 67 80 lbs with the jackets. The revolutions were 93 66 without the jacket, and 96·11 with. The feed water used per I H.P per hour was 21 06 lbs. without the jackets in use, and 19 52 lbs. with. The saving, as stated, made by the use of the jacket was therefore 7 3 per cent. The jacket water used per I H P per hour was 2·40 lbs. We regret we are not able to give all the interesting details which Prof Unwin includes in his instructive report, but for these we must refer our readers to the original paper.

Probably Prof Unwin's 7 3 per cent saving in steam used is a far better measure of the value of the jacket than the inflated promise of 19 per cent in Major English's trial. It should be remembered that the jacket is more effective in small than in large engines, the area of cylinder will be in a higher ratio to the contained steam in the former than in the latter case. The number of expansions in the South Kensington engine working without jackets was 7 23, and with jackets 9 29. The corresponding figures in the case of the Woolwich engine were 9 4 and 12 6. The boiler pressure with the Woolwich engine was, however, 16 to 17 lbs higher than in the other case. The revolutions were 57 06 and 63 62 respectively in the two trials at Woolwich, whilst at South Kensington they were 93 66 and 96 11. It would have been instructive if the committee had had the courage to attempt some balance of these figures, and then have endeavoured to account for the large difference which we believe would have remained still to be accounted for.

The next experiments quoted comprise a series made by Mr Bryan Donkin, junr, at the works of his firm at Bermondsey. Mr Donkin's labours in this field are well known, and engineering science is largely indebted to him for the contributions he has made to its lore. One most valuable feature in connection with these investigations is the means he has used to ascertain the temperature of the walls of the cylinder at various distances from the surface. In this lies the essence of the problem. If the Jackets Committee would give us minute and trustworthy information on this point we could evolve the rest from existing data. If we do not quote Donkin's figures in full it is partly because his experiments are not yet complete and partly because they have been dealt with more fully in "another place," namely, the Proceedings of a Society other than tha with which we are now dealing.[1] We may state, however, that in one case when the steam in the jacket space was 298° Fahr the cylinder walls averaged 290° Fahr, whilst at 0 06 in from the piston the temperature of the cylinder wall was 284° Fahr. These temperatures were ascertained by thermometers placed in holes drilled in the cylinder. Other instances are given, but the matter is far too interesting to deal with in a cursory manner, such as a report of this nature alone warrants. The difficulty that suggests itself is the fact that a thermometer itself has a very appreciable thickness, and the record will be but a mean of the temperature due to that thickness. It is possible that Mr Donkin gets over this difficulty in some way. Perhaps the thermo-couple as used by Le Chatelier might afford a solution, although this apparatus is not so useful for recording small differences at low temperatures, being rather adapted for such work as hot blast stoves and other metallurgical purposes. Mr Bryan Donkin's experiments are the most suggestive in the report, as might be anticipated. Trials were made with steam at various rates of expansion to determine the effects of the steam jacket on the speed of engine and temperature of the cylinder walls, and on superheating. The engine used was a small one (6" × 8"), but it was specially constructed and arranged for the work. We again repeat Mr. Donkin's investigations are well worthy of the study of all interested in these matters.

The report concludes with a valuable appendix in the shape of suggestions for the use of those desirous of experimenting in this field.

The discussion on this paper was of a protracted nature, but was not of a kind altogether worthy of the leading mechanical institution of the country. Mr Morrison, of Hartlepool, made the most weighty contribution amongst the speakers. He pointed out the difficulty of maintaining a good circulation of steam in the jacket—one of the most important points to which the designer of jacketed engines should turn his attention—and illustrated a simple method by which he had secured this end. His arrangement consisted of a series of diaphragms, by means of which the steam was made to take a devious course through the jacket. Mr. Schonheyder pointed out a mistake the committee had made in placing an air cock on the top of the jacket, when it was required to draw off air from the steam. Of course, this is one of those little slips which the wisest are apt to make, for it would be absurd to suppose such authorities as those en-

[1] This engine is stated in the report to have been fully illustrated and described in *Engineering* of November 16, 1888. The triple expansion engine at Waltham Abbey is also said to have been illustrated and described in the issue of August 8, 1891, of the same publication.

[1] See Proceedings Inst. Civil Engineers.

gaged did not know that air is heavier than steam. One might as well say one's grocer did not know sand from sugar.

The Jackets Committee has not yet concluded its labours, and another report will be forthcoming in due course. Mr. Aspinall has offered a locomotive for trial, and we heard that Mr. Yarrow will put a torpedo boat at the disposal of the committee, and has even promised to cast special cylinders for experimental purposes. The locomotive will afford an interesting field of research, running as it does so largely linked up. The torpedo boat experiments will be no less interesting, especially in view of the great number of revolutions the engines of these craft make in a given time.

On the second day of the meeting the paper by Mr. Walker of Bristol on the screw propeller. This paper gives the details of some experiments made by the author on a form of screw propeller invented by the late Mr. B. Dickinson. It would be in vain for us to attempt to condense this paper within the limits at our disposal. With regard to the merits of the Dickinson propeller we have nothing to say. It consists essentially of two narrow blades in place of one, and reminds us strongly of a Mangin propeller with one blade set somewhat back on the shaft. Mr. Walker contends that his researches prove the advantages of long narrow blades, but he did not appear to have converted the high authorities present, including Mr. Froude, Mr. Thorneycroft, and Mr. Barnaby—the three best-known names in connection with the subject—to his views. It is difficult to see wherein the value of the paper exists. Prof. Kennedy in the discussion stated that the generally received opinion as to the increase of the friction of the load was erroneous, and that the power absorbed in this way does not increase in the manner stated, a fact which he illustrated by means of a diagram. Mr. Thorneycroft pointed out that "life was not long enough" for the larger trials proposed by the author, but that he might decide one point if he would confine himself to models. Mr. Barnaby stated that a broad bladed propeller should not be a uniform pitch. Mr. Froude's speech was a lucid criticism of the author's paper, the speaker pointing out in a kindly but convincing manner that the conclusions arrived at by the author might be subject to revision. Mr. Dunell, whose previous experiments the author had quoted, added to the information given by putting forward some other experiments he had made upon screw propellers fitted to a torpedo boat, in this case the results being opposed to those claimed by the author, inasmuch as the shorter and broader blade had proved the more advantageous. Mr. Shield, of Liverpool, described a form of propeller which has been in use on the Mersey, and appears to offer some advantages. The blades are attached to the boss in two parts, and are joined in a loop at the top. According to Mr. Shield's statement, the arrangement gives great advantages in towing, and also increased steadiness in running. The latter we can accept as a fact, but the great increase in towing capacity seems almost too good to be accepted literally. Twenty five per cent. additional efficiency is a very large gain without further expenditure than an exchange of screws; but this is what the propeller in question is said to realize.

The meeting concluded with the usual votes of thanks.

INTERNATIONAL COMMITTEE OF WEIGHTS AND MEASURES

THE International Committee of Weights and Measures, which was established in consequence of the Metric Convention of 1873, has recently issued its fifteenth annual report to the Governments represented at that Convention.[1] The committee have also lately published the minutes of their proceedings (Procès-Verbaux des Séances. Paris, 1892. 1 vol. 8vo) at the annual meeting held at Paris in September, 1891. It appears to be hardly possible that the proceedings of the committee at their meeting which was held last month may be issued before next year, but from the above publications, as well as from a recent volume of their "Travaux et Mémoires," we gather that they continue to carry on their investigations with all despatch.

In their last report the committee deplore the death of their colleague, Jean Servais Stas, whose analyses of the platinum alloys have, together with those of St. Claire Deville and George Matthey, so largely helped forward the principal work of the committee; the metallurgical studies of Stas are indeed recognized as veritable models of classical research in this particular field.

The new instruments added to the Bureau at Sèvres during the last year include a normal barometer (le Baromètre Fuess) and manometer, originally verified for reference as an international standard in accordance with the decisions of the Meteorological Conferences, particularly that at Munich last year. The committee have also obtained a new apparatus for determining the normal thermometric "boiling point," or the temperature of 100° Centigrade, as it has been found that the form of apparatus used by Regnault was unreliable for this purpose. In the reading of the standard manometer it would appear that higher accuracy has been obtained by raising the surface of the mercury up to a fixed point, the image of the point in the mercury being observed at the same time by means of a microscope. The Wild-Pernet barometer has been re mounted, and the Bureau are now prepared to undertake the verification of any standard barometer.

The readings of all mercurial thermometers are given at the Bureau in terms of the hydrogen thermometer; and a 30 litre holder for methyl chloride, or liquid carbonic acid, has been made by Brigonnet and Navile. The low temperature experiments have been continued by M. Chappuis down to −75° Cent., and toluol and alcohol thermometers have been compared with the hydrogen thermometer. It has been found that "toluol" is more sensitive and reliable for low temperatures than alcohol.

We note that the meteorological work of the committee has largely developed itself, and that, as in geodetic research, the Bureau at Sèvres is now recognized as a central and international station of reference. Standard thermometers have been verified, for instance during 1892, for the Governments of Russia, France, and Roumania; for the Universities of Rome, St. Petersburg, and Odessa; for Owens College, Manchester; and for several recognized meteorological observatories. Great Britain has also been supplied by the committee with standard thermometers similar to those supplied to other contracting States.

Besides the standard metre and kilogramme already delivered to this country, the Bureau is undertaking the construction of a further standard metre for the Board of Trade, at a cost of 12,588 francs. The new standard appears to have been nearly two years in construction, but its verification is now promised this year.

There are twenty one different governments who have joined the Convention and who contribute annually towards the expenses of the Bureau (the annual budget of which is 75,000 francs), sums varying from 134 francs (Denmark) to 9482 francs (Germany): the annual contribution of Great Britain and Ireland for 1892 being stated at 4699 francs, or nearly £188; and that of the United States at 8471 francs.

At the instance of Dr. B. A. Gould the committee are now also undertaking an inquiry affecting measurement by light waves. By the use of the "Refractometer" Dr. Michelson found (*Philosophical Magazine*, April, 1891, and September, 1892) that accuracy of measurement by light waves may be increased to a high degree of accuracy. By the best spectroscopic instruments now in use it has been stated to be difficult to "resolve" lines as close together as the components of the yellow sodium lines, but that if the width of the lines themselves be less than their distances apart, then there is no limit to their accuracy of measurement by the "Refractometer." We shall look forward with interest to the publication of Dr. Michelson's further results, in the next volume of the "Travaux et Mémoires" of this committee.

The new instrument designed by M. Gustave Tresca, of the Conservatoire des Arts et Metiers at Paris, for the adjustment and polishing of the terminal surfaces of end measures of length appears also to be better than anything yet adopted in England.

The committee not only undertakes the verification of standards and instruments for the High Contracting Governments (who have the right to demand such verifications), but they also verify for any scientific authorities or persons. To those of our readers, therefore, who may desire to have standards or instruments verified by the committee, the following information may be useful:—

Applications for the verification of instruments should first be made to M. le Directeur du Bureau International (Dr. René-Benoît), au Pavillon de Breteuil, Sèvres, près de Paris.

[1] Rapport du Comité International. Gauthier-Villars. Paris. 1 Vol. 50 pp., 1892.

Standards may be sent to Sevres by post or railway (at the cost and risk of the owner), or still better, they may be delivered and removed from the Bureau by the owner or his agent. A certificate of verification will be given when the standards are ready for removal In any application to the director the denomination of the standard, or the description of the instrument, should be stated, and the nature and extent of the verification demanded

The committee will verify metric standards of length of one, two, three, and four metres, or subdivisions of the standard metre, if made in metal or some durable stone Line measures should have their graduations so fine as to be well observed with a microscopic power of sixty diameters, and end measures should have their terminal surfaces sufficiently adjusted and polished so as accurately to define the length of the bar Measures of mass may be made also of metal or some durable stone, but each must be in one piece without handles, grooves, or adjusting holes For thermometers and barometers special regulations are issued, which may be obtained at a small charge from MM Gauthier Villars, 55, Quai des Grand Augustins, Paris

The fees on verification of measures of length vary from 60 to 400 francs, according, of course, to the extent of the verification demanded, for metric weights from 20 to 120 francs, and for thermometers and barometers from 10 to 80 francs

What should be the true equivalent length of the yard measure in terms of the metre, may appear to some to be almost a trifling matter - because the measurement in dispute, or probable error of the equivalent at present adopted in this country, amounts only to 0 0008 inch It is, however, a fact that so small a difference as 0 0008 in this equivalent would not only be felt in scientific researches but also in practical work Messrs Comstock and Tittman, of the United Coast Survey, as well as Dr Peters, of Germany, and the Director of the International Committee, have found that the equivalent length of the metre (39 3708 inches) as ascertained by Kater and Arago, in 1818, is inaccurate, to the extent of 0 0008 inch, and that the true equivalent ought to be nearly 39 3700 inches This latter value will, we have no doubt, be ultimately recognized in scientific work

In the field of electrical measurements, we find that Dr Guillaume is continuing his investigations as to the measurement of temperature by electrical methods, and as to the variations of mercurial standards of resistance, a work originally begun at the Bureau, by Dr Benoît, in connection with the standard ohm It would not appear that mercurial thermometers can be superseded for ordinary measurements of temperature, but that measurement by resistances may afford useful results in determining the temperature of a given mass or space, as the whole length of a column of mercury Dr Guillaume gives an account of his work on mercurial standards in the Procès-Verbaux recently issued (page 183)

During the past year Commandant Defforges, of the Geographical service of the French army, has been undertaking at the Bureau an inquiry into the effect of the force of gravity at the latitude of Breteuil, by means of a seconds pendulum and apparatus constructed by Brunner M Defforges found that at Breteuil (longitude east of Paris 0° 131, latitude north 54 260, and altitude 70 4 metres) $G = 9\ 80991$ m

We cannot conclude this glance at the recent work of the International Committee without expressing an opinion that the scientific success of their work and the accuracy of its record, owe much to the energy and watchful care of the new president, Dr Foerster, and the secretary of the committee, Dr. A. Hirsch.

NOTES ON SOME ANCIENT DYES[1]

THE fragments of ancient dyed fabrics which I have examined I owe to the kindness of Mr R D Darbishire They are specimens from a lot found by Mr. Flinders Petrie in a tomb at Garob, Lower Egypt, supposed to date from 400–500 A D They were used apparently for filling the mummy cases where required, not strictly speaking as grave clothes My object in examining them was to ascertain, if possible, what were the materials employed in producing the various colours seen on them The fabrics examined consisted almost entirely of wool Here and there in the warp of some of the specimens were threads, conspicuous for difference in colour, consisting of linen The following colours could be distinguished:—blue, yellow, green, red, maroon, purple or claret, black I will take them in the order named

Blue —The colour of the fabric was a dull medium blue On treatment with hot caustic lye a great part of the wool dissolved The residue, which was dark blue, having been filtered off, washed and dried, was treated with boiling aniline, to which it communicated a bright blue colour The blue solution having been filtered boiling, deposited on cooling a quantity of blue crystalline scales, which, after being filtered off, washed with alcohol and dried, were found to consist of indigo blue On being treated in a tube they gave a sublimate of regular crystals, blue by transmitted, copper-coloured by reflected, light, they dissolved in concentrated sulphuric acid, giving a blue solution, and the solution in aniline showed the absorption spectrum of indigo blue It is evident, therefore, that indigo in some form or other was the material used in dyeing this colour

Yellow —The colour of the patches dyed yellow was so evidently faded, and showed so little intensity, as to make it very uncertain whether analysis would lead to any precise result, the examination was therefore omitted

Green —Of the material dyed this colour, I had but a small quantity, but it was sufficient to allow of some conclusion regarding the means whereby the colour was produced On being treated for some days with dilute hydrochloric acid it imparted to the latter a deep yellow colour The portion left by the acid, after being washed and dried, yielded indigo blue on treatment with boiling aniline It is probable, therefore, that the colour was produced by first dyeing the fabric with indigo, then treating with some mordant, such as alum, and, lastly, dyeing with some yellow colouring matter, most likely of vegetable origin With the small quantity of material at my disposal, I found it impossible to ascertain the nature of the yellow colouring matter employed

Red —This was the most pronounced, and at the same time the most interesting, of the colours examined The colour of the fabric was a full deep red It might be called a Turkey red, the dye, in fact, proved on examination to be a kind of Turkey red as having the characteristic properties of that dye

On being burnt, the fabric left a considerable quantity of ash, consisting of calcium sulphate, alumina, aluminium phosphate, ferric oxide, and silica A large portion of this ash no doubt represents the mordant employed in producing the colour On treatment with hot dilute hydrochloric acid, the fabric lost its red colour and became yellow After removal of the acid by washing with water, and pressing between blotting paper, treatment with boiling alcohol deprived the wool of the greater part of the yellow colour, a faint tinge only being left. The deep yellow alcoholic liquid obtained left on evaporation a reddish-brown amorphous residue This, on being treated with a boiling solution of alum, dissolved in part, yielding a pink fluorescent liquid, which had exactly the same colour, and showed precisely the same absorption bands as a solution of purpurin from madder in alum liquor On adding hydrochloric acid to the pink solution and heating, the colouring matter was precipitated in orange-coloured flocks, the liquid becoming almost colourless The flocks after being filtered off and washed with water dissolved easily in boiling alcohol, yielding a yellow solution, which, on spontaneous evaporation, left a quantity of dark yellow needles arranged in rosettes These needles dissolved in caustic alkali, giving a cherry red solution, which showed the absorption bands of purpurin. The solution, on exposure to air and light, became colourless

Some of the precipitated colouring matter, on being employed in the usual way for dyeing a bit of calico to which various mordants had been applied, yielded colours exactly like those obtained with purpurin from madder, *i e*, the alumina mordant gave a bright red, the iron mordant dull purple to black tints The matter left undissolved, after repeated treatment with boiling alum liquor, was still highly coloured. It dissolved easily in alcohol, the solution leaving on evaporation a brown amorphous residue, which remained soft even after long standing. This residue consisted for the most part of fatty matter, but it also contained some colouring matter insoluble in alum liquor. That this colouring matter was alizarin seemed probable, since the colour which the mixture imparted to alka-

[1] Reprinted from "Memoirs and Proceedings of the Manchester Literary and Philosophical Society," 1891-92 (Fourth Series, vol 5, No. 2).

line lye resembled that of an alkaline solution of impure alizarin

These experiments lead to the conclusion that the red colour of the fabric was produced by dyeing with some kind of madder, either wild or cultivated, the fabric having been previously treated with a mixed aluminous and ferric mordant, and then probably oiled—that it was, in fact really a kind of Turkey red

Maroon —The dull chestnut colour of this fabric presented a striking contrast to the bright red of the preceding Its constitution was, however, similar Having treated it in the same way as the other, I found that the colouring matter must have been derived from madder, fatty matter was also present, but the mordant contained a larger proportion of ferric oxide, a fact which sufficiently explains the brown tint of the dyed fabric

Purple —The fabric in which this colour was seen was made up of a pale yellow warp, and a weft of a dull purple or claret colour The latter colour was found to be due to an intimate mixture of red and blue, for the threads, on examination under the microscope, were seen to consist partly of red, partly of blue fibres, the former predominating The two sets of fibres had, of course, been mixed before spinning The blue fibres were certainly dyed with indigo, the red probably with madder

Black —The colour of the black fabric, like that of the green, was a compound of two colours, one overlying the other Under the microscope the individual threads appeared grey On treatment with a mixture of alcohol and hydrochloric acid they changed colour, a yellow liquid being obtained, while the fabric itself now appeared blue, and after washing and drying yielded indigo by appropriate treatment The yellow alcoholic liquid was found to contain purpurin. The colour may be supposed to have been produced in the following manner —The woollen fabric having first been dyed blue was mordanted, to use a modern phrase, and then dyed with madder, the two colours together producing the effect of black

EDWARD SCHUNCK

SCIENTIFIC SERIALS

IN the *Botanical Gazette* for July, August, and September, there are several papers of general interest Mr G A Rex presents a further contribution to our knowledge of the Myxomycetes in an account of the genus *Lindbladia* —Mr D T McDougal gives a detailed account of the morphology and anatomy of the tendrils of *Passiflora cærulea* —Mr M B Thomas describes and figures an apparatus for determining the periodicity of root pressure in plants —Mr C L Holtzman has a short paper on the Apical growth of the stem and the development of the sporange in *Botrychium virginianum*, his observations favouring the view that the Ophioglossaceæ are a more primitive form than the typical Filices —Mr A F. Foerste continues his observations on the Relation of autumn to spring blossoming plants —Mr Charles Robertson gives a further instalment of his series of papers on Flowers and insects —A brief report is given of the botanical papers read at the recent meeting of the American Association for the Advancement of Science

IN the *Journal of Botany* for September and October, no less than four new species are added to the British flora and to science—*Hieracium hibernicum*, *H duriceps*, and *H Breadalbanense*, by Mr F J Hanbury, and *Ranunculus petiolaris* (sect. Flammula) by Rev E S Marshall —Rev W Moyle Rogers continues his Essay at a key to British Rubi, Mr E G Baker his Synopsis of genera and species of Malveæ, and Mr W. A. Clark his First Records of British Flowering Plants

Bulletin of the New York Mathematical Society Vol ii No. 1, October, 1892. (New York)—Prof Cajori opens this number with an interesting note on the evolution of criteria of convergence (pp 1–10), in which he discusses some special and general criteria furnished in the writings of Gauss, Cauchy, Abel, DeMorgan, Bertrand, Kummer, and others, and notices specially the remarkable advance made by Pringsheim (*Math Ann.* vol. xxxv.).—Dr. A Martin calls attention (pp. 10–11) to a slip in Ball's "Short History of Mathematics" (p. 102), the probable origin of which is accounted for by Mr Ball.—There is a slight review of Chapman's "Elementary Course in the Theory of Equations" (pp 11–12), and the rest of the issue is taken up with the usual list of new publications and notes In these last Dr Martin points out a curious error in the Royal Society "Catalogue of Scientific Papers," vol ix (1874–1883), where, of the papers accredited, on p 790, to Ezekiel Brown Elliott, Nos 5 11, 14–17 should be assigned to Mr Edwin Bailey Elliott, of Oxford, and not to the late Mr Ezekiel Brown Elliott, of America, to whom Nos 4, 12, 13 are rightly attributed

IN the *Bullettino* of the Botanical Society of Italy, we find in addition to papers of more local interest, a further communication from Sig Macchiati on the Cultivation of diatoms, in which he states that the presence of infusoria and of diatoms in the water is mutually beneficial to one another, while the most destructive enemies of the latter are bacteria —A paper by Sig Piccioli on the Biological relations between plants and snails, is chiefly devoted to the protective contrivances found in the former against the attacks of the latter, the most important of which are of a chemical nature—tannin, latex, oleiferous glands, and poisonous salts such as calcium oxalate mechanical means of protection, such as hairs and a comparatively thick cuticle, play a subordinate part —In a further communication by Prof Arcangeli on the Cultivation of *Cynomorium coccineum*, he states that he does not find such an intimate parasitism with its host as is the case with the Rafflesiaceæ and the Balanophoraceæ.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, October 24.—M de Lacaze Duthiers in the chair —Researches on the fixation of atmospheric nitrogen by microbes, by M Berthelot The investigation was made in order to elucidate the mechanism of the fixation of atmospheric nitrogen It appears that the presence of green vegetable material is not essential to the process The colourless bacteria are able to absorb nitrogen when supplied with humic acid only as nutriment The assimilation takes place more readily with natural than with artificial humic acid, probably because the former contains more nitrogen. In experiments with hermetically sealed cultivations it was found that the gain of nitrogen by the organic material under cultivation was 6 or 9 per cent in excess of that supplied by the humic acid, the difference being derived from the enclosed air With an occasional stream of dust laden air this was brought up to 30 per cent —Coloured photographs of the spectrum on albumen and bichromated gelatine, by M G Lippmann Albumenized and gelatinized plates soaked in bichromate of potash may be employed for photographing in colours They are used like silver-salt plates, being placed so that the mercury is in contact with the film The colours will appear immediately after immersion in water, which develops and also fixes the image It disappears on drying, but reappears as soon as the plate is soaked The colours are very brilliant, and visible at all angles Those of gelatine plates are brought out by simple breathing The theory is analogous to that of silver plates, the maxima and minima of interference producing hygroscopic and non hygroscopic layers with varying refractive indices —The irrigation canals of the Rhone, by M Chambrelent —A new apparatus, the schiseophone, serving the purpose of exploring the internal structure of metallic masses by means of an electro mechanical process, by M de Place. The apparatus consists of a microphone and an induction sonometer To the microphone is attached a rod of hard steel, kept oscillating once or twice per second, and striking each time against the casting or other mass of metal under investigation The sonometer, consisting of two coils movable towards or away from each other along a divided scale, with a telephone connected with one of the coils, is placed in another room, and joined by wires to the microphone. The coils being so adjusted that the tapping is scarcely perceptible at the sonometer, the casting is moved so as to expose various portions to the impacts. If the thickness be uniform, any flaw or fissure will be at once indicated by a change in the sound —Observations of the comet Barnard (D 1892), made at the Paris Observatory, by M G Bigourdan

—Elements of the comet Barnard, of October 12, 1892, by M. L. Schulhof.—On the algebraic integrals of the differential equation of the first order, by M. L. Autonne.—On centres of geodesic curvature, by M. Th. Caronnet.—On Pfaff's problem, by M. A. J. Stodolkievitz.—Sunspots and magnetic disturbances in 1892, by M. Ricco.—On considerations of homogeneity in physics, reply to M. Clavenad, by M. Vaschy.—Verification of parallelism of optic axes in uniaxial crystalline plates, by M. Bernard Brunhes.—On a photoptometric photometer, for the measurement of feeble illuminations, by M. Charles Henry. This is based upon the constancy of the phosphorescent sulphide of zinc. Its law of loss of brilliance being determined, it may be used for measuring very feeble illuminations, such as distant artificial light or the general luminosity of the sky due to the stars. The decrease of light after the first 900 seconds being given by $i^{0.5}(t - 18.5) = \text{const.}$, it is easy to calculate the luminosity at any instant. In the instrument in question there are two screens of ground glass, one of which is illuminated by the phosphorescent sulphide, brought to its maximum glow at a certain time by burning magnesium ribbon, the other exposed to the source of light. It is then only necessary to wait till both the screens are equally illuminated, and to note the time.—On the dissociation of chrome alum, by MM. H. Baubigny and E. Pechard.—On the temperatures of maximum density of aqueous solutions, by M. L. de Coppet.—On some double salts of quinine, by M. E. Grimaux.—On the thermal value of the three functions of orthophosphoric acid, and on its constitution, by M. de Forcrand.—Preparation and properties of fibroine, by M. Leo Vignon.—Regeneration of the so-called sporangial form in the diatoms, by M. P. Miquel.—On the hematozoaria of cold-blooded vertebrates, by M. Alphonse Labbé.—Influence of coloured light on the development of animals, by M. E. Yung.—On the mode of fixation of the hexapod parasitic larvæ of the acarians, by M. S. Jourdain.—The cavern of Brassempouy, by M. Édouard Piette.—Discovery of a skeleton of *Elephas meridionalis* in the basaltic ashes of the volcano of Seneze, by M. Marcellin Boule.—Vegetable prints of the Dover boring, by M. R. Zeiller.

Berlin

Meteorological Society, October 11.—Prof. von Bezold, president, in the chair.—Dr. Berson reported on an interesting relationship which he had discovered between insolation and temperature. Since it has not yet been possible to determine accurately the absorption due to the atmosphere, the speaker had calculated the insolation at the external limit of the atmosphere, which admits of rigid mathematical treatment, both for the whole year and for the months of January and July. The mean of insolation for the whole year was found to lie at the thirtieth degrees of northerly and southerly latitude, so that the zone between these parallels, or about 60 per cent. of the whole external surface, receives more insolation than the mean, whereas the two polar caps, or the remaining 40 per cent., receive less. A similar calculation of the annual temperature gave the mean as at latitude 38° N. and 35° S., giving as before 60 per cent. of the surface with the temperature above the mean, and 40 per cent. below. In January 61.35 per cent. of the surface experienced an insolation above the mean and 60 per cent. a temperature above the mean, while in July the percentages were respectively 61.37 and 61.33.—Dr. Zenker gave a short account of a research on the relationship between temperature and insolation on the earth's surface. He had accurately calculated the relationship both for regions comprising land only and water only, and arrived at some interesting conclusions as to the theoretical temperatures at various latitudes of continents and oceans.

Physical Society, October 21.—Prof. Kundt, president, in the chair.—Dr. Jager gave an account of the measurements he had made, in conjunction with Dr. Kreischgauer, of the temperature-coefficient of electric conductivity of mercury. Dr. Arons demonstrated an arc light between mercurial electrodes in vacuo. It yielded a dazzling white light, which was steady at the anode but flickered and jumped at the cathode. Its intensity approximated to that of an ordinary carbon arc-light. The heat given off by it was but slight so that the tube could be held in the hand; the temperature was highest at the cathode. Attempts were made to determine the resistance of the arc, but without result. It was found by the use of a telephone that the current is discontinuous. A spectroscopic investigation of the light revealed a lime-spectrum showing very brilliantly a yellow, a green, and a blue line. In addition to the ordinary lines due to mercury some twenty new lines were observed. No satisfactory results were obtained by using amalgams instead of mercury, with the one exception of sodium amalgam. It is proposed to make further experiments with fluid amalgams of sodium and potassium.

EXPERIMENTAL BIOLOGY

Experimental Evolution By Henry de Varigny, D Sc. (London Macmillan, 1892)

DR HENRY DE VARIGNY has enriched the literature of biology by publishing in the "Nature Series" the lectures on "Experimental Evolution" delivered by him in 1891 to the Summer School of Art and Science in Edinburgh. This school, as is well known, has been doing good work on Extension lines in Edinburgh, and Prof Geddes is to be congratulated on having secured the co-operation of so able a biologist and so lucid an exponent of the special aspects of biology with which he has identified himself as M de Varigny The lectures are well worthy of publication, for they contain a rich, well-ordered, and, for the most part, well sifted body of facts collected from many sources, and especially from the publications of French naturalists But the author is more than a collector of facts recorded by other workers, he is himself a worker in this special field of biological science And some of the most valuable of the observations contained in the work are the result of his own careful and exact investigations

Experimental biology is still in its infancy It is true that our domesticated animals and plants are the result of much experimental work in the past, but the experiments were not planned with the object of explaining organic nature, and were therefore not biological in their aim There is pressing need at the present time for experiments with such definite scientific aim, for experiments, that is to say, carried out with the express object of testing the truth of biological principles And that this work be well done there is pressing need for organization We have only to look at the results which have been reached by well-planned and well-directed marine stations in extending our biological knowledge, faunal, morphological, and embryological, to see what may be done by organization of research. What Dr de Varigny eloquently pleads for, and what our own countryman, Dr Romanes, is also pleading for, is an experimental institute, well planned and adequately supported, the purpose of which shall be to carry out extensive experiments for testing evolution hypotheses in all their bearings

"It appears to me," says Dr. de Varigny, "that this institution should comprise the following essential elements :—Rather extensive grounds, a farm with men experienced in breeding, agriculture, and horticulture, some greenhouses, and a laboratory with the common appliances of chemistry, physiology, and histology Of course this must be located in the country. It is very important to have experienced farm hands, and a good chemist and histologist are necessary in the staff of the institution. As to the general management, it seems advisable to have a director with a board of competent men, whose functions would be to decide, after careful investigation and exchange of views, what are the fundamental experiments to be performed These experiments, when once decided upon, should be pursued during a long period of years, and nothing should be altered in their execution unless considered advisable by the board, or unless the experiment should be found useless, or devoid of chance of success The main thing should be to provide for the duration of the experiment, whether the originators were living or dead, and to follow it out for a long time Time is an indispensable element in such investigations, and experiments of this sort will surely exceed the normal duration of human lifetime"

A special branch of the work of such an institute should be experimental investigations in comparative psychology Of this there is nowadays some need Speaking of the transmission of acquired characters, Dr de Varigny says, "Psychology affords similar instances A kitten which has never seen a dog is afraid from the first moment it perceives one, young birds of many species instinctively fear the hawk and other birds of prey, while remaining unaffected by the presence of other birds Are not these psychological 'attitudes' due to environment (acting on the *mens* of ancestors) which have been transmitted by inheritance, are these not *acquired characters?*" From observations of my own I am prepared to say that it is by no means universally true that a kitten which has never seen a dog is afraid from the first moment it perceives one Mr Spalding does indeed describe how the smell of his hand with which he had been fondling a dog set four blind kittens puffing and spitting in a most comical fashion But a careful observer, Mr Mann Jones, writes to me that a young kitten with which he experimented "took eight days to connect the smell or odour of his hand with the thing—dog" And my own observations are confirmatory of those of Mr Mann Jones. Mr Hudson, in a very interesting chapter of the "Naturalist in La Plata," gives observations which tend to show that young birds afford little evidence of instinctive fear of particular enemies, and my own experiments with young chicks lead me to believe that they have no instinctive knowledge of the things of this world Any unusual and sharp sound (*e g*, a chord on the violin), any large approaching object (*e g.*, a ball rolled towards them), causes alarm There is no evidence of instinctive particularisation of alarming objects Such observations lead me to look with suspicion on any arguments for the transmission of acquired characters based on supposed instinctive knowledge of things And they show the need of further research in comparative psychology such as could be carried out at the Institute of Experimental Biology

It may be said that the central hypothesis of modern evolution, that of natural selection, stands in no need of experimental verification. But it will presumably be admitted, even by those who are firm in their belief, among whom I count myself, that further experimental support will be of the utmost value There are many who assume a sceptical attitude, and who say—We grant the inexorable logic of your conclusions if your premisses be established More individuals are born than can or do survive, the devil devours the hindmost, and a beneficent selection rewards the survivors with the privilege of procreation. hence, progress towards increased adaptation A very pretty piece of logic But now, they say, show us the devil at work. We pretend to no particular knowledge

of these matters, but we are quite ready to be convinced by proven facts. Prove to us this devil's work, and we acquiesce in your conclusion But do not put us off with a logical "must be," the recognized symbol of an assumption Do not tell us that since a hundred were born and only two survive, the ninety-eight must be in some way and for some reason unfit This is just the very fact of which we require definite and indubitable evidence.

Now what solid and unimpeachable body of evidence have we wherewith to conclusively refute this scepticism? If animals or plants removed to a new environment assume a new habit, in how many cases is it clearly *proved* that this is due to the elimination of all those who failed to vary in the direction of this habit? It behoves us to be careful that the very strength of the natural selection hypothesis be not a source of weakness, by leading us to neglect the duty of experimental verification That there should be a central institute or institutes for the purpose of such experimental verification, is what Dr de Varigny and Dr Romanes are pleading for It would produce a salutary organization of research, for the institute would have carefully selected correspondents in all parts of the world who would carry out their experiments in concert It would bring scattered energies to a focus It would by its journal show individual workers where research is specially needed It is bound to come sooner or later We hope to see it an established fact before the close of the present century.

C LL M

BRITISH FUNGUS FLORA

British Fungus-Flora, a Classified Text-Book of Mycology By George Massee In 3 vols Vol. I (London and New York George Bell and Sons, 1892)

IT was in 1836 that Berkeley published his "British Fungi" as a part of Hooker's "British Flora," and for about a quarter of a century this was the standard work In 1860 appeared Berkeley's "Outlines of British Fungology," which from the first was disappointing, inasmuch as it was only a barren catalogue for all except the large and conspicuous species, and even the latter were so compressed in description, by the exigencies of confining the book within narrow and definite limits, that it did not wholly supersede the use of the old "British Fungi" In 1871 an effort was made to repair the error by the publication of Cooke's "Handbook of British Fungi," which brought the whole subject up to date, and gave a new impetus to British mycology On account of the considerable acquisition of species, new to the British flora, it was deemed fitting in 1871 to produce a new work which should include these additions, and then Stevenson's "British Fungi" appeared. This new work only included the "Hymenomycetes," or, in effect, part of the first volume of Cooke's "Handbook," leaving all the rest untouched. In order to remedy this deficiency in part, Cooke's "Myxomycetes" was issued in 1877, and Phillips' "Manual of British Discomycetes" in 1887. Meanwhile a second edition of a portion of Cooke's "Handbook" was being issued as a supplement to "Grevillea," but confined exclusively to the *Agaricini*. With the exception of Plowright's "British Uredineæ" published in 1889, all the rest of the orders contained in the "Handbook" remained as they were in 1871 The unrevised portions included the *Pyrenomycetes*, or Sphæriaceous fungi, the *Sphæropsideæ*, or imperfect Pyrenomycetes, and the *Hyphomycetes*, or moulds. Hence the announcement of a complete work which should include *all* the British fungi, of whatever denomination, brought up to date, did not come as a surprise

The volume before us consists of 430 pages, and professes to be the first of three volumes, which are to contain the whole "British Fungus Flora" in full, and upon the same plan as this first volume We have heard of wonderful feats of "strong men," but these will be nothing in comparison to the feat which is ostensibly promised on the title-page, *when* it is accomplished In our simplicity we should have calculated *six* volumes as nearer the minimum If the result proves to be *less*, we shall be content to bear the odium of a false prophet We may premise that the author who has undertaken the preseut work is eminently fitted to carry it out successfully, inasmuch as he is a practical field naturalist, with independent views, and by no means afraid of hard work

To return to the volume in question, we must recognize clearness of typography, and distinctness in the isolation of species, which will facilitate reference and increase its practical utility. The illustrations are rather rough outlines, but quite sufficient for practical purposes, and will exhibit the distinctions between the several genera as far as illustrations can do it Of the systematic arrangement we are not prepared to speak so highly, but perhaps some may consider this a matter of detail The contents may be summarized thus, in the order of their appearance The *Gastromycetes*, or puff-ball fungi, commencing with the subterranean species, followed by the *Sclerodermeæ* and the *Nidularieæ*, then the *Lycoperdeæ*, concluding with the *Phalloideæ* These are succeeded by the *Hymenomycetes*, in like manner inverted, commencing with the *Tremellineæ*, and backwards through the other families to the *Agaricini*, which are commenced in the last 120 pages, but not half completed We imagine that half another volume will be required to complete the *Basidiomycetes*

Under ordinary circumstances, when we take up a flora, we are accustomed to meet with the adoption of either one of two methods The one consists of a regular sequence, from what the author regards as the highest developments in his congeries to the lowest, the other an equally regular sequence from the lowest to the highest This is conventional, but the present book is not conventional. In one sense there undoubtedly is a regular sequence from the lowest forms to the highest in the *Basidiomycetes*, which this volume contains; but we must not infer that Mr. Massee regards the *Basidiomycetes* as the lowest order of Fungi, or that he commences with the simplest organisms, proceeding upwards by regular gradations to the most complex, when he starts with the *Gastromycetes*. Undoubtedly our author has not made a special study of the puff balls in order to degrade them to the lowest rank. Hence we can only arrive at one conclusion, and that is, that such portions of the work have now been printed as were ready for the press, and no conclusions are to be drawn from the sequence adopted as a convenience, as if it were adopted by premeditation

Continental mycologists have now for some time accepted the genera of the *Agaricini* as defined by Fries, with the exception of the large genus *Agaricus*, which Fries himself subdivided into numerous smaller groups as subgenera, but they have elevated all these smaller groups to the rank of genera, and placed them upon an equality with the other veritable genera of *Agaricini*. Against this metamorphosis we feel bound to contend, on the ground that the distinctions, although sufficient for the subdivision of a genus, are not of generic value, and that the genera so constituted are unnecessary, and of unequal value, with the old genera beside which they are placed. For instance, *Amanitopsis* differs only from *Amanitæ* in the absence of a ring, and *Annellaria* differs only from *Panæolus* in the presence of a ring. Let any one of practice and experience compare these pseudo-genera with *Coprinus*, *Cantharellus*, or *Schizophyllum*, and judge of what we say. For the first time these pseudo-genera now find a place in a British flora, and, although not of overwhelming importance, we cannot permit them to pass without protest.

Spore measurements are a recent addition to the diagnoses of *Hymenomycetes*, and, although we contend that they should be employed with caution and discrimination, it is very satisfactory that so much attention should have been given to them in this work. Not only does the spore vary in size in a given species in different seasons, but at different periods in the same year. This is certainly true in some species which have been tested, and should lead us to accept spore measurements as approximate rather than absolute.

In conclusion, we are bound to remark that this is a student's book, written with a full appreciation of the wants of a student, and giving all the information which a student might require. In all cases, whether under families, genera, or species, will be found just the details which the novice will be most anxious to obtain, and, although the study of these interesting but rather difficult plants has been of late somewhat upon the decline, we doubt not that it will revive and prosper by the aid of the new "British Fungus Flora," which will become the "text-book of British mycology." M. C. C.

SOUTH AFRICAN SHELLS

Marine Shells of South Africa. A Catalogue of all the Known Species, with References to Figures in Various Works, Descriptions of New Species, and Figures of such as are new, little known, or hitherto unfigured. By G. B. Sowerby, F.L.S., F.Z.S. Pp. 89, 5 pls. [drawn by the author]. (London, 1892.)

SINCE 1848, when Krauss published his well-known work, entitled "Die Sudafrikanischen Mollusken," no such list as the one before us dealing with the Molluscan Fauna of this interesting and important marine province has appeared.

Krauss, who included the non-marine forms of the South African region in his work, recorded 403 marine species, of which 213 were considered to be peculiar to the province. Many other species have been subsequently cited or described as coming from that quarter, notably by E. von Martens and by our present author.

Conchologists undoubtedly owe much to Mr. Sowerby for thus bringing together within the small compass of this single volume, the scope and aim of which are sufficiently indicated in its title, the scattered records of the various species as known to him; but they will equally regret that the author did not include the whole molluscan fauna instead of confining himself to the testaceous forms, and thereby raise the work from the level of a mere shell-collector's catalogue to the rank of a work of reference of real scientific value.

Mr. Sowerby enumerates 740 species, and estimates that 323 of these are confined to South Africa, whilst 67 also occur in European seas, and 340 have been found on other coasts. Unfortunately, it is our disagreeable duty to point out that this record does not include "all the known species," and hence is not what the author fully intended it to be, viz., "as complete as possible." An important paper by Von Martens[1] appears to have been overlooked, for there are about thirty species named in it, including some which were then new, not mentioned by Mr. Sowerby. Still more remarkable is the omission of the new forms described by Mr. Watson in his report upon the Scaphopoda and Gastropoda, obtained during the voyage of the *Challenger*. Davidson's "Monograph of recent Brachiopoda," had it been more closely scanned, would have yielded not only two species reputed to have come from the Cape, but also *Terebratulina Davidsoni*, King, the type specimens of which, dredged on the Agulhas Bank, were passed on to their describer by Mr. G. B. Sowerby (the elder, we presume) in 1871.

A number of species have been recorded by Mr. E. A. Smith in an appendix to a "Report on the Marine Molluscan Fauna of the Island of St. Helena,"[2] as found there on what is locally known as "Sea-horn." This substance appears to consist of portions of a large species of Tangle, probably *Echlonia buccinalis*, which occurs at the Cape, whence it drifts to St. Helena. Some allusion should have been made to these forms. Hints might also have been gleaned from the same report, which deserves to be more widely known than seemingly it is, of undoubted South African species whose names do not appear in Mr. Sowerby's catalogue.

The presence of a good index, while it obviates the necessity, does not abolish the desirability of a good classification, and, in the present state of our knowledge in matters conchological, that of Woodward's Manual is hardly up to date; it is somewhat late in the day to find *Dentalium* still in its old place in the Gastropoda.

Some few changes in nomenclature are made in deference to the law of priority, and these are set forth at the end of the preface. Amongst them is *Ovula*, Bruguière, 1789 = *Ovulum*, Sowerby, &c., though, according to some, *Ovula* is itself a synonym for *Amphiperas*, Gronovius, 1781; *Calliostoma* is erroneously attributed to Bruguière instead of Swainson.

There are also some oversights in the text, as, for instance, "*Columbella cerealis*, Menke (Buccinum), Krauss = *C. Kraussii*, Sowerby," where, since Menke's name was given merely in MS., Sowerby's name stands, having four years' priority over Krauss's; *Triforis* is treated as though of the masculine gender; whilst the references to "figures in various works" require careful checking.

[1] "Ueber einige südafrikanische Mollusken nach der Sammlung von Dr. G. Fritsch." Jahrb. Deutsch. Malak. Gesell. 1874, pp. 119–146.

[2] Proc. Zool. Soc. 1890, pp. 247–317.

As regards the figures that accompany the work itself, it is a matter for regret that they cannot be commended. Few objects are more difficult to draw or require more skill in their delineation than do the shells of mollusca, and the amateur is rarely able to do them justice The want of finish in the present instance is all the more noticeable from the contrast they afford to the rest of the "get up" of the work, which is admirable

These shortcomings are not thus dwelt on in any captious spirit, but are pointed out in the friendly hope that a future edition of the work may shortly be forthcoming, in which the defects of the present one, compiled under great difficulties and at much disadvantage, may be made good and a really complete catalogue result

(BV)[2].

OUR BOOK SHELF

The Framework of Chemistry Part I By W M Williams, M A. (London George Bell and Sons, 1892)

THIS is the first part of a book which has been specially written as a supplement to the oral lessons and experimental demonstrations given by a teacher It is intended to contain nothing but what is absolutely necessary to give definite and precise impressions regarding the salient points of the lessons, all details relating to laboratory manipulation being omitted The more important introductory facts, divested of theoretical considerations, are first discussed, then come "atoms and molecules," treated in an elementary fashion and leading the way to the explanation of the use of symbols and formulæ

How the system adopted by the author will work out can only be ascertained when the other parts are to hand So far as the information in the present volume goes, it is to a great extent useful and clearly stated

Objection may be taken to the classification of solutions as mechanical and chemical, for, were it for no other reason, it is still a disputed point whether any solution may be considered a mixture

The concise style of the book lends itself to incomplete statements For instance, to say that one of the oxides of carbon "contains exactly twice as much oxygen as the other," is hardly accurate, a constant quantity of carbon is essential to the accurate conception of the facts The most serious blunder made by the author lies in the confusion of force and energy This is manifest in statements involving the conversion of "chemical force" into an "equivalent amount of heat" or of "electrical force," and culminates in the assertion that "Force, like matter, cannot be destroyed."

The Beauties of Nature, and the Wonders of the World we Live In By the Right Hon Sir John Lubbock, Bart. M P, F R S (London Macmillan and Co, 1892.)

SO many writers of the present day adopt a pessimistic tone that a pleasant impression is always produced by Sir John Lubbock's genial and imperturbable optimism In the present volume he undertakes to show how many sources of interest men might find in the world around them, if they would only take the trouble to train themselves to appreciate the scientific significance of ordinary facts. He begins with a study of animal life, and has much that is fresh and suggestive to say about various aspects of the subject. Then there are chapters on plant life, woods and fields, mountains, water, rivers and lakes, the sea, and the starry heavens The volume is written in the clear, frank style with which all readers of Sir John Lubbock's books are familiar, and it ought to do much to foster among the class to which he appeals habits of careful and exact observation His readers have the satisfaction of knowing that of the many things they may learn from him none will afterwards have to be unlearned

Algebra for Beginners By H S Hall and S R Knight (London Macmillan & Co 1892)

THIS work is intended as an "easy introduction" to the author's "Elementary Algebra for Schools," and, besides being treated on lines similar to those of the last-mentioned book, is published in a cheaper form The idea throughout seems to have been to present the beginner with the practical side of the subject, and with this intention the examples are made as interesting as such examples can be The usual sequence has not here been strictly adhered to, but a beginner will find that he will still be able to reach the "as far as quadratic equations" limit It is needless to say that the explanations are stated in clear and simple language, while the examples are all new That this book will be widely used is undoubted, for it will form an excellent forerunner to the more advanced one referred to above

Introduction to Physiological Psychology By Dr. Theodor Ziehen Translated by C C van Liew and Dr Otto Beyer (London Swan Sonnenschein and Co 1892)

IN reviewing the book of which this is a translation (NATURE, vol xliv p 145), we pointed out that such a book was badly wanted in English We are glad, therefore, to welcome a translation of Dr Ziehen's work, which will serve well as an introduction to the new science of physiological psychology

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The *Volucellæ* as Examples of Aggressive Mimicry

AN interesting point in the *Volucellæ* as examples of aggressive mimicry is the fact that they were first used to support the teleological theories of an earlier day, and were subsequently claimed by natural selection. Thus Messrs Kirby and Spence speak of them (Second Edition, 1817, vol ii, p 223) as affording "a beautiful instance of the wisdom of Providence in adapting means to their end," and after describing the resemblance of the flies to the bees, they continue, "Thus has the Author of nature provided that they may enter these nests and deposit their eggs undiscovered Did these intruders venture themselves amongst the humble bees in a less kindred form, their lives would probably pay the forfeit of their presumption" In this theory of Providence it is hard to see where the bees come in In 1867, A. R. Wallace published an article on "Mimicry and other Protective Resemblances among Animals," which was in 1875 republished in his "Essays on Natural Selection" In this essay (p 75 of the volume) he spoke of this interpretation as the only case in which an example of mimicry had been "thought to be useful, and to have been designed as a means to a definite and intelligible purpose" He accepts it as a product of natural selection, and since that time it has been constantly used as a well-known example of this principle, so well known, indeed, that the history of it became unnecessary in any publication where space was an object.

I neither originated the principle of aggressive mimicry nor the *Volucella* as examples of it, although I accepted, and still accept, both. Under these circumstances I must, in justice to Kirby and Spence and A R. Wallace, repudiate the discovery of a significance I should have been proud to have made, but which was made, as a matter of fact, about half a century before I was born. It is only fair to these writers to say this, for Mr. Bateson, although mentioning Kirby and Spence, seems

throughout to give me the sole, or, at any rate, the chief, responsibility for both hypothesis and examples

In writing my book I made great use of a very interesting series of specimens in the Museum of the Royal College of Surgeons, lately brought together by Prof Stewart The aggressive mimicry of the *Volucellæ* was illustrated in one of these cases, and I briefly described the contents of the case in the passage Mr Bateson quotes I was glad to give a few more details than those supplied by Mr Wallace, and at the same time to mention examples which could be actually seen by readers, for I referred to the collection more than once I was, however, anxious to obtain confirmation from one who had studied the Hymenoptera and their parasites much more minutely than I had, so I referred the proofs to Mr R C L Perkins, a most observant naturalist, specially interested in these insects He made some valuable suggestions, but did not modify the account of the case in the Royal College of Surgeons I think I may claim, therefore, that I took all reasonable precautions to avoid error in a part of the subject which had not then come under my own personal observation Prof Lloyd Morgan, in his interesting "Animal Life and Intelligence," has also mentioned this example, and figures the *Volucella* and *Bombus muscorum* He tells me that his figures were copied from a case in the Natural History Museum, so that my selection appears to be supported by the two great biological museums of London

Within a few weeks of the appearance of my book, I had found out the omission of the other banded humble bees also mimicked by the *mystacea* variety of *Volucella bombylans*, and I showed one of these (I think *B hortorum*) at a lecture given to the British Association at Leeds in 1890 I had intended, and intend, to repair the omission in any reprint that may be required

There is, however, nothing inaccurate in the statement that *B muscorum* is mimicked We require something more than dogmatic assertions and question begging metaphor of tabby-cat and fox to establish this as an error of the two museums and the two volumes which have followed them in this respect Mr Bateson appears to have been studying the literature of *Volucellæ* rather carefully, if he now extends his investigations to the perfect insects themselves, and compares the individuals in a series of moderate length, he will find that the *mystacea* variety differs much in the demarcation of its rings or zones, and also that the appearance of each individual varies with the direction from which it is observed. The less sharply-marked appearances resemble *B muscorum*, the likeness being increased by a slight indication of zoning to be seen in the latter

On July 7 of the present year I captured, in a wood near Newbury, a pair of the variety *mystacea* in copula The male, the larger insect, was unusually indistinctly zoned I have submitted the specimens to Mr Verrall who kindly tells me that the large male is certainly the variety *mystacea*, and he evidently thinks there is nothing remarkable about it On the other hand, the female, which was unusually small, is more interesting, being somewhat an intermediate variety As, Mr Verrall informs me, Rondani has made about a score of intermediate species, this little capture of mine may turn out to be of interest, and it is comforting in a controversy of this kind to be able to add one fresh observation which may be of some use, if only in the way of confirmation

Now as to the statement, in which no ambiguity was intended, that the two varieties lay in the nests of the bees they respectively mimic. This was, as Mr Bateson says, a very general impression, the impression of naturalists who knew these insects far better than I did, an impression which had already been expressed in the case at the College of Surgeons If I was mistaken in adopting it, was it not well that I made the mistake, if by its means the general impression should be corrected, having in my book assumed a tangible shape? What man who cares for the advance of science more than for his own advancement would regret to have made a mistake under such circumstances?

But I am not yet satisfied that the impression is not substantially correct. I do not regard the dimorphism of *V. bombylans* as the unique phenomenon it appears to be in the opinion of Mr. Bateson I fail to see any essential biological difference between it and the dimorphism of many Lepidopterous larvæ—a dimorphism which extends into the pupal stage of most species of the genus *Ephyra*—or between it and the distinct types into which certain butterflies of the genus *Kallima* can be divided according to the colouring of the under sides of the wings, or certain moths of the genus *Triphæna* according to that of the upper sides of the upper wings But we know that in those cases which have been tested, while the majority of the offspring resemble the variety to which the parents belonged, a certain proportion follow the other variety, and when the parents belong to different varieties the offspring are more equally divided It is therefore only to be expected, so far as our present knowledge goes, that both varieties should emerge from the same nest. The important thing to be ascertained, from the point of view of the theory of aggressive mimicry, is not the colour of the offspring which emerge, although this is of high interest on other accounts, *but the colour of the parents which enter* It might be supposed that Mr Bateson would have understood this, but it is perhaps too much to expect from a critic who is so aggressively uninterested.

It would be interesting to know the grounds upon which Mr Bateson considers the dimorphism of *V bombylans* to be almost unique At present he contents himself with assertions If we were ever to return to the *régime* of authority and dogmatism in place of reason and experiment, Mr Bateson's scientific position would be indeed assured

Years ago I was satisfied that the evidence for the statement in my book was insufficient, and this, too, I had intended to modify when the opportunity occurred In lecturing I have often alluded to the investigation as an interesting one, and only a fortnight ago suggested it to the members of the Natural History Society at Marlborough College Two years ago I endeavoured to breed *Volucellæ* in the manner described by Mr Bateson, I am sorry to say without success I may therefore claim that the statement quoted by Mr Bateson had produced no paralysis of effort on my part either as regards my own work or that which I have been able to suggest to others.

I may add that the upshot of this inquiry—even if it lead to the conclusion that both varieties lay indiscriminately in the nests of all the species they resemble—would not, in my opinion, remove the *Volucellæ* from their place as examples of aggressive mimicry, but the working of the principle would be more complex I do not, however, propose to render myself liable to further sneers about "ingenuity" by discussing it on the present occasion

Mr Bateson's letter appropriately ends by putting into my mouth a defence I should never have advanced—a defence which was obviously inserted in order to impute discredit—and then proceeding to the easy task of demolishing it Let me therefore say that a mistake is to me a mistake, whether in a volume intended for the public or a paper presented to a scientific society Indeed, I regret the former more than the latter Unfortunately, too, mistakes are more liable to occur in the volume, because the ground is wider, and passes in some directions into less familiar regions But I can honestly say that I have always done my best to avoid mistakes, and that I correct them as the opportunity arises, in fresh papers or in reprints of volumes And I derive much comfort from Mr Phelps' dictum, which I am sure appeals to every one who works, that "people who never make mistakes never make anything" EDWARD B POULTON

Oxford, October 24.

P S—I wish to take this opportunity of correcting certain mistakes in my book ("Colours of Animals," Internat Sci. Ser), as it may be some time before the book can be reprinted, owing to the number of copies struck off

Pages 49, 50—Dr Hurst informs me that my abstract of Weismann's work on seasonal dimorphism is wrong. This will be carefully reconsidered in any reprint

Page 73—I wish to withdraw the account of *Phrynocephalus* Although the structures alluded to are probably alluring, there is not sufficient evidence as to the manner in which they are used

Page 85—Professor Howes calls my attention to the description of the nerve-terminations in pigment cells.

Page 94, *et seq.*—Sir J Ross should be Captain James Ross.

Page 105—I ought to have added that Mr Sharpe's conclusions are not accepted by Professor Newton

Pages 142-146—Mr. Bateson has shown that the white cocoons of *Saturnia* and *Eriogaster* are not due to the white backgrounds employed, but to disturbance of the larvæ. It is still probable that the principle holds in *Halias prasinana*

Page 156.—For the above reason I withdraw the argument about the cocoons of *Rumia*, although I believe that it still holds if *H. prasinana* be substituted.

Chapters x., xi. should be read in connection with the experiments on Warning Colours since made by Mr. Beddard and published in his volume, "Animal Coloration."

Page 161.—The cockroach is not a good example. As Prof. Weldon pointed out to me, there is no evidence that its unpleasant smell renders it unfit for food. The hive bee would be a better instance.

Page 193, line 7 from bottom.—*Fibrous* should be *fulvous*.

Page 203, line 6 from bottom.—For *suited for* read *bearing*.

Page 208, line 13 from top.—*Divert* should be *direct*.

Page 224.—I have since heard from Mr. Skertchly that he did not intend the argument which I quote at the bottom of the page to be taken seriously.

Page 236.—*Diadema bolina* should be *D. misippus*, and it and the *Danais* it mimics occur in *three* varieties, not in *two*. I owe this to Col. Swinhoe; the error was copied from Trimen. E. B. P.

The Geology of the Asiatic Loess

In the spring and early summer of this year I had the opportunity, in company with Mr. S. B. J. Skertchly, of examining closely the loess deposits of Shantung, stretching from Chefoo to Tsinan, the provincial capital.

The investigation convinced us both that the original loess of China must be regarded as a marine deposit. Subsequent to the time of Mr. Skertchly's leaving the province, on June 17, I was able to supplement these conclusions by the discovery of a band of limestone rocks bored by pholades and crustaceans up to a height of about 1100 feet, above which line no indications of late marine action were visible. The rocks in the locality near Tsinan fu are carboniferous limestones interbedded with dioritic porphyries, and are still horizontal and unbroken for some thousands of square miles, having received their present contour in pre loess ages. The dip for hundreds of square miles in this locality seldom exceeds from 2° to 8°. These facts we hope to make the subject of a joint memoir.

The loess of China has, however, been traced almost continuously beyond the limits of the eighteen provinces to the foot of the Pamîrs. West of the Pamîrs loess occurs in the valley of the upper Oxus, probably in the Kizil Kum, and up to the Caspian, and its marine origin requires us to believe in the submergence within late geologic time of the greater part of Central Asia. Most geologists recoil at such a suggestion, and I am in a small minority in accepting the view that the present distribution of ocean and continent is of very recent date. I may, however, in condonation of heterodox views, refer to the position of the argument with regard to the alleged shifting of the terrestrial axis of rotation, which has within the last few years entered on a new phase. When some years ago I presented these views to the Council of the Geological Society of London they were scouted as utterly untenable. Since that time, while English astronomers have held the view that practically the axis of rotation has undergone, within the limits of observation, no change, American astronomers have come to the conclusion that a secular movement is actually in progress. My own geological observations in Europe, North America, and Asia have led me to infer that the North Pole has within recent geological time shifted, and that a shift is in all probability in progress at the present time along a line following approximately the direction of the 70th meridian of west longitude. This shift is not to be taken to involve a change in the direction in celestial space, but is rather a rolling of the earth over its axis, the latter remaining practically stationary.

Dynamical causes sufficient to account for the change of position of the terrestrial poles, and in consequence of the parallels of latitude, seem to me to be at work. Prof. G. Darwin has calculated the probable change in the position of the pole due to an elevation of the bed of the Pacific Ocean, but no one has touched the converse effect of the change of the pole on the relative levels of the oceans and continents. In addition to the cause suggested in the possible elevation of large tracts of continental land, there are other influences at work tending in the same direction. The different distribution of the large masses of ice around the poles, which probably varies within somewhat large limits, and the slow disturbance of equilibrium resulting from the growth of deltas and deep sea deposits, have frequently been adduced. More important still is perhaps the differential influence of tidal friction in retarding the rotation, the effect of which must be sensibly unequal in the two hemispheres north and south of the equator; another cause may be looked for in the action of aerial currents, the effect of which in the northern hemisphere as containing greater masses of elevated land must be greater.

Another potential cause of shifting has never, that I am aware of, been formulated. Although at present of comparatively small influence, it must at various geological periods have been of great importance. It leads on to dynamic considerations of tidal energy beyond the compass of a letter to explain. The relative part played by the sun and moon, as deduced from gravitational formulæ, does not quite agree with the observed phenomena of our daily tides. It is believed by many that the ordinary lunar tide, affecting mainly the oceanic envelope, is complicated by the presence of a terrene tide largely influenced by the sun, and that the earth does to an appreciable extent yield twice in the twenty-four hours to the deforming force of solar gravitation. So long as this oscillation takes place at regularly recurrent intervals no energy is wasted. Should, however, a sudden snap occur, breaking the rhythm of the oscillation, some energy is evidently spent, and this can only be made up from the *vis viva* of rotation. Such snaps do occur occasionally; the regular oscillation is momentarily suspended, and the waters of the ocean rush in to restore the equilibrium. This is the well-known "tidal" wave that so frequently occurs in connection with earthquakes.

Such a snap on the equatorial line would simply retard the rotational period generally. North or south of this line, as the moments of rotation would be instantly unequal, the sphere would roll over its axis of rotation, and a shift in the position of the poles occur. The earth is not a perfectly rigid mass. Were it as rigid as steel, the interior within a depth of 200 miles would yet, under the pressure of gravitation, behave as a liquid; a shift in the pole would then be met either by a corresponding shift in the equatorial protuberance, or a change in the ocean level; or, more probably, by a compound action of both. In the latter case, to fulfil the conditions of equilibrium, the ocean surface in the neighbourhood of the new equator would rise, and if the shift were sufficiently great, would overflow the lowlands. If the equator, in the longitude of Central Asia, had at any former time passed north of its present position, and the rock masses of the Continent had not been elevated, a mid-Asian sea must have resulted. The undisturbed position of the carboniferous rocks, and the plain evidence that the surface sculpturing of the rocks was of pre-loess age, show that the process was unaccompanied by violent movements.

The theory of the shift of the earth over its momentary axis accounts better than any other for the geological condition of polar lands, and I venture to state it again in brief, as on this occasion the initiative has come from the astronomers, not the geologists. THOS. W. KINGSMILL.

Shanghai, China, August 20.

Note on Mr. Kingsmill's paper

I think it will be difficult for Mr. Kingsmill to adduce evidence of geological changes large enough to produce any considerable shifting of the position of the principal axes of the earth, and accordingly I should feel sceptical as to a theory which postulates that such change has been sufficient to explain considerable changes of climate.

With respect to a later part of the paper, I am entirely at variance with his views. As far as I know "the relative part played by the sun and moon" in producing oceanic tides is in exact accordance with gravitational formulæ.

The existence of a terrene tide is a matter of speculation, but, as the earth cannot be perfectly rigid, it must exist to some extent. The amplitude of the lunar terrene tide must certainly bear to that of the solar the same ratio that holds in the case of oceanic tides, and there is no reason, that I know of, for attributing a greater efficiency to solar action in the case of the deformation of the solid portion of the earth.

I am quite unable to follow the argument by which the so-called "tidal" wave produced by earthquake shock is supposed to produce a retardation of the earth's rotation.

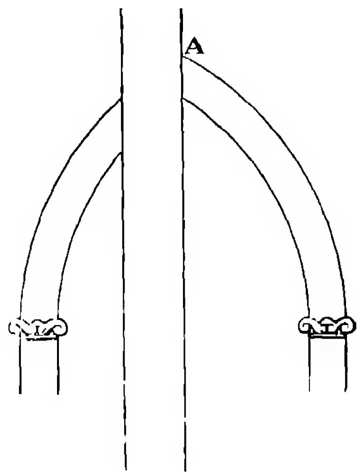
Optical Illusions.

REFERRING to the article in NATURE for October 20, may I mention a rather common optical illusion which I do not remember to have yet seen in print If a gothic arch is unequally divided by a space between two vertical parallel lines, these lines will not only seem to diverge slightly where they intersect the lines of the arch, but the arch itself is caused to appear as if one half had slipped bodily down from the other to an extent



equal to its own thickness In the figure given above it is impossible to believe that but for the intervention of the vertical interlinear space the two halves would be seen to meet perfectly with the apex at A This illusion is worth the notice of architects who desire to avoid the disquieting effect upon the eyes of observant persons which is produced by the intersection of the chancel arch of a church by an intervening pillar

28 Mount Park Crescent, Ealing, W R T LEWIS

A Remarkable Rainfall.

THE rainfall here of October has been so remarkable that it seems worth while to place it on record in your columns Rain fell on twenty-five days during the month, making a total fall of 10 32 inches As the annual rainfall on an average of eleven years is 31 10 inches, it will be seen that very nearly one-third of this amount fell in one month This is by far the highest amount I have recorded since I began to make records in January, 1878, the next highest month being August, 1879 On that occasion five inches fell in thirty hours on the 17th and 18th, and many bridges were carried away in Flintshire and Denbighshire, but the total fall for the month was only 7 89 inches Dr. Nicol, of Llandudno (six miles from here), who has registered the rainfall since, and including 1861, informs me that it amounted last month to 8 56 inches there, this also being the highest month he has ever recorded

In September rain fell on twenty-three days, and though the total fall was only 3 77 inches, yet the constant rain, combined with an unusually low temperature (the mean maximum being only 56°6, and the highest shade temperature 67°4, against 64°6 and 81°2 respectively in 1891), made it almost impossible to get in the harvest ALFRED O WALKER.

Nant-y-Glyn, Colwyn Bay, November 5.

On a Supposed New Species of Earthworm and on the Nomenclature of Earthworms

IN yesterday's NATURE I find that the Rev Hilderic Friend has again given the name *L. rubescens* (Friend) to a supposed new species of earthworm. This worm appears to me to be identical with *Enterion festivum* (Savigny), described under the name *Lumbricus festivus* by Rosa. Though comparatively rare, it is by no means new, nor even new to Britain, though I know of no published record of its occurrence here. I met with two or three specimens among the worms supplied to me when I was working at the chapter on Lumbricus in "Marshall and Hurst," and identified them subsequently by the help of Rosa's table. At the time I took them for mere varieties, and put them into a bottle for future study I believe the specimens are now in the possession of Dr Benham, who has entirely overlooked the species in his "Attempt to Classify Earthworms" (*Quart Journ Micr. Sci* xxxi)

The specific name *terrestris* must also, it appears to me, be dropped Linnæus did not define a species under that name, but applied it to what are now universally regarded as several distinct species The species so called by Mr Friend was, I believe, first defined by Savigny under the name *Enterion herculeum* The diagnostic characters of the species are given by Rosa in his useful table of the species ("I Lumbricidi del Piemonte," p 25), and he calls it *Lumbricus herculeus*, to which name the usual rules of nomenclature bind us

I would therefore suggest the following alterations in Mr Friend's "Chart of the Genus Lumbricus" —

1 For "Terrestris (Linn.)" read "herculeus (Sav)"
2 For "Rubescens (Friend)" read "festivus (Sav)"

Owens College, October 28 C HERBERT HURST

Ice Crystals

DURING the cutting of the formation for a railway I observed on Tuesday morning, the 18th inst, a peculiar series of ice crystals The ground is composed of arenaceous clay largely mixed with sand and small gravel, and is of a very open nature, the surface being covered with moorland grass, rushes, and coarse ferns These crystals were only found in a length of about nine feet, the ground on both sides of the patch being hard frozen

These crystals were acicular, and sprang from a base of very porous opaque ice, but every needle was entirely free and distinct throughout its height, and at first sight appeared to be bound together with two bands, one at one third and the other at two thirds of the height A closer examination proved that the band appearance was due to a slight enlargement of the crystals at these points, the ice being opaque, whilst the needles were perfectly translucent

The average height of these crystals was about one inch, the needles having a diameter of about $\frac{1}{80}$th part of an inch, and were grouped together in clusters of forty or fifty, forming an irregular square of about $\frac{1}{4}$-inch on the side Some of these crystals were growing vertically from the ground, others springing out horizontally from the side of the cutting, and were either straight, curved, or bent round forming a half circle This morning the same form of crystals existed, but were much larger, being fully two inches long On both occasions the air was calm and clear, the min ther reading 30° on the 18th, and 24° to day

Lesmahagow, October 25 C. M IRVINE

Lunar Craters

THE letter and illustration offering a suggestion as to the formation of lunar craters remind me of an experiment I once saw during a chemical lecture, bringing out the same point very clearly

A shallow dish containing a layer of damp sand, $\frac{1}{2}$", was flooded with 1-inch coating of Paris plaister, of the consistence of cream, and the dish set to dry over a Bunsen flame

As the plaister set, the surface was pitted with crater-like holes, formed by the escape of steam from the sand at the bottom of the dish, giving a perfect representation of a lunar surface.

As some of your readers might care to try this experiment, I take the liberty of sending you this "recollection."

M H MAW.

Walk House, Barrow-on-Humber, Hull, Nov 7

A Fork-tailed Petrel.

THE occurrence of a Fork-tailed Petrel as far inland as Macclesfield may perhaps interest some of the readers of NATURE.

It was picked up by a man on the 11th ult., two days after the stranding of the *Sirene* in a gale at Blackpool, and being unacquainted with the species he sent it to me as a curiosity. I identified it as a Fork-tailed Petrel, and Mr J. H Salter, of Aberystwyth College, has kindly confirmed this decision

Some of the feathers on the forehead are tipped with white Does this indicate a young bird, as I can find no mention of it in any of the plumage descriptions that I have seen?

NEWMAN NEAVE.

Rainow, near Macclesfield, November 5.

THE ORIGIN OF THE YEAR[1]

III

IN the previous articles I have endeavoured to show that the Egyptians had the Sirius year and the vague year so related to each other that the successive coincidences of the 1st Thoth in both years took place after intervals of 1460 Sirian years With a real year, the length of which would be brought home to them by the regular recurrence of the solstices and Nile flood (to say nothing of the equinoxes) and the year of 360 days which they would soon find to be quite artificial and unreal, they would be much more likely to refer the dates in the artificial year to the real one, than to take the opposite course, and, as I have shown, the artificial dates would sweep backwards through the real ones Such a method of reckoning, however, would be useless for calendar purposes, as they not only wanted to define the days of the year but the years themselves, and I pointed out that something more was necessary, and that an easy way of defining *years* would be to conceive a great year, or *annus magnus*, consisting of 1460 years, each "day" of which would represent four years in actual time, and further to consider every event, the year of which had to be chronicled in relation to others to take place on the day of the heliacal rising of Sirius or the nearly coincident Nile flood, which, was employed to mark the first year of each series of four

Now as a matter of fact it is known (I have the high authority of Dr Krall for the statement) that each king was supposed to begin his reign on the 1st Thoth (or 1st Pachons) of the particular year in which that event took place, and the fact that this was so supports the suggestion we are considering During the reign its length and the smaller events might be recorded in vague years and days so long as the date of its commencement had been referred to a cycle

We have next to consider more especially the vague year

One argument which has been used to show that a vague year was not in use during the time of the Ramessids has been derived from some inscriptions at Silsilis which refer to the dates on which sacred offerings were presented there to the Nile god As the dates 15th of Thoth and 15th of Epiphi are the same in all three inscriptions, although they cover the period from Ramses II to Ramses III—120 years—it has been argued by Brugsch that a fixed year is in question

Brugsch points out that the two dates are separated by 65 days that this is the exact interval between the Coptic festivals of the commencement of the flow and the marriage of the Nile the time of highest water, and

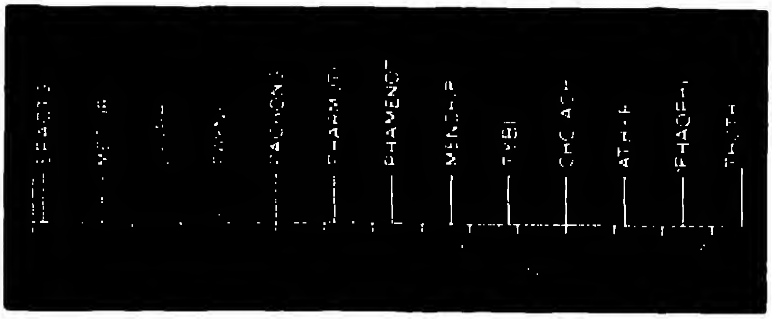


FIG 5.—The distribution of the 1st of Thoth (representing the rising of Sirius) among the Egyptian months in the 1460 year Sothic cycle

as we shall see, occurred, at different periods of Egyptian history, on the 1st Thoth and 1st Pachons

A diagram, which may here be repeated, was given to show how such a system would work From any coincidence of 1st Thoth (or 1st Pachons) in both the Sirian and the vague year, since the vague year is the shorter, the 1st Thoth (to deal only with Thoth) of the vague year would recede, so that in such a cycle it would fall first among the Epacts, then in Mesori, and so on through the months, till the next coincidence was reached.

The diagram will show how readily the cycle year can be determined for any vague year If for instance the 1st Thoth in the vague year falls on 1 Tybi of the cycle, we see that 980 years must have elapsed since the beginning of the cycle, and so on.

Here, then, we have a true calendar system, if the Egyptians had not this, what had they?

Such a calendar system as this it will be seen, however, is good only for groups of four years. Thus during the first four years of a cycle the 1st Thoth vague would happen on 1st Thoth of the cycle, during the next four years on the 5th Epact, and so on

Now a system which went no further than this would be a very coarse one. We find, however, that special precautions were taken to define which year of the four was in question Brugsch[2] shows that a special sign that, therefore, in all probability these are the two natural phenomena to commemorate which the offerings on the dates in question were made

But Brugsch does not give the whole of the inscription A part of it, translated by De Rougé,[1] runs thus —

"I (the king) know what is said in the depot of the writings which are in the House of the Books The Nile emerges from its fountains to give the fullness of life-necessaries to the gods," &c

De Rougé justly remarks, "Le langage singulier que tient le Pharaon dédicateur pourrait même faire soupçonner *qu'il ne s'agit pas de la venue effective de l'eau sainte du Nil à l'une des deux dates précitées*"

Krall (*loc cit* p 51) adds the following interesting remarks —"Consider, now, what these 'Scriptures of the House of Life' were like. In a catalogue of books from the temple of Edfu, we find, besides a series of purely religious writings, 'The knowledge of the periodical recurrence of the double stars (sun and moon),' and the 'Law of the periodical recurrence of the stars'

" . The knowledge embodied in these writings dated from the oldest times of the Egyptian empire, in which the priests placed, rightly or wrongly, the origin of all their sacred rolls" (cf. Manetho's 'History," p. 130)

Now to investigate this question we have to approach some considerations which at first sight may seem to be

[1] Continued from vol. xlvi p. 107

[2] "Matériaux pour servir à la reconstruction du calendrier," p 89

[1] "Aeg Zeit," 1886, p 5, quoted by Krall.

foreign to our subject I shall be able to show, however, that this is not so

Imprimis we must remember that it is a question of Silsilis, where we know both from tradition and geological evidence, in ancient times the first cataract was encountered The phrase "The Nile emerges from its fountains" would be much more applicable to Silsilis, the seat of a cataract than as it is at present We do not know when the river made its way through this impediment, but we do know that after it took place and the Nile stream was cleared as far as the cataract that still remains at Elephantine, a Nilometer was erected there and that during the whole of later Egyptian history at all events the time of the rise of the river has been carefully recorded both there and at Rhoda

From this it is fair to infer that in those more ancient times the same thing took place at Silsilis, if this were so the reason of the record of the coming of the inundation at Silsilis is not far to seek, and hence the suggestion lies on the surface that the records in question may state the date of the arrival *in relation to Memphis time*

So far in my inquiries I have not been able to find a complete discussion of the influence upon local calendars, in different parts of the Nile valley, of the variations of the phenomena upon which the Egyptians depended for the marking of New Year's day

If the *solstice* had been taken alone, the date of it would have been the same for all parts of the valley, but certainly the solstice was not taken alone, and for the obvious reason that they wanted something to warn them of the Nile rise, and in the lower reaches of the river the rise precedes the solstice

Nor was the heliacal rising of Sirius taken alone

As we have seen, according to Biot the heliacal rising of Sirius *at the solstice* took place on July 20 (Julian) in the year 3285 B C, and according to Oppolzer, it took place on July 18 (Julian) in the year 3000 ± B C

But this is too general a statement, and it must be modified here There was a difference of 7 days in the date of the heliacal rising, according to the latitude, from southern Elephantine and Philæ, where the heliacal rising at the solstice was noted first, to northern Bubastis There was a difference of four days between Memphis and Thebes, so that the connection between the heliacal rising and the solstice depended simply upon the latitude of the place The further south, the earlier the coincidence occurred

Here we have an *astronomical* reason for the variation in the date of New Year's day

But it was chiefly a question of the arrival of the Nile flood, and the date of the commencement of the Nile flood was by no means common to all parts of Egypt!

I cannot find any statement of the dates of the arrival of any one Nile flood at places between Elephantine and Cairo Dr Wallis Budge[1] states "The indications of the rise of the river may be seen at the cataracts as early as the end of May"

Now if we take the 1st cataract to be here meant, and deal with May 31, since the average day of arrival of the inundation at Cairo is 3 days after the solstice—that is June 20 (Greg)—we have 24 days for the flood-travel for the 600 miles between Elephantine and Cairo, four-fifths of a month elapsing between the times at which the Green Nile colours the pool at Syene below the Cataracts, and the river at Memphis; so that the further south, the earlier the flood was noted This gives us about a mile an hour. This certainly seems too slow

But if we assume 16 days, this would give us about 15 days between Silsilis and Cairo, and 12 days between Thebes and Cairo, taking Cairo to represent the ancient Memphis. Now this represented a difference in the new year's days of different places, compared to which our modern differences of local time sink into insignificance, for they only touch hours of the day, and the reason that I have referred to them here is to point out that if the assumption made is anything like accurate, if, for instance, in Pepi's time a Nile rise were observed at Silsilis, there might easily be a difference of 15 days between the rise of the Nile at Silsilis and the Memphic 1st of Thoth If both at Silsilis and Memphis the Nile rise marked 1st Thoth, the day of the rise at Memphis would correspond to 15th Thoth at Silsilis, so that a king reaching Silsilis with Memphis local time, would be struck with this difference, and anxious to record it, may not this then have been the important datum recorded in the sacred books? If so, it would not touch the question of the fixed or vague year at all

[1] "The Nile," p. 46

Let it, then, be for the present conceded that there was a vague year, and that at least some of the inscriptions which suggest the use of only a fixed year in these early times may be explained in another way I do not say the above explanation is the correct one, for the assumption of 16 days may be wrong, even if difference in the dates of the heliacal rising at the two places be taken into account

The dates we have found—trying to take the very simplest way of writing a calendar in pre-temple times, and using the calendar inscriptions in the most natural way—are for the coincidence of the heliacal rising of Sirius at, or near, the solstice—

270 B C
1728 B C
3192 B C

Now here we meet with a difficulty which, if it cannot be explained, evidently proves that the Egyptians did not

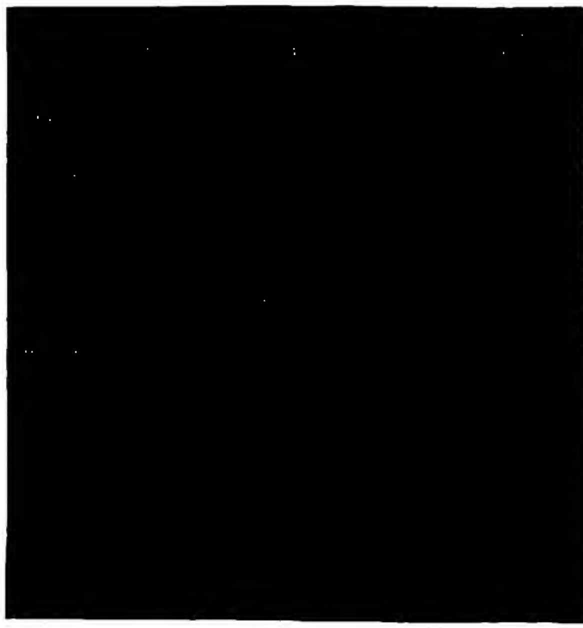

Fig 6.—Julian dates of the 1st of Thoth (vague) from 23 A D to 240 A D

construct and use their calendar in the way we have supposed.

We have it on the authority of Censorinus that a Sothic period was completed in 139 A D, and that there was then a vague year in partial use It is here that the work of Oppolzer is of such high value to us. He discussed all the statements made by Censorinus, and comes to the conclusion that his account is to be depended upon It

has followed from the inquiries of chronologists that in this year the 1st of Thoth took place on July 20 (Julian), the date originally of the heliacal rising of Sirius, the beginning of the year

This being so, then, in the year 23 A D —in which the Alexandrine reform of the calendar, of which more presently, was introduced—the 1st of Thoth would take place on August 29, a very important date Censorinus also said that in his own time (A D 238) the 1st of Thoth of the vague year fell on June 25 Fig 5 will show the connection of these three dates in reference to the vague year The relations of the statements made as to the years 139 and 238 are very clearly discussed by Dr Oppolzer

Oppolzer, then, being satisfied as to the justice of taking the year 139 A D as a time of coincidence of the fixed and vague years—the latter being determined alone by the heliacal rising of Sirius, and, be it remembered, not by the solstices—calculated with great fulness, using Leverrier's modern values, the years in which, in the various Egyptian latitudes, chiefly taking Memphis (lat 30°) and Thebes (lat. 25°), the coincidence between the two Thoths occurred in the previous periods of Egyptian history He finds these dates for latitude 30° as follow —

	Julian year	Historical year [1]
0	− 4235	4236
1	− 2774	2775
2	− 1316	1317
3	+ 139	139
4	+ 1591	1591
5	+ 3039	3039

Now the date which Oppolzer gives for the coincidence which is nearest the date we had previously determined at 270 B C is 139 A.D There is a difference of 409 years

The question is, Can this fundamental difference be explained? I think it can

In the first place, it is beyond doubt that, in the interval between the Ramessids and the Ptolemies, the calendar, even supposing the vague year to have been used and to have been retained, had been fundamentally altered, and the meanings of the hieroglyphics of the tetramenes had been changed—in other words, the designations of the three seasons had been changed.

On this point I quote Krall in a note.[2]

[1] It should be observed that a distinction is made between the Julian and the historical year This comes from the fact that when astronomical phenomena are calculated for dates B C, it must be remembered that chronologists are in the habit of designating by 1, or rather by − 1, the first year which precedes the instant of time at which the chronological year commenced, while astronomers mark this year in their tables by 0 It follows, therefore, that the rank of any year B C is always marked by an additional unit in the chronological dates. For the Christian era, of course, chronologists and astronomers work in the same way The following table, given by Biot, exhibits the connection between these two methods In the latter Biot shows the leap-years marked B, and the corresponding years in the Scaligerian chronological period are also given

Dates of Julian Years commencing on January 1

According to Chronologists.	According to Astronomers	Corresponding years of the period of Scaliger
− 6	− 5	4708
− 5B	− 4B	4709
− 4	− 3	4710
− 3	− 2	4711
− 2	− 1	4712
− 1B	− 0B	4713B
Physical instant when the era commenced		
+ 1	+ 1	4714
+ 2	+ 2	4715
+ 3	+ 3	4716
+ 4B	+ 4B	4717B
+ 5	+ 5	4718

[2] *Loc cit* p. 29. "It is well known that the interpretation of the seasons and the months given by Champollion was opposed by Brugsch, who propounded another, which is now universally adopted by experts. Something has happened here which is often repeated in the course of Egyptian history —the signs have changed their meaning Under the circumstance that the vague year during 1461 years wanders through the seasons in a great cycle, it is natural that the signs for the tetramenes should have changed their significations in the course of millenniums

"While Thoth was the first month of the inundation in the documents of the Thutmosids and Ramessids, we have in the time of the Ptolemies the month Pachons as the first month of the flood season Whilst Brugsch's explanation is valid for the time of the Ramessids, it is not so for that of the Ptolemies, to which Champollion's view is applicable"

The three hieroglyphic signs used for the tetramenes are supposed to represent water, flowers, and a barn, and the natural order would be that the first should represent the inundation, the second the sowing which succeeds it, and the last harvest time If this be conceded, the initial system would have had the month Thoth connected with the water sign, as Thoth in early Egyptian times was the first inundation month But in the times of the Ramessids even this is not so Thoth has the sowing sign assigned to it In the time of the Ptolemies the flood is no longer in Thoth, but in Pachons, and Pachons has the barn sign attached to it, while the month Thoth is marked by the water sign, thereby bringing back the hypothetical relation *between the name of the month and the sign*, although, as we have seen, Thoth is no longer the flood month

Egyptologists declare that all or at least part of this change took place between the periods named, they are undoubtedly justified as regards a part

At one point in this interval we are fortunately supplied with some precise information In the year 238 B C. a famous decree was published, variously called the decree of Canopus and the decree of Tanis, since it was inscribed on a stone found there

It is perfectly clear that one of the functions of this decree was to change, or to approve an already made change in, the designation of the season or tetramene in which the inundation commenced, from Thoth to Pachons

Another function was to establish a fixed year, as we shall see presently We must assume then that a vague year was in vogue prior to the decree Now the decree tells us that at its date the heliacal rising of Sirius took place on 1 Payni Assuming that this date had any relation to the system we have been considering, the cycle to which it belonged must have begun

Days	
5	Epacts
30	Mesori
30	Epiphi
30	Payni
95 × 4 = 380 years previously, that is, in the year 618 B C.	

Now here at first sight it would seem that the Sothic cycles we have been considering have no relation to the one now in question; for, according to my view, the last Sothic cycle began in 1728 B.C

A little consideration, however, will lead to the contrary view, and show that the time about 600 B C, was very convenient for a revision of the calendar

In the first place nearly a month now elapsed between the coming of the flood and the heliacal rising, and in the second, by making the year for the future *to begin with the flood*, a change might be made involving tetramenes only.

Thus, commencement of cycle		1728 B.C
Epacts	5	
Two tetramenes	240	
Month between flood and rising of Sirius	30 [1]	
	275 × 4 =	1100
		628 B C.

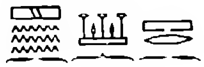
Nor is this all A very simple diagrammatic statement will show what might also have happened about 618 B.C

[1] Probably too great a value by 2 or 3 days.

if a reformer of the calendar (and one especially of conservative tendencies) appeared upon the scene, who believed that the ancient sign for the inundation-tetramene was the water sign, and that the ancient name was Thoth Finding the cycle beginning in 1728 with the signs as shown—

1728 B C Thoth Phaophi Athyr Choiach Tybi Mechir Phamenot Pharmuti Pachons Payni Epiphi Mesori

when starting fresh, he would seize the opportunity of effecting a change, not only by dealing with a tetramene, but he would change the names of the tetramenes allocated to the signs



B C 618 Thoth Phaophi Athyr Choiach Tybi Mechir Phamenot Pharmuti Pachons Payni Epiphi Mesori

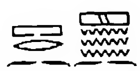
As Krall remarks, it was almost merely a question of a change of the sign! It really was more, because the new tetramene began with the flood

Assuming this, we can see exactly what was done in 238 B C, i e about 380 years later We have seen that the 380 years is made up of

5 Epacts
30 Mesori
30 Epiphi
30 Payni

$95 \times 4 = 380$

the heliacal rising of Sirius occurring on 1 Payni, having swept backwards along the months in the manner already explained We had then—



B C 238 Pachons Payni Epiphi Mesori Thoth Phaophi Athyr Choiach &c

To sum up, so far as we have gone we have the three inscriptions at Philæ, Elephantine, and the still more ancient one of Pepi, indicating on the simple system we have suggested beginnings of Sothic cycles on the 1st Thoth about the years

270 }
1728 } B C
3192 }

On the other hand, we have the decree of Canopus, giving us by exactly the same system a local revision of the Calendar about 600 B C. I say *about* 600 B C because it must be remembered that a difference of $2\frac{1}{2}$ days in the phenomena observed will make a difference of 10 years in the date, and we do not know in what part of the valley the revision took place, and therefore at what precise time in relation to the heliacal rising the Nile-rise was observed

Whenever presumably it took place, New Year's day was reckoned by the Flood, and the rising of Sirius followed nearly, if not quite, a month afterwards. The equivalent of the old 1st Thoth was therefore 1 Payni In months, then, the old 1st Thoth was separated from the new one (= 1 Payni) by 3 months (Payni, Mesori, Epiphi) and the Epacts.

In this way, then, we can exactly account for the difference of 409 years referred to above as the dates assigned by Censorinus and myself for the beginning of the Sirius cycle

Difference between 270 and 239	=	31	years
3 months = 90 days × 4	=	360	,,
5 epacts × 4	=	20	,,
		411	,,

The difference of two years is equal only to half a day!

It seems, then, pretty clear from this that the suggestion I have ventured to make on astronomical grounds may be worth consideration on the part of Egyptologists If our inquiries have really led us to the true beginnings of the Sothic periods, it is clear that those who informed Censorinus that the year 139 A D was the end of a cycle omitted to tell him what we now can learn from the decree of Tanis

J NORMAN LOCKYER

(*To be continued*)

TECHNOLOGICAL EXAMINATIONS

THE report of the results of the Technological Examinations, held this year under the direction of the City and Guilds of London Institute, has a special interest, seeing that after this year the system of payment on results in connection with all classes outside the Metropolis will be discontinued There is no doubt that the offer of payment to teachers helped very greatly in 1879 to stimulate the formation of technical, as distinct from science, classes, and the great extension of this work of the Institute is largely due to the offer then wisely made of contributing towards the cost of instruction The tables furnished in the report, and the diagram of results, are very interesting as showing the great development of these trade classes Since 1880 the number of candidates for examination has increased more than tenfold, the numbers being 816 in 1880 and 8,534 in 1892 In 1885 there were 263 technological classes in different parts of the country, and in the session 1891–2 this number had increased to 610 There is, of course, a corresponding increase in the number of students in attendance at these classes In 1881 the number of students was 2,500, this year it was 16,565 This record of progress is certainly satisfactory, and particularly so, seeing that prior to 1891 there was no sort of organization to carry on the work of directing and assisting technical classes for artisans in different parts of the country As a pioneer movement, the work of the City Guilds Institute has been eminently successful, and many of the Technical Schools which have now been brought under the control of County Councils undoubtedly owe their origin to the technological classes promoted by the City Guilds The question now demanding attention is the future of these classes Much is to be said in favour of associating them more closely with the science classes, which are held in the same schools, but what is wanted for the permanent improvement of such classes is a system of efficient inspection by persons competent to advise County Councils with respect to the important work now under their control

From the report and programme it appears that year by year the Institute adds to the extent and efficiency of its examinations by the introduction of new subjects and of practical tests. Practical examinations were held this year for the first time in photography, goldsmiths' work, boot and shoe manufacture, and in wood-working in connection with the examination in manual training for teachers of public elementary schools This last examination is somewhat different in kind from the other examinations of the Institute. It is not a trade examination. Its purpose seems to be to encourage instruction of a distinctly educational character. Moreover, it is a

close examination None but teachers of public elementary schools are eligible, and these must have regularly attended a course of practical lessons in a registered class under a teacher approved by the Institute Notwithstanding these restrictions, 615 candidates presented themselves at the first examination held by the Institute, and of these 350 passed, 195 obtaining the Teacher's Certificate

The report contains full statistics of the results of the examinations in each of the 61 subjects included in the programme, and it also shows the results in each of the 210 towns where the examinations were held Of the centres outside London, Manchester sent up the largest number of successful candidates, whilst Glasgow, Dundee, and Leeds come next in order The report calls attention to the fact that the proportion of candidates to the population is far less in London than in Manchester, whilst the hope is expressed that the larger facilities for technical instruction which will be available within the next few years will lead to an increase in the number of students and of candidates for examination This increase will no doubt take place with the opening of new polytechnic institutions, but we venture to think that the real improvement in technical education cannot be correctly measured by any mere increase in the number of candidates for examination It depends much more upon the character and quality of the instruction which the candidates receive The great defect of our present organization is the poverty in knowledge and practical experience of the teachers of our science and technical classes Some improvement in the qualifications of teachers, and in the conditions of their training, is needed before progress can be measured by the increase in the number of students in attendance, or of candidates for examination

We notice that in future the Institute proposes to award two kinds of certificates—the one kind to students who have regularly attended a course of instruction under an approved teacher, and the other to candidates who may present themselves for examination without giving any evidence as to their training In this way the Institute proposes to combine the functions of a teaching and an examining body The certificate indicating that the candidate has received some training at a school of recognized position will doubtless acquire a distinct value, but much will depend upon the ability and the reputation of the teacher under whom the candidate may have studied

Of the many alterations in the new programme the most important is the addition of a practical part to the examination in mechanical engineering This examination of the Institute has never seemed to us wholly satisfactory, as overlapping, to too great an extent, the examinations of the Science and Art Department in applied mechanics, machine construction, and steam But in future the examination will consist of two parts, one of which will be distinctly specialized with a view to the candidate's occupation Moreover, in the honours grade, candidates will be required to undergo a practical examination in either machine designing or workshop practice. At the last examination in this subject 966 candidates presented themselves, of whom 536 passed It is satisfactory to note the continuous increase in the number of candidates In plumbers' work, a trade in the successful practice of which every householder is interested In this subject a high standard for passing is wisely maintained Of the 816 candidates who presented themselves, 235 came up for the practical part of the examination, and of these only 85 succeeded in passing in both parts of the examination, and are qualified for certificates.

There is little doubt that the statistics furnished in this report go far to show that a high value is attached by artizans and their employers to the Institute's certificates, and that the progress of technical education has been advanced by the cautious and judicious manner in which the Institute has conducted this department of its operations

ROBERT GRANT.

In Robert Grant, who at the ripe age of seventy-eight died at the place of his birth, Grantown-on-Spey, on October 24, 1892, science loses one of her ablest historians His education was interrupted by a serious illness, which confined him to his bed from his fourteenth to his twentieth year. With surprising energy, however, on his recovery he set about the study of mathematics and the acquisition of ancient and modern languages After studying for a time at King's College, Aberdeen, he went to London to collect materials for a history of physical astronomy Thence he proceeded to Paris in 1845, where for two years he attended the lectures of Arago at the Observatory, and those of Leverrier and others at the Sorbonne Returning to London, he lost little time in beginning the great work with which his name will always be associated It was published in numbers, the first of which appeared in September, 1848, but it was not until March, 1852, that the whole work was issued It bears the title "History of Physical Astronomy from the Earliest Ages to the Middle of the Nineteenth Century, comprehending a detailed account of the establishment of the Theory of Gravitation by Newton, and its development by his successors, with an exposition of the progress of research in all the other subjects of Celestial Physics" Most completely do the contents of the volume fulfil every expectation raised by this comprehensive programme The fame of its author was at once established Four years later he received from the hands of the late Mr Manuel J Johnson, President of the Royal Astronomical Society, the gold medal, then for the first time awarded for literary service to astronomical science One paragraph of the address delivered on that occasion may here be quoted as characterizing most justly the work as well as its author "Throughout the book no one can fail to be struck with the rare skill, integrity, and discernment the author has displayed in tracing the successive stages of progress, or with the scrupulous care he has taken to assign to each of the great men whom he reviews their proper share in the common labour Nowhere is this more conspicuous than in the discussion relative to the discovery of the planet Neptune. By a simple narration of facts he has placed the history of that great event in so clear and so true a light, that I believe I am not wrong in saying he has gained an author's highest praise under such circumstances—the approval of both the eminent persons concerned' Even now, forty years after its publication, the "History" has lost none of its value as a mine of information, and as a delightful guide to those who desire to make a closer acquaintance with the astronomers of the past, as well as their works.

For some time Mr. Grant edited the "Monthly Notices" of the Royal Astronomical Society, and was a member of their Council. In conjunction with the late Admiral Smyth, he translated and edited Arago's "Popular Astronomy" (2 vols 1855 and 1858). Meanwhile his health had so far improved that in 1858 he was able to go through a course of observational astronomy at Greenwich Observatory In the following year, on the death of Prof J Pringle Nichol, he was appointed Professor of Astronomy, and director of the Observatory in the University of Glasgow.

As a member of the party that went to Spain in the troop-ship *Himalaya*, to observe the total solar eclipse of July 18, 1860, Prof. Grant, from his station near Vittoria, had the satisfaction of seeing a portion of the chromosphere, the existence of which as a thin layer en-

veloping the photosphere he had abundantly demonstrated in the winter of 1850-51, from a discussion of all the observations extant ("History," pp 395, 396). It can excite no surprise that Prof Grant assumed the red layer and also the prominences to shine by reflected light, when it is recollected that the sun's light and heat were then supposed to originate wholly in the photosphere while the nucleus was thought to be so cool as possibly to be habitable When Prof Grant took charge of the Glasgow Observatory the only useful instrument he found was the transit-circle by Ertel and Son, of Munich, but through the liberality of a few friends, chiefly in Glasgow, a nine-inch Cooke Equatorial was added to the Observatory some years afterwards After thoroughly testing the transit-circle the new director commenced a series of observations of Mercury, Neptune, the minor planets, and a selection of stars from the British Association Catalogue Gradually, however, his attention was concentrated entirely on the stars the list being correspondingly expanded The observations of planets were communicated from time to time to the *Astronomische Nachrichten* or to the "Monthly Notices"

The stellar observations were published at the expense of her Majesty's Government in 1883 in the well-known "Catalogue of 6415 Stars for the epoch 1870, deduced from Observations made at the Glasgow University Observatory during the years 1860 to 1881, preceded by a Synopsis of the Annual Results of each Star arranged in the order of Right Ascension"

In the introduction will be found a discussion of the Proper Motions of 99 stars A very complete and appreciative review of this work from the pen of Prof Auwers of Berlin appeared in the *Vierteljahrsschrift der Astronomischen Gesellschaft* (19 Jahrgang) The Glasgow star places were at once looked on with confidence by the numerous observers of comets and minor planets One point connected with the Catalogue deserves special mention, viz that, although the observations from which it is derived extend over a space of twenty-one years, the work appeared within two years of the close of the series This promptitude excites the greater admiration when we learn that, exclusive of Prof Grant's personal share in the work, no less than thirteen young assistants at various times took part in the observations, and two others in the computations Many of these personal changes, each of which brought its quota of extra work to Prof Grant, were no doubt in some measure due to the smallness of the allowance provided for assistance, viz £100 per annum Prof. Grant, however, was the last man to waste his energies in useless complaint, and dismisses this point with the remark that "in recent years the work of scrutinizing, reducing to a common epoch, and combining together the vast mass of the observations of the catalogue, extending over a period of more than twenty-one years, has pressed very heavily upon the slender resources of the observatory" The important time service of the City of Glasgow was originated by Prof Grant some thirty years ago, and continues in operation up to the present moment In 1855 he received from the University of Aberdeen the degree of M A, followed by that of the honorary LL.D in 1865, in which latter year he was elected a Fellow of the Royal Society of London For three years he presided over the Philosophical Society of Glasgow, to whose proceedings he made various contributions It may also be noted that among his writings are two remarkable letters proving beyond a shadow of a doubt the spurious character of the pretended Pascal correspondence. These letters were printed in the *Comptes Rendus* by special permission of the French Academy

In manner Prof. Grant was singularly vivacious, and to the last he greeted with the warmest enthusiasm every fresh discovery in the science to which his life was devoted. R. C.

NOTES

THE following is the list of names recommended by the President and Council of the Royal Society for election into the Council for the year 1893 The ballot will take place at the anniversary meeting on November 30 —President, The Lord Kelvin, D C L, LL D, treasurer, Sir John Evans, K C B, D C L, LL D, secretaries, Prof Michael Foster, The Lord Rayleigh, D C.L, foreign secretary, Sir Archibald Geikie, LL.D, other members of the Council, Captain William de Wiveleslie Abney, C B, Sir Benjamin Baker, K.C M G, LL D, Prof Isaac Bayley Balfour, William Thomas Blanford, Prof George Carey Foster, Richard Tetley Glazebrook, Frederick Ducane Godman, John Hopkinson, Prof Joseph Norman Lockyer, F R A S, Prof. John Gray McKendrick, William Davidson Niven, William Henry Perkin, LL D, Rev Prof B Price, The Marquess of Salisbury, K.G., Adam Sedgwick, Prof William Augustus Tilden

AN international subscription for a testimonial to M Pasteur on the occasion of his seventieth birthday on December 27 is to be opened by the French Academy of Science Many men of science in all parts of the world will be glad to have this opportunity of expressing their high appreciation of M Pasteur's labours

SOME time ago we announced that Baron Nordenskiold proposed to edit a number of very remarkable letters and memoirs of Carl Wilhelm Scheele, who died in 1786 It has now been decided that the one hundred and-fiftieth anniversary of the birth of this great Swedish chemist, on December 9, shall be made the occasion of a brilliant celebration in his native country A monument to Scheele is to be unveiled in Stockholm

THE Naturforschende Gesellschaft of Danzig are issuing invitations to the celebration of the 150th anniversary of their foundation on January 2 and 3, 1893 The meetings will take place on the Monday evening in the Friedrich-Wilhelm-Schutzenhaus, and on the Tuesday morning in the large hall of the Landeshaus, and the proceedings will wind up on the latter day with a dinner at 4 p m in the Schutzenhaus.

PROF. EDWARD PRINCE, of Glasgow, has been offered the important post of Commissioner and General Inspector of Fisheries for Canada by the Dominion Government, and has accepted the office Prof Prince is well known as an authority in Fishery Science. He holds the chair of Zoology in St Mungo's College, Glasgow, and is President of the Anderson's College Scientific Society, and Vice-President of the Glasgow Natural History Society

IT is announced that the King of Italy will open in person the International Medical Congress, which is to be held in Rome next year An English committee is being formed to do what it can to secure the success of the Congress

THE New York Academy of Sciences has organized a Biological Section, which is to hold monthly meetings. The opening meeting, at which Prof H. F Osborn presided, was held on October 17.

THE Victoria University has issued a list of University Extension lectures which are to be delivered in the course of the session 1892-93. They are to be given at many different centres, and include a wide range of subjects, among which various departments of physical and natural science hold a prominent place.

LIVERPOOL has sustained a real loss by the death of Mr. T J. Moore, the late curator of the Liverpool Derby Museum Mr Moore had a wide knowledge of various branches of science, and did much to foster popular interest in the results of scientific inquiry. He died on October 31.

DURING the latter part of last week the weather continued very unsettled, the depressions which advanced from the Atlantic causing strong southerly winds or gales in many places, with frequent and heavy rain, while the temperature was uniformly high for the time of year, the daily maxima reaching nearly 60° in the southern parts, and exceeding 50° in the northern parts of the kingdom On Saturday night a considerable decrease of temperature occurred, owing to the advance of an anti cyclone which subsequently spread over most of the country, the southerly winds gradually disappeared, and were succeeded by calm and variable airs In the early part of the present week fog became prevalent in many parts of England, but the weather was generally fair with frosts over the inland districts On Tuesday, however, fresh depressions were passing along our north-west coasts, and rain squalls became general over Ireland and Scotland, while southerly winds again became prevalent. The *Weekly Weather Report*, issued on the 5th instant, showed that the rainfall greatly exceeded the mean in the east and south of England, while in Scotland and the northern parts of England the fall was below the average Since the beginning of the year, the eastern, Midland, and north-west districts of England have had three inches of rainfall in excess of the normal amount, while in the south-west of England there is a deficiency of 7 6 inches

THE U S Hydrographic Office has issued a chart showing the submarine cables of the world, with their principal land connections. The chart is described by *Goldthwaite's Geographical Magazine* as a necessity to foreign commerce It contains tables for the computation of rates to any part of the world

THE November number of the *Kew Bulletin* contains sections on coffee cultivation in British Honduras, the prune industry of California, sugar cane borers in the West Indies, sisal hemp industry in Yucatan, Liberian coffee in the Malay native states, and Bombay aloe fibre There are also miscellaneous notes, from one of which botanists will be glad to learn that after many unsuccessful attempts to introduce living examples of the interesting plant, *Dischidia rafflesiana*, Kew has at last succeeded, thanks mainly to the generosity of Dr Treub, the distinguished director of the Botanic Gardens, Java, who sent a plant of it in a Wardian case two years ago This plant is now established and growing freely, producing numerous large pitcher-like leaves as well as the small normal hoya like foliage The morphological meaning of these pitchers has not yet been thoroughly worked out. "The species of dischidia all want a careful study. They cannot be described satisfactorily from dried specimens The leaves change in form, and it is not ascertained in respect of many species whether they may or may not be converted into pitchers (ascidia)" (Hooker in "Flora of British India") The plant at Kew is now under the special observation of Dr Scott, hon keeper of the Jodrell Laboratory *D bengalensis* is an old garden plant It is cultivated at Kew in the Palm House. *D rafflesiana* is for the present kept in one of the propagating pits.

AT the opening meeting of the twelfth session of the Junior Engineering Society on November 4, an excellent address was delivered by the president, Dr. John Hopkinson, F R S, on the cost of electric supply His general conclusion on the subject is that to be ready to supply a customer with electricity at any moment he wants it, will cost those giving the supply not much less than £11 per annum for every kilowatt, that is for every unit per hour, and afterwards to give the supply will not cost very much more than ½d per unit. The clear apprehension of this point Dr. Hopkinson believes to be essential to the commercial success of electric supply It is hopeless, he thinks, for electricity to compete with gas in this country all along the line, if price is the only consideration. But with selected customers, electricity is cheaper than gas Surely, he adds, it is the interest of those who supply electricity to secure such customers by charging them a rate having some sort of relation to the cost of supplying them.

AN address delivered by Prof. Virchow at the opening of the recent International Congress of Archæology at Moscow is printed in the current number of the *Revue Scientifique* Prof Virchow repeats in this address what he has often said before—that no trace of "the missing link" between man and the lower animals has been discovered either in the human skulls which are believed to be most ancient or in the physical organization of modern savages He urges that the immediate task for anthropologists is to explain the origin of the existing human races, and to determine the causes by which these races, while retaining the power of hereditary transmission, have acquired their distinctive characteristics At first sight, he says, it is easy to suppose that a dolichocephalic skull may be transformed into one of brachycephalic form, but it has not yet been shown that any dolichocephalic race has been actually transformed into a brachycephalic one, or *vice versâ* Prehistoric anthropology ought, he thinks, to find methods which would facilitate the recognition of the types of ancient races and peoples, and enable us to find them again among the races and peoples of the present day It ought also, as occasion offers, to collect data with regard to those strange individual cases about which theories, as Dr Virchow holds, have been prematurely formed, and which should be kept in "the scientific baggage" until we have secured intermediate links which will render it possible for us to unite them in a series

ACCORDING to an official report of Captain von François, the dromedaries which have been introduced into the German territories in South-west Africa in connection with the parcel post service have more than fulfilled the expectations that had been formed about them The climate suits them, and they are not affected by any of the prevalent cattle diseases On the road between Lehuititang and Geinab they were six days without water, and on the seventh day, at Geinab, they did not seem to be very thirsty In stony regions their feet do not, like those of unshod horses or oxen, suffer any injury When loaded with a weight of 250 pounds, a dromedary advances at much the same rate as an ox-waggon. The only drawback connected with these useful creatures is that they are rather costly.

MR A E DOUGLASS, first assistant at the Boydun station of the Harvard College Observatory, Arequipa, contributes an interesting paper to *Science*, October 21, on indications of a rainy period in Southern Peru. There is evidence to show, he thinks, that for many thousands of years, going back far beyond the recognized period of human habitation, the climate of Peru has been very much as it is at present That was preceded by a slow rise of the land out of the sea, which caused the climate to change from wet to dry But under the wet climate the elevation of the land was still too great, and perhaps the duration of the epoch was too short, to produce a luxuriant tropical vegetation, otherwise there would be to-day extensive coal-fields. The wet climate, however, was sufficient greatly to alter the face of the country Lake Titicaca was of enormous area, fed perhaps by the melting glaciers. In the almost continuous rainy season, huge turbid rivers roared and tumbled down these western slopes of the Cordillera, while on each mountain summit vast quantities of snow fell, only to pursue its way down the steep slopes, carving out valleys, building up ridges, and by its melting wearing out deep ravines, which grow smaller as they become lost in the broad level plain below Under such luxuriance of moisture the valley of Arequipa must have teemed with animal and vegetable life, the barren hills to the south were clothed in green, and the desert of La Joya blossomed like a garden.

A CAPITAL annotated catalogue of the mammals collected by Dr W L Abbott in the Kilima-Njaro region, East Africa, has been prepared by Mr F W True, and printed in the Proceedings of the fifteenth volume of the U S. National Museum, with several plates Dr Abbott has presented to the National Museum many African collections, but none of them, according to Mr True, is of more interest than the collection of mammals The specimens have been prepared with much care, the skins being almost invariably accompanied by the skulls and furnished with labels giving the locality and date of capture, sex, and other data In determining the species Mr True has found it necessary to depend almost exclusively on the literature, on account of the lack of specimens for comparison, but the identifications have been made with much care, and may, he thinks, on the whole, be relied upon Several species apparently new are represented in the collection *Dendrohyrax validus*, *Mus aquilus*, *Dendromys nigrifrons*, *Sciurus undulatus*, *Cephalophus spadix* On one who has studied the North American mammalian fauna in detail, Mr True says, the thought impresses itself that the condition of species, as regards variation, is different in the Ethiopian and Nearctic regions In North America individual variation seems far less extensive than in Africa, while geographical variation appears to be more extensive and constant In Dr Abbott's collection great individual variation is especially apparent in the genera *Galago*, *Genetta*, and *Canis* It is true that the species of the last named genus everywhere present much individual variation, but in North America its chief variations appear to be geographical in character The known range of several species is considerably extended by Dr Abbott's labours

AN important contribution to spectroscopy appears in No 10 of Wiedemann's *Annalen* in the shape of a paper on the infra red emission spectrum of the alkali metals, by Benjamin W Snow The method is distinguished by the adoption of a modified form of the bolometer and a very delicate galvanometer with quartz fibre suspension The fibre, supplied by Prof Boys, was 40 cm long With a scale at a distance of 3m, a deflection of 1mm corresponded to a current of $1\ 5 \times 10^{-11}$ amp The spectra were obtained by means of a silicate flint prism, so as to avoid the overlapping of the infra-red spectra which seems to be inevitable where gratings are used Since no infra-red lines could be traced in the spectrum produced in the Bunsen or the oxy-hydrogen flame, the electric arc was used, the current being derived from the very uniform Berlin Central supply The best arrangement for the arc was found to be a hole bored through the centre of the carbon, containing a "wick" of the compressed salt. The bolometer consisted of two platinum-thread resistances. A platinum wire embedded in silver was hammered flat, so as to have a breadth of 0 05mm and a thickness of 0 00036mm Two such threads were fastened side by side with shellac on a mica frame One of them was blackened in a turpentine flame and exposed to the light, the other being covered The difference of resistance produced by the incident rays was measured by a Wheatstone bridge arrangement, with a shunt contrivance for enlarging the scale of the bridge wire The resistance of each of the platinum ribbons under ordinary conditions was 75 ohms. The other branches of the bridge were made of German silver wire. The slit of the spectrometer was adjusted to 0 1mm, corresponding to an angle of 1 68 minutes of arc in the spectrum, whilst the breadth of the platinum thread corresponded to an arc of 1'·6 The current through the bridge was maintained at one-fortieth ampere. In the measurement of the intensity of the lines, the energy of radiation was taken as proportional to the first throw. It was found that a standard candle at 1m. distance gave a throw of 150mm. A preliminary investigation of the carbon spectrum revealed a large number of bands reaching up to λ 20620, the principal less refrangible bands being between

7000 and 7700
7850 and 8600
9000 and 10000
10750 and 11600
13700 and 15000

These were made up of innumerable fine lines It was also observed that the carbon spectrum vanished in comparison with the metallic spectrum as soon as the latter was brought into play Of the five metals investigated, viz, sodium, potassium, rubidium, lithium, and cæsium, the two rarest were found to be specially rich in infra-red lines Sodium showed maxima at 818-, 11270, 12400, and 18360, potassium at 7670, 10820, 11580, 12250, and 14610, lithium at 8070, rubidium at 7910, 9980, 13120, and 14760, and cæsium at 8380, a large one at 8820, and others at 9980, 13270, and 14530 Kayser and Runge's empirical law for the alkalies was confirmed for the infra-red of lithium and sodium, but not for the other three metals.

MR ELLIOTT COUES, of the Smithsonian Institution, defends in *Science* the rule, in biological nomenclature, "once a synonym, always a synonym," for the form of which he believes himself to be in some degree responsible He illustrates the real meaning of the aphorism in the following way. Let there be a genus *Smithia* in botany Let a genus *Jonesia* then be named Let *Jonesia* then be found to be the same genus as *Smithia* Then the name *Jonesia* "lapses into synonomy," and cannot be thereafter applied to any other genus in botany That is all that is meant by the saying "once a synonym always a synonym" In other words, if *Jonesia* is not good for what it originally meant, it is good for nothing, it is to be deleted absolutely, and cannot come into re-existence by transfer to any other genus Mr Coues shows that the same principle holds for all specific names within their respective genera Example Let there be a *Rosa Smithi* Let some one then name a *Rosa Jonesi* Let *R Jonesi* be considered to be the same species as *R Smithi* Then there can never be a *R Jonesi*, that is to say, no other species of *Rosa* can be specified as *Jonesi* But, of course, if any one discovers, after this reduction of *Jonesi* to a synonym of *Smithi*, that what had been called *R Jonesi* is a good species, then *Jonesi* revives as the name of *that* species, and the fact that it had been (erroneously) regarded as a synonym of *Smithi* is no bar to its use in its original sense

THE Geological Survey of America has published a paper, by Mr J S Diller, on the Geology of the Taylorville region in the Sierra Nevada, California, immediately north of the fortieth parallel In this region there are eighteen sedimentary formations and seventeen eruptive masses The former have a total thickness of 24,500 feet, 17,500 feet are probably Palæozoic, and 7000 feet are Mesozoic Among the sedimentary rocks, one horizon in the Silurian, two in the Carboniferous, three or more in the Trias, and five in the Jura have been definitely recognized by fossils Among the eruptives there is great variety Their extravasation, beginning early in the Palæozoic, recurred vigorously in the Triassic and at the close of the Jurassic, and, finally, also in the Neocene and Pleistocene The dioritic rocks of the region are a portion of the great granitoid mass of the upper Sierra Nevada, and are evidently eruptive, with well-defined contact phenomena in Triassic formations. Their eruption is certainly post-Triassic, and may have taken place immediately at its close or after the deposition of the Jurassic. There are at least four unconformities in the geologic column of the Taylorville region. During the greater part, if not the whole, of the Palæozoic, the sea covered the region now occupied by the northern portion of the Sierra Nevada The great disturbance at the close of the Carboniferous may

have been accompanied by an uplift, forming land during the early Triassic, but if so, it subsided and was ready to receive the deposits of the upper Triassic. The disturbance at the close of the Triassic formed no land in the northern Sierra region, but that which closed the Jurassic was accompanied by a great upheaval, excluding the sea to the western base of the Sierras The general structure of the Taylorville region involves a synclinal and two limiting anticlinals After the folds were overturned toward the north-east, the Grizzly anticlinal was affected by an overthrust fault in the same direction The throw along this fault in the older strata is so much greater than in those of Jurassic age as to suggest that a large part of the displacement took place at the close of the Triassic, and was followed by movement on the same plane at the close of the Jurassic.

MR STANFORD has issued an interesting and valuable contoured map of the county of London The scale is three inches to a mile The contour lines or lines of equal altitude are drawn at 25 feet intervals. The lowest contour is 25 feet above the level of the sea, ordnance datum, which is 12 feet 6 inches below Trinity high water The whole of the alluvial flat lying below the lowest contour, or at a less altitude than 12 feet 6 inches above the river Thames (Trinity high water mark), is covered by a dark brown tint.

THE third volume of reports upon the fauna of Liverpool Bay and the neighbouring seas has been issued The reports have been written by members of the Liverpool Marine Biology committee and other naturalists, and edited by Prof W A Herdman, F R S

MESSRS GURNEY AND JACKSON have published the *Zoological Record* for 1891 It is the twenty-eighth volume of the series. Mr D Sharp, F R S, has acted as editor, and has had the co operation of many able zoologists It is intended that in future the volume shall be published in August or September

PHOTOGRAPHERS will read with great interest an admirable paper by Captain Abney, in the November number of the *Journal of the Camera Club*, on "shutters," which he describes as "a piece of apparatus which is the very joy and toy of the photographer's existence" The paper is fully illustrated.

THE Rev L A Walker sends to the current number of the *Entomologist* some statistics of the entomology of the Hague, where he acted as chaplain during July The entomology of Holland seemed to him very disappointing in number of species, and also in individuals in the great majority of cases, less productive, in fact, than the ordinary run of country places at home

AT the meeting of the Linnean Society of New South Wales on September 28, Mr R. Etheridge, junior, exhibited seeds of the "Bean-tree," possibly an *Erythrina*, from Macdonald ranges, Central Australia. The seeds are strong and used as necklaces by the aborigines, who use the wood of the same tree for producing fire by friction, and also for shields, on account of its lightness

A COMPOUND of gold and cadmium of the composition AuCd has been isolated by Messrs Heycock and Neville, and is described by them in the November number of the Journal of the Chemical Society. During the course of a series of experiments last year upon solutions of gold and cadmium in melted tin, it was observed that the amount of lowering of the freezing-point of the tin by the simultaneous introduction of gold and cadmium was considerably less than the sum of the effects which each of the two latter metals would produce alone. It was surmised that this difference must be due to combination between the gold and the cadmium. Moreover, the product o this combination appeared to be only sparingly soluble in tin, for a considerable quantity of a crystalline precipitate was produced, but owing to the difficulty of freeing it from the tin which solidified over it upon removal, the compound was not obtained in a state of sufficient purity to enable a definite conclusion concerning its composition to be arrived at Messrs Heycock and Neville now announce that they have succeeded in preparing the compound in an entirely different manner, and in isolating it in a state of comparative purity The following is the best mode of procedure —A piece of the hardest combustion tubing is sealed at one end and slightly bent in the middle so as to form a V-tube of very large angle A quantity of pure gold is placed in the sealed limb, together with three or four times its equivalent of cadmium The open end is then drawn off so as to enable the tube to be exhausted by means of the Sprengel pump As high a vacuum as possible should be obtained, and the tube subsequently sealed The apparatus is then arranged upon a combustion furnace in such a manner that the excess of cadmium when liquefied may run away from the alloy When the cadmium first melts it is advisable to vigorously shake the tube so as to diffuse the gold well among the cadmium The combination then occurs suddenly, accompanied by bright incandescence of the gold When the larger excess of cadmium has been allowed to run away from the compound, the end of the tube containing the latter is heated for about five hours to a temperature about that of the softening of glass, when the remainder of the excess of cadmium distils regularly off, until towards the expiration of the five hours no further condensation occurs. The product thus left behind was found in three successive experiments to contain about 63 7 per cent of gold, the percentage required for a compound of the composition AuCd The compound of gold and cadmium thus obtained presents a silvery greyish white appearance, is very brittle, and exhibits a crystalline fracture The action of acids upon it is somewhat singular Cold acids appear to be without material action upon it, but hot nitric or hydrochloric acid attacks it with great energy, the cadmium passing into solution and the gold being left in the shape of the original ingot

THE additions to the Zoological Society's Gardens during the past week include a Purple faced Monkey (*Semnopithecus leucoprymnus*) from Ceylon, presented by Mrs Elgee, six Short-tailed Voles (*Arvicola agrestis*) from Scotland, presented by Mr J E Harting, F Z S, two Laughing Kingfishers (*Dacelo gigantea*) from Australia, presented by Mr J W Hornsby, a Golden Eagle (*Aquila chrysaetus*) from Labrador, presented by Mr J. G. Baxter, a Jackdaw (*Corvus monedula*) British, presented by the Rev H. W. Reynolds, three —— Geckos (*Gecko verticillatus*) from Burmah, presented by Mr W G Bligh; two American Darters (*Plotus anhinga*), a Common Boa (*Boa constrictor*) from South America, four Bar tailed Pheasants (*Phasianus reevesi* ♂ ♂ ♀ ♀) from China, purchased.

OUR ASTRONOMICAL COLUMN

A BRIGHT COMET is announced in Andromeda, seventy seconds preceding Struve 72.

COMET BARNARD (OCTOBER 12) —The following is a continuation of the ephemeris we gave last week of Comet Barnard taken from *Astronomische Nachrichten*, No 3125.

Ephemeris for 12h. Berlin M.T.

1892.	R.A. h. m. s.	Decl. ° ′	Log r	Log Δ	Br
Nov 11	20 46 49	+2 33 3			
12	49 40	2 15 7			
13	52 38	1 58·3	0·2262	0 1648	0·97
14	55 25	1 41 2			
15	20 58 19	1 24·4			
16	21 1 14	1 7·9			
17	21 4 9	+0 51·6	0·2250	0·1713	0·94

It may be mentioned that an *Astronomische Nachrichten* circular note contains rather a modified edition of the above places deduced from observations made on October 16, 20, and 25

Thus for the 13th, the R A is given as 20h 54m 24s (app), and declination (app) + 1° 54′ 5 , and for the 17th, R A (app) 21h 6m 39s, and declination (app) + 0° 46′ 4.

COMET BROOKS (AUGUST 28) —Owing to the rapid brightening of Comet Brooks, we give the following ephemeris continued from the same source as mentioned last week (*Astronomische Nachrichten*, No 3125)

12h Berlin M T

1892.	R A app h m s	Decl app ° ′	Log r	Log Δ	Br
Nov 11	9 56 50	+3 18 7			
12	10 1 8	2 24 6	0 0985	9 9861	15 61
13	5 29	1 29 6			
14	9 52	+0 33 8			
15	14 17	−0 22 9			
16	18 45	1 20 3	0 0847	9 9712	17 81
17	23 15	2 18 4			

OCCULTATION OF MARS AND JUPITER BY THE MOON — Prof. Barnard communicates his observations of the occultation of Mars and Jupiter by the moon, which occurred in one week during last September, to the *Astronomical Journal*, No 276 The instrument used was the 12 inch equatorial and the seeing was defined as being very fine on both occasions At the disappearance of the former planet, which took place at the dark limb of the moon, nothing very striking was noticed, the moon's limb at that point being sharp and not dusky, as had been previously seen in an occultation of Jupiter The times of disappearance and appearance (Mount Hamilton mean time) were —

	Disappearance h m s	Reappearance h m s
1st contact	9 9 35 8	10 45 56 0 (1s late ?)
Half obscured	9 10 4	10 26 17
2nd contact	9 10 37 1	10 26 52 2

In the case of Jupiter, which disappeared at the bright limb, a narrow shadow band was noticed fringing the limb where the planet appeared to cut it This is due, as Prof Barnard thinks, to the effect of contrast The times of contacts were as follows —

	Disappearance h m s	Reappearance. h m s
1st contact	17 28 10 4	18 33 17 5 (2s late ?)
Half obscured	17 28 55 0	18 33 50
2nd contact	17 29 45 7	18 34 33 7

MOTION OF THE SOLAR SYSTEM —The question of the exact position of the point in the heavens to which the sun with his system is travelling has been the object of much research and computation, and the present co-ordinates are now considered as being about R A 267° and declination + 31°

The determination under consideration (*Astronomical Journal*, No 276) has been undertaken by Prof J G Porter, and is based on the proper motions of 1340 stars, contained in the Publication of the Cincinnati Observatory, No 12 The method employed for computing the co-ordinates of the apex of the sun's way is that of Prof Schonfeld , the stars were grouped in four divisions, Division I including those whose yearly proper motion was less than 0″ 30 and contained 576 stars ; Division II , motion from 0″ 30 to 0″ 60, containing 533 stars , Division III , motion from 0″ 60 to 1″ 20, containing 142 stars , and lastly, Division IV , the motion exceeding 1″ 20, 70 stars being included From these four groups the following values have been deduced, where σ and τ represent the co ordinates of the apex of the sun's course and $\frac{c}{\rho}$ the velocity of the sun's motion —

	σ °	τ °	$\frac{c}{\rho}$ ″
I	281 9	+51 7	0 16
II.	280 7	+40 1	0·30
III.	285·2	+34·0	0 55
IV.	277·0	+34 9	0 66

The last determination of these co-ordinates was made, if we are not mistaken, by Prof. Stumpe, and were given in *Astronomische Nachrichten*, Nos. 2999–3000. The values there deduced agree very well with those in question, with the exception of τ in Group I and σ in Group IV , which consequently throw the mean values rather out Adopting the same notation, he obtained—

	σ °	τ °	$\frac{c}{\rho}$ ″
I Group	287 4	+42 0	0 140
II ,,	279 7	40 5	0 295
III ,,	287 9	32 1	0 608
IV ,,	285 2	30 4	2 057

Summing up the values obtained by some previous workers, the following table gives the co-ordinates obtained —

Name	R A	Decl	No of stars used in reduction
Gauss	259 2	+30 8	—
Argelander	259 9	32 5	390
O Struve	261 5	37 6	392
Mädler	261 6	39 9	2163
Airy	261 5	24 7	113
Dunkin	263 7	25 0	1167
Kancken	284 6	31 9	106
Birchoff	285 2	48 5	480
L Struve	273 3	27·3	2509
Stumpe	285 1	36 2	1054
Porter	281 2	40 7	1340

SOME REMINISCENCES OF THE MAORIS

MR W COLENSO, F.R S , has often been asked to record some of his reminiscences of the Maoris, whom he has for very many years had opportunities of studying This he has now done in a paper printed in the Transactions of the New Zealand Institute (vol xxiv), some extracts from which may be of interest for various classes of readers He says —

Of the Mako Shark —Fifty years ago (to go no further back) a Maori chief would be known by wearing certain emblems or insignia indicative of rank, one of which was the tooth of the *mako* as an ear pendant ; and, as such were plentiful, though distributed, the thought often occurred to me in my early travelling days, What a number of the fish *mako* there must have been captured or obtained by the Maoris to yield such a large number of teeth ! Moreover, on inquiry I invariably found that all the teeth I saw were prized heirlooms, and had descended to the present possessor through several generations, and (as far as I could learn) none had been recently acquired. And while, when travelling along the sea coasts for many a league on both sides of the North Island during several years, and always on foot, I had both seen and heard of a number of large sea animals (fishes and mammals) that were driven on shore on the sandy beaches in severe gales from the sea, I never knew of a single *mako* shark, nor had the Maoris resident on those shores ever heard of one being cast up

In replying to my numerous inquiries by letter respecting the *mako*, made many years ago, an intelligent aged Maori chief living on the east coast wrote as follows (or, rather, he being of the old school, and unable himself to write, a young adherent did so at his dictation). I give a literal translation of portions of his letter —

"You ask, did I ever see a *mako* fish ? Yes ; and it is a very large creature, the biggest of all the sharks (*mango*)—in length 2 fathoms measured (*erua maro whanganga nei*), and in thickness 1 foot It is a true shark, but called by us a *mako* on account of its teeth. You also inquire concerning its fat or oil, and the edible qualities of its flesh, whether considered choice by us Maoris Now, there are many kinds of shark, as the *mako*, the *karaerae*, the *poke*, the *ururoa*, the *matini*, the *tahapounamu*, the *tatari*, the *tatere*, and the *mangotara*, and I have not eaten of them all, and therefore I do not know how nice or how fat they all are ; and so of this one, the *mako*. But, my friend, this fish was never desired as an article of food—never so used by us Maoris The only part of it that we sought and greatly desired to have was its head, and *this solely* on account of its teeth. When caught out at the deep-sea fishing-grounds its body was never hauled into the canoe, but the head was cut off while it was still in the sea and alongside of the canoe (*ka tapahia moanaia te upoko*) : this done, and the head secured, the body was left to drift away on the sea. The head was also immediately wrapped up securely in a clothing-mat (*kahu*), lest it should be noisily wondered at by those who

were strangers or unacquainted with it (*koi umerehia e nga tangata tauhou*) You also ask what instrument was used for cutting off the head of the *mako* What, indeed! Why, the saw made of the teeth of the *tatere* shark firmly fixed on to a wooden blade (*he niho tatere, he mea hohou ki runga ki te rakau*). You further inquire respecting the number of its teeth There are eight—that is, large ones from within—and also eight smaller ones of them outside. Besides those there were several much smaller ones in front or outside (*o waho rawa*), but these I never counted, and therefore cannot give their exact number"

He also wrote (in another and subsequent letter) in answer to my further inquiries "There are four very large teeth from the beginning, or within These are called *rei*, and are kept for ear-pendants. Altogether there are eight teeth—that is, four very large ones, and four smaller, making eight in all The outside teeth resemble those of the *tatere* shark, and are only termed teeth (*niho*), these have no other name, but those that are kept for ear-pendants are called *au rei* Then, you wish to know how the *mako* was captured by us Maoris in the olden times Listen This fish was never taken as other sharks (*mango*) were, with hook and bait none of our fish hooks would be strong enough to hold it, they would soon be broken Now, when the fishing-canoe was out fishing, and had been a long time there catching fishes of various kinds, suddenly a *mako* would be seen coming leisurely along on the surface of the water (*e hara mai noa ana i te kiri o te wai, ara i te kare o te wai*) Then the man who saw it would shout out to his companions in the canoe, 'Haul up our land' (*Hutia mai to tatou whenua*), not naming the fish, and when the *mako* was pretty near to the canoe, about three yards off, then the big tempting bait was let low down before it, and on the *mako* seeing the bait it would bend down its head to seize it (*ka tupou te upoko*), when its tail would be upraised above water Then a noosed rope would be flung over its tail (lasso-fashion) and quickly hauled tight, which would secure the tail within the noose hard and fast And away would speed the canoe at a fleet rate towards all sides of the sea and sky, being continually turned about in all directions by the fish, the man who had noosed it always holding on to the rope. At last, being exhausted, the *mako* died, then it floated, when its head would be cut off, as I said before This was our common manner of catching the *mako* fish (*ko tona hii tonu tenei o tenei ika o te mako*), often also called by us a monster (*taniwha*), and hence arose the term of monster-binding (*heretaniwha*), owing to it being securely noosed and bound with a rope flung over its tail" Here ends the interesting narration of my worthy old Maori correspondent, who died soon after

I have never seen a *mako* fish, and I am in doubt whether it is yet fully known to science It is evidently one of the deep-water fishes The first mention of it by skilled scientific observers that I have noticed is in Sir James Ross's "Voyage to the South Seas," wherein it is stated that on nearing the Chatham Islands, in November, 1841 (within a week after leaving their winter quarters and anchorage in the Bay of Islands), "the long snouted porpoises were particularly numerous One of these creatures was struck with a harpoon, and in its formidable jaws we found the teeth which the New-Zealanders value highly as ornaments, and which had puzzled us greatly to ascertain to what animal they belonged" (vol ii, p 134) Those Antarctic Expedition ships had spent several months in the Bay of Islands, and the officers had frequent opportunities of seeing and examining the teeth of the *mako*, and very likely had purchased some from the Maoris, as they were diligent in acquiring natural specimens, and curios and ornaments of all kinds.

Professor Hutton, in his "Catalogue of the Fishes of New Zealand" (published by the Government in 1872), considered the *mako* to be the "*Lamna glauca* = tiger-shark," but he says, "The shark from which the Maoris obtain the teeth with which they decorate their ears is probably this species, but I have seen teeth only" (*l.c.*, p. 77)

Subsequently Professor Julius von Haast (in 1874) read a paper before the Philosophical Institute of Canterbury (Trans. N.Z. Inst, vol. vii., p. 237) on the *mako* of the Maoris, which, he says, is *Lamna cornubica*, the porbeagle shark, and not *L. glauca* as had been supposed by Professor Hutton. But Professor von Haast had only a small young specimen (or, rather, its skin) to examine, which two North Island Maoris, then engaged at Christchurch Museum, pronounced to belong to a young *mako*, and informed him that this fish in its adult state was about 12ft long The animal to which the skin belonged was 4ft 10in long Professor von Haast also gives much information relative to the teeth of his small specimen (differing widely from my Maori friend's description given above), their number, form, and size, the colour of its skin, &c Still, as I take it, there are reasonable doubts as to that specimen being a true *mako*, I think it is highly probable that his two Maori informants had never seen a real *mako* shark

Couch, in his celebrated work on "British Fishes," in his account of the porbeagle shark, gives a drawing of it from nature, and also others of its teeth and jaws, which appear to be different from those of the *mako*, being much more slender, and semi-terete, undulate, and sharply pointed (vol i, pp 41-44)

My object in writing this notice of the *mako* shark is mainly to relate the ancient Maori mode of capturing it

Of the Preparation of Black Pigment for Tattooing—The ancient Maoris had more ways than one of obtaining the black substance used in tattooing, which colouring matter also varied in quality, partly owing to what it was made from, that for the countenance being superior to that used for the lower parts of the body One way of obtaining the best kind was as follows —

First, two proper careful men were selected for the work This, too, was done with ceremony, they being (for the time) *tapu* (*i e*, under the laws of *taboo*)—rigidly set apart. A small kiln-like furnace (*ruangarehu*) was excavated in the side of a hill suitably situated The substances to be used in burning for their soot—*kauri*-resin (*kapia*) and the resinous veins of white pine wood (*kapara*)—were got ready, a net made from the *wharanui* flax leaves finely split, composed of very small and close meshes, and beaten well, so as to be rough and scabrous from long broken fibres, in order the better to catch and retain the soot (*awe*), which was intended to adhere only to the network this net was fixed properly and securely over the top opening or chimney of the kiln, and above it were placed thick mats and such like, to prevent the escape of the burning soot and smoke All being ready, a very calm fine night was chosen for the firing of the kiln—a night in which there should not be the least breath of moving air, and, the kiln being fired, those two men remained all night at their post, attending to their work, carefully feeding the fire When all the resinous substances were burnt up, and the kiln cold—the calm weather still continuing—the soot was carefully collected and mixed up with the fat of birds, and then given to a Maori dog to eat, which dog had also been early set apart for this work—tied up, made to fast, and kept hungry, that it might perform its part and eat the prepared morsels with avidity After devouring the mixed food the dog was still kept tied up, and not allowed to eat any other aliment until it had voided the former. When the fæces were evacuated they were carefully gathered, and mixed up and kneaded with bird's oil and a little water, and, when this mixture became dry and hard, it was put up securely into a large shell, or into a hollowed pumice or soft stone, and laid by carefully, buried in the earth, for future use. It is said to have possessed no disagreeable odour when dry (though it had while fresh), and, though long kept, it did not become bad nor spoil through keeping, which, on the contrary, was said to improve it, and it was very much prized

It was this pigment, so put up and kept, that was the origin of one of their proverbs, "*Puritia to ngarahu kauri*" = Keep to thyself thy kauri-resin-soot pigment This saying was used when a person was unwilling to give what was asked, the same being some common thing, and not at all needed by the avaricious owner. But there is a double meaning here in this simple sentence (proverb)—namely, "You may never require it, or live to use it" (See Trans. N Z. Inst, vol xii., p 145)

Of the Manufacture of their Long Spears—Some of their spears were very long Of these there were two kinds One kind was made of hardwood, *rimu* (*Dacrydium cupressinum*) This was used in defending their forts and stockades before the introduction of firearms, being thrust through the palisades at close quarters against the legs and bodies of the invaders. The other kind was much lighter, though longer, being made of the light wood of the *tawa*-tree (*Beilschmiedia tawa*), and used only for the spearing of pigeons when they were sitting on the top of a high tree. This spear was tipped with a flattish serrated bone 3 inches—5 inches long, usually coarsely barbed on one lateral edge, and sharply pointed; the bone being human, and a portion of that of the arm or leg, and, of course, of their

deadly enemies Seeing that these long spears were always made from heartwood of their tallest trees, it was a mystery to me how they managed to manufacture them, the hardwood ones being from 16 feet to 20 feet and the others from 20 feet to 35 feet long, and it was not until my first visit to the Urewera Tribe, at Ruatahuna, in the interior beyond Waikare Moana, in 1841, that I discovered how it was effected This patient performance has ever seemed to me a notable example of one of their many laborious and persevering works For it must never be forgotten, in considering their ancient laborious and heavy works, especially in hard substances, as wood, bone, and stone, that they accomplished all without the use or knowledge of iron or any other metal

First, a straight, tall, and sound *tawa*-tree was selected in the forest This was felled with their stone axes Its head and branches having been lopped off, it was dragged out into the open ground, and split down the middle into two halves If it split easily and straight, then it would probably serve for two spears, if each half turned out well in the working The next thing was to prepare a long raised bed of hard tramped and beaten clay, 35ft 40ft long—longer than the intended spear—the surface to be made quite regular and smooth (like a good asphalte kerb town walk of the present day) On to this clay bed the half of the *tawa* tree was dragged, and carefully adzed down by degrees, and at various times, to the required size and thickness of the spear It was not constantly worked, but it was continually being turned and fixed by pegs in the ground, to keep it lest it should warp and so become crooked It took a considerable time—about two years—to finish a spear The last operation was that of scraping with a broken shell or fragment of obsidian, and rubbing smooth with pumice-stone When quite finished and ready for use a suitable tall and straight tree was found in, or on the edge of, the forest, its trunk was trimmed of branchlets, &c, the long spear was loosely fixed vertically to it, so as to run easily through small round horizontal loops girt to the tree, and placed at some distance from each other, the tip of the spear concealed, yet protruding near the topmost branches of the tree, and, as the pigeon is a very thirsty bird (especially, I should think, after feeding on the large fruits of the *tawa* and of the *miro*—*Podocarpus ferruginea*—trees, which are hot and piquant), the Maoris made small corrugated vessels of the green bark of the *totara* tree that would hold water, and fixed such on the top of the tree to which the long spear had been lashed, and by-and by, when the bird was settled above after drinking (for it is a very quiet bird, sitting long after feeding), the spear was gently pulled down by its owner below on the ground, and sent up with a jerk into the body of the pigeon I have seen the fixed spear thus used in the forests, and have eaten the bird so captured

I may here mention that I have also seen those totara-bark dishes, with water in them, fixed high up on the big branches of trees in the woods in the Urewera country, having flax nooses so set over the water as to catch and hold fast the pigeon in its drinking I have seen pigeons so caught, the Maoris climbing the trees naked with the agility of monkeys to secure their prizes

From the large amount of labour and the time consumed in the making of a long spear, and its great beneficial use when made, arose a good proverb among them relative to industry in tillage, &c., and to being prepared—"*Kahore he taranga tahere i te ara*" = You cannot hew a bird-spear by the way Meaning Without timely preparation you may die from want of food, though the pigeons are plentiful in the forests near you

Of the Fine Smelling-sense and Taste of the Ancient Maoris for Perfumes.—I have already more than once, and in former papers read here before the Institute, touched on the superior powers of sight of the ancient Maoris,[1] and it has often occurred to my mind that they also possessed a very keenly developed sense of smell, which was largely and quickly shown whenever anything sweetly odoriferous, however fine and subtle, had been used—as eau de Cologne, essence of lavender, &c Indeed, this sense was the more clearly exhibited in the use of their own native perfumes, all highly odorous and collected with labour Yet this sensitive organization always appeared to be the more strange when the horribly stinking smells of two of their common articles of food—often, in the olden times, in daily use—are considered rotten corn (maize, dry and hard, on the cob) long steeped in water to soften it, and dried shark. The former, however, has long been abandoned, yet at one period every village at the North had its steeping-pit

In a paper I read here at our June meeting I mentioned some of the very small Hepaticæ (*Lophocolea* and *Chiloscyphus* species) as being used for perfume by the Maoris, who called them *piripiri* Their scent was pleasant, powerful, and lasting Hooker, in describing those plants, has mentioned it from dried and old specimens Of one species, *Lophocolea pallida*, he says, "odour sweet," of another, *L novæzealandiæ*, "often fragrant," of another, *L allodonta*, "odour strong, aromatic," of another, *Chiloscyphus fissistipus*, "a handsome strongly-scented species" and he has further preserved it to one of them in its specific name, *C piperitus*, "odour of black pepper"

There were also two or three ferns—viz, *Hymenophyllum sanguinolentum*, a very strong smelling species, hence too its specific name, dried specimens not only retain their powerful odour, but impart it to the drying papers *Polypodium pustulatum*, having an agreeable delicate scent and *Doodia fragrans*, a neat little species, this last was so far esteemed as sometimes to give name to the locality where it grew, as *Puke mokimoki*,[1] the little isolated hill which once stood where the Recreation ground now is in Napier, that hill having been levelled to fill in the deep middle swamp in Monroe Street

One of the *Pittosporum* trees, *tawhiri* (*P tenuifolium*), also yielded a fragrant gum, but the choicest and the rarest was obtained from the peculiar plant *taramea* (*Aciphylla colensoi*), which inhabits the alpine zone, and which I have only met with near the summits of the Ruahine Mountain-range, where it is very common and very troublesome to the traveller that way The gum of this plant was only collected through much labour, toil, and difficulty, accompanied, too, with certain ceremonial (*taboo*) observances An old *tohunga* (skilled man, and priest) once informed me that the *taramea* gum could only be got by very young women—virgins, and by them only after certain prayers, charms, &c, duly said by the *tohunga*

There is a sweet little nursery song of endearment, expressive of much love, containing the names of all four of their perfumes, which I have not unfrequently heard affectionately and soothingly sung by a Maori mother to her child while nursing and fondling it —

Taku hei piripiri,
Taku hei mokimoki,
Taku hei tawhiri,
Taku kati taramea.

My little neck-satchel of sweet-scented moss,
My little neck-satchel of fragrant fern,
My little neck-satchel of odoriferous gum
My sweet smelling neck locket of sharp-pointed *taramea*.[2]

Here I may observe that to the last one of the four the word *kati* is prefixed this word—meaning, to sting, to bite, to puncture, to wound sharply and painfully—is added to indicate the excessive sharpness of the numerous leaves and leaflets of the *taramea* plant (hence judiciously generically named by its early discoverer, Forster, *Aciphylla* = needle pointed leaf), and the consequent pains, with loss of blood, attending the collecting of its prized gum, thus enhancing its value

This natural and agreeable little stanza, one of the olden time, has proved so generally taking to the Maori people that it has passed into a proverbial saying, and is often used, hummed, to express delight and satisfaction—pleasurable feelings And sometimes, when it has been so quietly and privately sung in a low voice, I have known a whole company of grey headed Maoris, men and women, to join in the singing · to me, such was always indicative of an affectionate and simple heart How true it is, "One touch of nature makes the whole world kin"![3]

In the summer season the sleeping-houses of their chiefs were often strewed with the large sweet-scented flowering grass *karetu* (*Hierochloe redolens*) Its odour when fresh, confined in a small house, was always to me too powerful[4]

[1] Trans N Z Inst vol xiv p 67, &c.

[1] Mokimoki Hill, from *mokimoki*, the name of that fern

[2] See Trans N Z Inst., vol. xii, p 148

[3] It is pleasing to notice that the observant artist Parkinson (who was with Sir Joseph Banks as his botanical draughtsman, and Cook on his *first* voyage to New Zealand) makes special mention of those little satchels in his Journal, saying of these Maoris who came off to the ship in their canoes, "The principals among them had their hair tied up on the crown of their heads with some feathers, and a little bundle of perfume hung about their necks" (Journal, p 93) Captain Cook, also, has similar remarks respecting the young women.

[4] Sir J. D. Hooker thus writes of this fine, sweet-smelling grass in his "Flora Novæ Zelandiæ" "A large and handsome grass conspicuous for its delicious odour, like that of the common vernal grass (*Anthoxanthum*) of England, that gives the sweet scent to new-made hay" (*l c*, vol ii, p. 300). A closely-allied northern species (*H borealis*), which was also supposed to

Here, in conclusion, I may briefly mention an instance of their correct discrimination on the contrary side, clearly showing how well and closely the ancient New-Zealander agreed in his opinion of a plant with the highly civilized scientific visitor already named above, the botanist Forster. Forster named the *Coprosma* genus from the fetid odour of the first species he discovered in the South Island, which signification he also continued in its specific name, *C. fœtidissima*: this shrub also bears a similar Maori name, *hupiro*, highly expressive of its very disagreeable smell.

Of their Textile Manufactures.—These were formerly prominent among the great industrial achievements of the Maoris, and always elicited the admiration of their wondering visitors.

I divide them into two great classes—(1) of garments, which were woven; and (2) of threads, cords, lines, and ropes, which were spun.

Nature had given to the Maoris one of her choicest gifts in the well known flax plant (*Phormium*), of which there are two ascertained and valid species (*P. tenax* and *P. colensoi*), and several varieties. These plants are pretty general throughout New Zealand, and are well known to the Maoris by the common names of *harakeke*, *wharanui*, *wharariki*, and *tihore*—excluding those of the many varieties as known to them.[1] So that what they may have lost on the one hand through not having the valuable wild edible fruits of other South Sea Islands (as the cocoanut, bread fruit, plantain, &c.) they more than merely gained in their flax plant, which is also common, and almost endemic, being only found outside New Zealand in Norfolk Island.

And here I may briefly mention an anecdote of the flax plant. On my arrival in this country the Maoris (who knew nothing, or very little, of any other land) would often inquire after the vegetable productions of England; and nothing astonished them more than to be told there was no *harakeke* growing there. On more than one occasion I have heard chiefs say, "How is it possible to live there without it?" also, "I would not dwell in such a land as that." This serves to show how highly they valued it. Moreover, at first and for many years the principal export from New Zealand prepared by the Maoris was the fibre of this plant—all, too, scraped with a broken shell, leaf by leaf.

1. *Of their Woven Articles (or Garments).*—I do not intend to say much of them in this paper. Many of them are well known, and still to be found in use among the Maoris, but their manufacture has for many years sadly deteriorated: indeed, I have not seen a newly-made first quality clothing mat for the last twenty to thirty years, and I very much doubt if such can now be made at all. Not that the art of weaving them has been entirely lost, but the requisite taste, skill, and patience in seeking and carefully preparing and using the several parts (including their dyes) are no longer to be found among the Maoris. I sometimes indulge in a contemplating reminiscence—an idea—a pleasing reverie of the long past—of great gatherings of Maoris, tribes and chiefs; and at such times the figures of some head men I have known, clothed in their handsome, clean, and lustrous dress-mats (*kaitaka* and *aronui*), would stand forth in pleasing high relief. The close and regular weaving of such flax dresses, having their silky threads carefully selected as to fineness and uniformity of colour, and their smooth, almost satiny appearance, as if ironed or calendered when worn new, was to me a matter of great satisfaction—a thing to be remembered—"a joy for ever."

Those best dress-mats were always highly prized, both by Maoris and Europeans, and brought a high price. I well recollect a young lady, daughter of very respectable early English settlers in the Bay of Islands, who, when she came across the inner harbour in a boat with her parents to attend the English Church service on Sunday mornings in the Mission chapel at Paihia, often wore one of them folded as a shawl, and to me it seemed a neat and graceful article of dress.

Three things more in connection with these fine mats I will just relate: one, the cross-threads in weaving were always of a different sort of flax—the weft and the woof of these mats were not both taken from the same kind of flax; the second, that extremely soft lustrous appearance was given to the flax fibres by repeated tawing done at different times—it was a pretty sight to see the various skeins of flax fibres in their several stages of preparation neatly hung up in the weaving shed; the third, that in the weaving of one of these garments, if a thread showed itself of a different shade of colour, that part of the garment was carefully unravelled to take it out, and to substitute another better suited in its stead. It was also from this superior knowledge and close attention to their work that the principal chiefs frequently took women who were clever at making those things to be their wives, in order to secure to themselves their valued manufactures.

They also wove very good and useful floor and bed-mats of unscraped flax-leaves, split into narrow lengths and carefully bleached in the sun—these were very strong and lasting; also baskets and kits of all sizes. Some of them were woven in regular patterns with black (dyed) and uncoloured flax; others were skilfully and pleasingly semi damasked (if I may so term it) by changing sides to the flax leaves used to form the pattern, the upper side of the leaf being smooth and shining, the under side not shining and of a glaucous colour. The little kit, or basket, for a first-born child was often a little gem of weaving art, and made by the mother.

Besides the flax plant they had other fibrous plants whose leaves and fibres were also used in making articles of dress: (1) the *toii* (*Cordyline indivisa*), of which they made black everlasting wraps or cloaks. The making of these was confined to the natives of the mountainous interior, where alone those plants grow. (2) The long orange-coloured leaves of the *pingao* (*Desmoschœnus spiralis*), a prostrate spreading sea side plant, also afforded them good materials for weaving useful folded belts, which were strong and looked and wore well, and were highly valued. (3) The climbing *kiekie* (*Freycinetia banksii*) was also used; likewise the long, slender, and soft leaves of the *kahakaha* (*Astelia banksii*), but not frequently. (4) Of the leaves of the common swamp plant *raupo* = bulrush (*Typha angustifolia*), they formed large sails for their canoes. These leaves the Maoris curiously laced together. (5) I should not omit to mention their flying kites (*pakaukau* and *manuaute*), formerly in great esteem among them, and made of the manufactured bark of the *aute* shrub = paper mulberry (*Broussonetia papyrifera*), which was formerly cultivated by the ancient Maoris for its bark. Inferior ones, however, were made of the prepared leaves of some of the larger sedges. They were prettily made, requiring both time and skill in their construction, and much more resembled a bird flying than our English ones. They always served to remind me of those of the Chinese, as we see them in their own drawings and on their chinaware. The old chiefs would sometimes quietly spend hours amusing themselves in flying them and singing (*sotto voce*) the kite's song, using a very long string.[1] Kites being flown at any village or fort was a sure sign of peace. These, too, gave rise to proverbs, some being quaint and highly expressive. A pleasing one I give as a sample: "*He manuaute e taea te whakahoro*" = A flying kite made of paper-mulberry bark can be made to fly fast (away, by lengthening the cord). Used by a lover, expressive of impatience at not being able to get away to see the beloved one.

2. *Of their Spun Fibrous Articles.*—These were very numerous in kind, size, and quality, according to the particular use for which they were required; and, while the larger number of them were composed of scraped and prepared flax-fibres there were also other fibrous leaved plants used by the Maoris, particularly the leaves of the erect cabbage-tree = *ti* (*Cordyline australis*) and of the *kiekie*, already mentioned. Here, too, in this department, the different kinds of varieties of the flax would be used for making the different sorts of threads, cords, and ropes, some of the varieties of flax enduring much greater strain when scraped and spun into lines than others; and of such their deep-sea fishing-lines were made. It was ever to me an interesting sight to see an old chief diligently spinning such lines and cords—always done by hand, and on his bare thigh. The dexterity and rapidity with which he produced his long hanks and coils of twine and cord, keeping them regular, too, as to thickness, was truly wonderful. Some of their smallest twisted cords or threads were very fine. Such were used for binding on the barbs to their fishing hooks, and for binding the long queues of

---

be found here in New Zealand, is also used on the Continent of Europe for similar purposes. In some parts of Germany it is dedicated to the Virgin Mary (hence, too, its generic name of *Hierochloe* = sacred grass), and is strewed before the doors of the churches on festival days as the *sweet sedge* (*Acorus calamus*) is strewed on the floor of the cathedral at Norwich for the same purpose at such seasons.

[1] Sir James Hector, in his book on the *Phormium* plants, enumerates fifty five named varieties, but it is doubtful whether more than half of that number are permanent ones.

[1] See an interesting historical tradition respecting such (Trans. N.Z. Inst., vol. xiii., p. 48).

dog's hair to their chiefs' staffs. One of those peculiar cords was a very remarkable one; it was a small cord, bound closely round throughout its whole length with a much smaller one (something like the silver or fourth string of a violin). I never saw this kind but once, and that was at the East Cape, in 1838. A specimen of it I shall now exhibit. This cord was used for a single and particular purpose, attached to the small under aprons of girls—chiefs' daughters.

Their larger cords and ropes were composed of several strands, well twisted and put together. Besides their round ropes so made, they had also flat ones of various widths, which were plaited or woven, resembling our webs and bands, and much used as shoulder straps in carrying back loads; also double twisted ropes, and three strand ones; likewise a remarkably strong one that was four sided. This was made of the unscraped leaves of the cabbage tree, that had been gathered, and carefully wilted in the shade, and then soaked in water to make them pliant. It was used for their anchors, and other heavy canoe and house requirements. The leaves of the flax would not be suitable for this purpose. I have had all those different kinds of cords and ropes made for me in former years, but I much fear the art of making them is lost.

There were also their nets for catching fish and for other purposes, with their meshes of various dimensions. Their smaller ones (hand nets) were made of all manner of shapes and sizes. Some of them were dexterously stretched over circular skeleton framework. And their large seine-nets, used for catching mackerel and other summer fish that swam in shoals, were very long and very strong, made of the leaves of flax, split and prepared, but not scraped, and completely fitted up with floats, and sinkers, and ropes, and other needful appurtenances. Cook, who was astonished at their length, has written much in praise of them. I make one striking quotation: "When we showed the natives our seine, which is such as the King's ships are generally furnished with, they laughed at it, and in triumph produced their own, which was indeed of an enormous size, and made of a kind of grass [*Phormium*] which is very strong. It was five fathoms deep, and by the room it took up could not be less than three or four hundred fathoms long."[1] (Voyages, vol. ii., first voyage, pp. 369, 370.)

In residing at Dannevirke, in the Forty-mile Bush district, during several months, I have often noticed the Maoris from neighbouring villages coming to the stores there to purchase tether and other ropes and lines (large and small) for their use with their horses, ploughs, carts, pigs, &c., while on their own lands and close to them the flax plants grew in abundance. These Maoris had very little to occupy their time, and could easily have made common lines and ropes for their own use if they knew how to spin them as their fathers did, and also possessed their forefathers' love of work.

UGANDA

AT a special meeting of the Royal Geographical Society on the evening of November 3, Captain F. D. Lugard gave an account of the geographical aspects of his work in Uganda. The hall of the University of London was crowded, and although the issue of extra tickets was suspended, a large number of Fellows and their friends failed to get admittance. An excellent hand-map, by Mr. Ravenstein, enabled the audience to follow Captain Lugard's route. The first part of the paper was concerned with the journey from Mombasa along the Sabakhi river, an unnavigable stream, to Machako, the furthest station of the I. B. E. A. Company at that time, the district passed through being almost uninhabited, and supplies difficult to procure. The greater part of the paper related to Uganda and the other countries surrounding the Victoria Nyanza, where Captain Lugard was in command for two years. On the Kavirondo plateau, east of the lake, there is a promising field for European colonisation. The plateau is crossed by the Equator, but at elevations of from 7000 to 8000 feet the climate is cool and exhilarating. It is possible, judging from experience in other places, that highlands close to the Equator are healthier for Europeans than those of similar mean climate lying nearer the tropics. Kavirondo is admirably adapted for grazing, and ranches similar to those of the west of America might be tried. From the pasture lands of this plateau the transition to the rich plantations of bananas and casava of Usoga and Uganda is very marked, and the unclothed natives of Kavirondo give place to the comfortably-dressed Waganda, a warlike people, but skilful in all the arts of peace.

Uganda is a land of low hills and valleys. The hills are of red marl, or marl gravel, and shale, generally covered with pasture grass of a kind apparently peculiar to these countries. The valleys are generally of rich black soil, and most frequently the lowest part of the dip is a river swamp. The swamp varies from a few score of yards to a mile or more in breadth, usually being from half to three quarters of a mile. There is a slight trickling current—but very slight; the river is choked with dense papyrus, with an undergrowth of marsh ferns, grass, reeds, &c. The water is usually the colour of coffee, and red with iron rust. Most of these swamps are of treacherous quagmire without bottom; and unless the roots of the papyrus form a sufficient foothold it is necessary to cut down reeds and boughs of trees to effect a crossing. It is a singular characteristic of these countries that, spite of their altitude and hilly character, rushing water is rarely, almost never, to be seen. Thus Uganda has a mean elevation of some 4200 feet, and borders the trough of the Victoria Nyanza at 3700 feet only, and is a country full of hills and valleys. Kitagwenda, at about the same altitude, borders the Albert Edward Lake at 3300 feet. Unyoro, with more lofty hills and peaks of granite, with an altitude gradually increasing in the south, as you near the Albert Lake, to some 5300 feet, similarly borders the trough of the Albert, which has an elevation of only 2000 feet. Yet nowhere are these river swamps more frequent than here in South Unyoro at the highest altitudes. The origin of the water to supply the enormous Lake Victoria is an interesting problem. Throughout the British sphere, on the north and west of the lake, there is no single river, except the Nzoia, which is worthy of the name flowing into the Victoria. The Katonga—marked on the maps as a big river—is merely a broad papyrus swamp. It is by no means so important a drainage as the Marengo; and all the endless river-swamps (including the Marengo) send their sluggish streams northwards to the Kafur and the Somerset Nile. The superficial area of the Victoria being 27,000 square miles, crossed by the Equator, and at an altitude of about 3800 feet, an enormous amount of evaporation must occur, and yet spite of this evaporation, there issues from its north-western corner the magnificent Somerset Nile, a deep, broad, silent river.

The close of the year 1891 and the early part of 1892 were exceptional in the matter of rainfall. Usually in this part of Africa the lesser rains begin early in October and cease in the middle of December. From that time the heat and drought increase, and the grass dries up and is burnt, till in the beginning of March the greater rains set in, and a tropical downpour continues with few breaks till the end of May. Last October and November the lesser rains were unusually heavy, and continued with little intermission till the time of the regular rains in March. There was a little check, and then the rain continued up to the middle of June and later. The result was, that the Lake Victoria was some six feet perhaps above its ordinary level, and may probably rise still higher. Unusual floods occurred in the Nile in Egypt during September, this not being the time at which the usual high Nile due to the Atbara floods occurs.

Uganda is divided into ten provinces, and the ten chiefs who rule these districts entirely drop their personal names, and are called by the traditional title attached to those provinces. Of these the four largest and most important have separate titles. Thus, the chief of Chagwe is the Sekibobo; of Singo, the Mukwenda; of Buddu, the Pokino; and of Bulamwezi, the Kangao. The remaining six are called by the title of their province, viz. Kitunzi, Katambala, Kasuju, Mugema, Kago, and Kaima. Superior in rank to these ten governors of provinces are the Katikiro (the vizier and chief magistrate of Uganda), and the Kimbugwe. These two hold innumerable estates, scattered throughout the country.

In June, 1891, Captain Lugard left Uganda with the object of coming in touch with the Soudanese refugees from the Equatorial Province, who had assembled at Kavalli's, on the south-

[1] An interesting historical tragic story of the cleverly-planned taking and death of a large number of Maoris in one of these seine-nets, together with the fish (illustrating what Cook has written of their immense size), and of the deadly warfare that followed, is given in the Transactions N.Z. Institute vol. xiii., p. 43.

west shore of the Albert Lake Marching from near Masaka, the capital of Buddu, he traversed Northern Ankole, a district hitherto unvisited by any European, though Mr Stanley, in 1876, had travelled parallel to it within the boundaries of Uganda, and reaching the borders of Kitagwenda, proceeded south-west to the narrow channel or river which connects the upper lake of Rusango with the main waters of the Albert Edward Lake Crossing this narrow channel (at most 500 yards wide) the force camped in the hostile country of the Wasura, a tribe subject to Kabarega of Unyoro, and identified with the Wanyora. Here they crossed Mr Stanley's route at the Salt Lake; but since his book nor maps had not then reached Central Africa the journey was in the nature of entirely new exploration, though of course the discovery of the Albert Edward Lake and of Ruwenzori had been anticipated. The natives, too, being hostile, no one was met with who had seen Mr Stanley, or could give information of his route, or tell of his exploits On the route to the Albert Lake many deep and almost symmetrically circular depressions like the crater of a volcano, or a dried up pond, were passed A few of these, as shown on the map, were tiny lakes no bigger than a mill-pond, but apparently of great depth, with clear blue water, and all the characteristics of a lake The alligator and great fish eagle haunted their waters Others, again, were dry, the bottoms being perhaps 100 feet or more below the level of the surrounding country, which is about 4200 feet above the sea.

The Lake Albert Edward consists of two portions, the Mwutan-zigé (Barrier to Locusts), or the Great Lake and the Rusango on the north east This latter is in reality a separate lake, connected with Mwutan-zigé by a river Its general direction is north-west and south-east There is no swamp around it except at the north west end, where dense jungle and impenetrable marsh afford a home for great herds of elephant. It is at this point that the rivers Wami and Mpanga, into which the countless streams from Ruwenzori flow, bring their waters to the lake The gorge through which the latter flows is picturesque in the extreme, especially in the rains. The great body of water confined between its rocky walls boils and eddies over the sunken rocks below The gorge is some 700 feet deep, and is full of tropical forest The orchids, ferns, and mosses which are found in such a natural forcing-house, where the damp vapours hang, are extremely luxuriant

Captain Lugard followed the eastern base of the Ruwenzori Mountain, crossing the endless streams which descend from its perpetual snows, and hear their clear, sparkling, icy-cold water to the Wami and Mpanga, and so to the Albert Edward The drainage of the eastern Ruwenzori is not towards the Albert and so to the Nile, but to the southern lake, from which the only overflow is the Semliki, a river which at its exit probably conveys a lesser volume of water from the Lake than is contributed to it by the Mpanga alone The ground rises gradually from the level of the Albert Edward 3300 feet to some 5300 feet at Kiaya. Here the route descends into the head of a narrow valley, while the plateau trends away to the right, and forms the uplands of Unyoro, its bold outline appearing from the Semliki Valley and the Albert Lake like a lofty range of hills The valley of Kiaya is extremely fertile, intersected with streams, and studded with banana groves and cultivated land. Between the edge of the plateau on the east and the base of Ruwenzori there is a deep trough, or gorge, the hills rising steep as it were from their own foundations without connection with the plateau, which reaches to their very feet Leaving Kiaya, they passed through a wild country of quartz and scrub jungle, cut at right-angles by gigantic ravines of rich soil, in which are villages, forest, and cultivation This led to the edge of a lower plateau, overlooking the Semliki valley Simultaneously the massive peaks of Ruwenzori sloped down to lesser hills, and mingled with the plain, and a new range of mountains, increasing in height from south to north, appeared opposite Mountains they appear, but, like those left behind, they are really the escarpment of the plateaus on which the sources of the Ituri, and the other great affluents of the Congo, take their rise, which, for convenience, may be called the Kavalli plateau. From Kavalli's Captain Lugard escorted 8000 Soudanese troops, who had by their vacillation retarded the departure of Stanley with Emin for the coast Some of these he settled in forts to protect Uganda from Kabrega's raiders, while others were sent back to Egypt by Mombasa.

SCIENTIFIC SERIALS

American Meteorological Journal, October —A meteorological balloon ascent at Berlin by A L. Rotch The ascent was made on the morning of October 24, 1891, and at the same time a captive balloon was sent up to 600 metres The weather was hazy up to about 1000 feet, but above that the sky was nearly clear The mean decrease of temperature between the ground and the captive balloon was 0°6 C. per 100 metres. In the stratum of air between the captive and free balloon (700 to 1000 metres) the decrease was much slower during the morning, there being at first an increase, the temperature at 693 metres was 10° C, and at 858 metres 10°4. In the afternoon the rate of decrease in the upper stratum became nearly the same as that which prevailed in the lower stratum during the morning —Improvement of weather forecasts, by Prof H A Hazen The author recommends the study of moisture conditions at various heights in the atmosphere, and considers that the greatest hope of improvement is in the observation of atmospheric electricity —The storms of India, by S M Ballou. The storms are divided into three classes (1) the cyclones that occur at the changes of the monsoons, (2) the storms of the summer rains, (3) the winter rains of the northern provinces, he discusses the causes of their formation, and gives a brief description of each of these classes —The ether and its relation to the aurora, by E A Beals The author gives a brief summary of some of the facts respecting our knowledge of auroras, in view of their probable maximum during the coming year in connection with their correlation with frequency of sunspots — There are also short articles on warm and cold seasons, by H. Gawthrop, facts about rain making, by G E. Curtis, and convectional whirls, by Prof H A Hazen

SOCIETIES AND ACADEMIES

LONDON

Anthropological Institute, October 18 —A special meeting was held, the president, Edward B Tylor, D C.L, F R S, in the chair, to receive a communication from Major R C Temple, I S C, on "Developments in Buddhist Architecture and Symbolism as illustrated by the Author's Recent Exploration of Caves in Burma" Major Temple commenced by saying that the object of the paper was chiefly to draw attention to the extraordinarily rich and for the present practically untouched field for the ethnographist and antiquary existing in Burma He exhibited some photographs of life size figures in wood, carved by a well known artist of Maulmain, of the "four sights" shown to Buddha as Prince Siddhartha on his first visits to the outer world, viz., the old man, the sick man, the dead man, and the priest; and also some admirable gilt wooden representations from Rangoon of Buddha in his standing and recumbent postures, with his begging bowl, and seated as King Jambupati, surrounded by priests and other worshippers He next showed a remarkable set of gilt wooden images from the platform of the great Shwedagon pagoda at Rangoon, of *nats*, *belus*, *hanuman myauks*, and other spirits believed in by the Burmese, seated on the steps of a lofty *tagon-dain*, or post, on the top of which is always perched the figure of the hentha (hansu), or sacred goose, which apparently protects pagodas in some way From these he passed on to four representations of large glazed bricks or tiles from Pegu These curious, and (so far as English museums are concerned) probably unique antiquities may be presumed to be at least 400 years old, and formed at one time the ornamentation of the three procession paths round a now completely ruined pagoda. They represent the march, battle, and flight of some foreign army, represented in true Indian fashion with elephant, monkey, and other animal faces. Some of the figures are clad in Siamese and Cambodian fashion The glazing is remarkably good, and Indian influence is clear in their construction They may probably represent a scene from the *Ramayana*, which in a mutilated form is well known to Burmese mythology These were followed by a huge figure of Buddha from Pegu, in his recumbent attitude, which may be referred to King Dhammacheti, who flourished in the fifteenth century. This image is 181 feet long and 46 feet high at the shoulder. It is built of brick, and is well proportioned throughout. Its history is lost, and so was the image itself until 1881. Pegu was utterly destroyed about 1760 by the Burmese,

and the interest in its holy places lost for more than a generation This image became jungle grown and hidden from view, and was accidentally discovered by a railway contractor searching for ballast for the line in the neighbourhood General and detailed views of the Kawgun Cave were shown, exhibiting the wonderful extent of its decoration by a vast number of terra cotta tablets and images in wood, marble, alabaster, and other materials, and the extraordinary variety and multitude of the objects connected with Buddhistic worship, both ancient and modern, to be found in it The Kawgun Cave is the richest of those visited by Major Temple, but he explained that he had examined about half a dozen others in the district, and had since gathered positive information from local native sources of the existence of about forty altogether Many of these are hardly inferior to Kawgun in richness of Buddhistic remains, and several are said to contain in addition ancient MSS, which must now be of inestimable value A few such MSS have actually been found It will thus be seen how great and valuable is the field, and how well worth systematic study by competent students

Royal Microscopical Society, October 19 —Mr G C. Karop, Vice president, in the chair —The chairman exhibited and described Messrs Swift's aluminium microscope, which he believed to be the first microscope made of that metal The chief point in the instrument was its extreme lightness, the whole when complete, and including the condenser and eyepiece, weighing only 2lb 10½oz as against the weight 7lb 13oz of a precisely similar stand made in the usual way of brass It was perhaps not entirely correct to say that every portion was of aluminium, because there were certain mechanical difficulties met with which prevented some portions from being made of that metal, for instance, he believed it was almost impossible to cut a fine screw upon it without the thread "stripping," and it was also found extremely difficult to solder, so that the necessary screws in the instrument were made of brass, the Campbell fine adjustment of steel, the rack and pinion coarse adjustment was also not made of aluminium, and the nose piece was of German silver —Prof F Jeffrey Bell read a letter received from Mr H G A Wright, of Sydney, stating that a scale of Podura in his possession was deeply notched, and that an exclamation mark had become detached and projected from the edge Mr Wright also sent photomicrographs to support his statement The chairman said he could not be sure, from the cursory examination he had been able to make, that the exclamation mark referred to was to be seen —Dr C E Beevor read a paper on methods of staining medullated nerve-fibres, illustrating the subject by photomicrographs, and by a number of preparations under microscopes The chairman said they were very much indebted to Dr Beevor for his interesting paper It was a good thing to be able to differentiate nerve fibres in the ways described, but it was a pity that they could not also so differentiate them as to show from which part of the nervous system they came If this could be done he need hardly say it would be of great value —Prof Bell read a paper by Dr H G Piffard on the use of monochromatic yellow light in photomicrography Mr. T Charters White said that he had himself tried a similar process with monochromatic light obtained by using screens and solutions, but the chief difference he found was that it very much prolonged the time necessary for exposure Mr T. Haughton Gill said that he had used the copper light filter for the same purpose, and had found that by its aid any good ordinary lens would give as good results as were otherwise obtained by using an expensive apochromatic, because it filtered off all the rays except those which were visually strong He had not found, in the course of his work, that the use of this light prolonged the exposure, that was to say, that with a magnifying power of ×300 and an exposure of ten minutes, he could get a good strong printing image with the isochromatic plates —Mr G Massee's paper on *Heterosporium asperatum*, a parasitic fungus, was, in the absence of the author, taken as read

Entomological Society, November 2, Frederick DuCane Godman, F.R S, president, in the chair —Mr. S Stevens exhibited, for Mr J Harrison, a beautiful series of *Arctia lubricipeda* var. *radiata*, which had been bred by Mr Harrison this year.—Mr G. T. Bethune-Baker exhibited specimens of *Polyommatus dispar* var. *rutilus*, taken in England by his father about sixty years ago He stated that it was generally believed that this form of the species was confined to the Continent, but his specimens proved that it formerly occurred in England.—Mr. C G. Barrett exhibited dark varieties of *Acronycta leporina*, bred by Mr J Collins also a white variety of *Triphæna pronuba*, taken at Swansea.—Mr M Jacoby exhibited a specimen of *Sagra femorata*, from India, with differently sculptured elytra, one being rough and the other smooth —Mr J A Clark exhibited a long series of remarkable varieties of *Liparis monacha*, bred from two specimens taken at Scarborough Several of the specimens were as light in colour as the typical form of the species, others were quite black, and others intermediate between these two extremes —The Rev Seymour St John exhibited a monstrosity of *Abraxas grossulariata*, and a specimen of *Tæniocampa stabilis*, with a distinct light band bordering the hind margin of the upper wings —Mr. E B Poulton, F R S, exhibited two series of imagos of *Gnophos obscurata*, which had been subjected to dark and light surroundings respectively The results were seen to be completely negative, the two series being equally light —Mr F Merrifield showed a number of pupæ of *Pieris napi* About eight of them, which had attached themselves to the leaves of the cabbage plant on which they were fed, were of a uniform bright green colour, with light yellowish edgings, of the others, those which had attached themselves to the black net covering the pot, or the brownish twigs which supported it, were dark coloured, with dark spots and lines Mr R Adkin exhibited three bred female specimens of *Vanessa c album*, two of which belonged to the first brood, and the third to the second brood One of the specimens of the first brood was remarkable in having the under side of a very dark colour, identical with typical specimens of the second brood He thought the peculiarity of colouring had been caused by a retarded emergence, due to low temperature and absence of sunshine —Mr F W Frohawk exhibited varieties of *Satyrus hyperanthus*, bred from ova laid by a female taken in the New Forest in July last —Mr F D Godman, F R S, exhibited a specimen of *Amphonyx medon*, Cr, received from Jalapa, Mexico, having a pouch-like excrescence at the apex of its body —Mr C J Gahan communicated a paper entitled "Additions to the Longicornia of Mexico and Central America, with notes on some previously recorded species"—Mr W L Distant communicated a paper entitled "Contributions to a knowledge of the Homopterous family Fulgoridæ"—Mr Oswald Latter read a paper (which was illustrated by the Society's new oxy-hydrogen lantern) entitled "The Secretion of Potassium-hydroxide by *Dicranura vinula*, and the emergence of the imago from the cocoon" The author stated that the imago produced, probably from the mouth, a solution of caustic potash for the purpose of softening the cocoon The solution was obtained for analysis by causing the moths to perforate artificial cocoons made of filter-paper Prof Meldola, F R S, said that the larva of *D vinula* secretes formic acid, and Mr Latter had now shown that the imago secretes potassium hydroxide, a strong alkali He stated that the fact that any animal secreted a strong caustic alkali was a new one Mr Merrifield, Mr Hanbury, Mr Gahan, Mr Poulton, and Prof Meldola continued the discussion —Mr H J Elwes and Mr J Edwards read a paper (also illustrated by the oxy-hydrogen lantern) entitled "A revision of the genus *Ypthima*, principally founded on the form of the genitalia in the male sex" Mr McLachlan, F R S, said he attached great importance to the genitalia as structural characters in determining species, and he believed that he could name almost any species of European Trichoptera simply from an examination of the detached abdomens of the males Mr O Salvin, F R S, said he had examined the genitalia of a large number of Hesperidæ, with the view of considering their value in distinguishing species Mr Bethune-Baker, Colonel Swinhoe, Mr. Lewis, Dr Sharp, F R S, Mr Hampson, and Mr Champion continued the discussion —Mr S H Scudder communicated a paper entitled "New light on the formation of the abdominal pouch in *Parnassius*" Mr Elwes said he had based his classification of the species of this genus largely on the structure of this abdominal pouch in the female Mr Jenner-Weir remarked that a similar abdominal pouch was to be found in the genus *Acræa*, and Mr Hampson referred to a male and female of *Parnassius* in Mr Leech's collection, in which the pouch had come away from the female and was adhering to the male organs.

PARIS.

Academy of Sciences, October 31.—On the geometry of position, by M. H. Poincaré —Observations on M Berthelot's communication regarding the fixation of nitrogen, by M Th.

Schlœsing Reply, by M Berthelot —On the laws of compressibility of liquids, by M E H Amagat Deformations of the piezometers were investigated and allowed for in these experiments, and the pressures carried as far as 3000 atmospheres. The liquids operated upon were ether, alcohol, carbon bisulphide, acetone, the ethyl halides, and chloride of phosphorus In every case the coefficient of compressibility was found to decrease regularly as the pressure increased At 3000 atmospheres that of water was reduced by nearly one half its ordinary value, that of ether by two-thirds This diminution again is greater the higher the temperature The ratio of the difference of the coefficient to the corresponding difference of temperature, $\frac{\Delta\mu}{\Delta t}$, increases rapidly with the temperature, and decreases rapidly as the pressure increases The value of $\frac{1}{\mu}\frac{\Delta\mu}{\Delta t}$ also diminishes rapidly as the pressure increases, but whilst for alcohol it grows decidedly with the temperature, for ether it seems sensibly independent of it It is probable that the ratio passes through a maximum at a certain temperature —Observation of the comet Barnard (October 12), made at the Algiers observatory with the *equatorial coudé*, by M F Sy —Elliptic elements of the comet Barnard, by M Schulhof Discussing the probabilities of the new comet being identical with, or a part of, the comet Wolf, which was subjected to considerable perturbations by Jupiter in 1875 —On the equations of dynamics, by M R Liouville —On the solution of the ballistic problem, by M E Vallier —Displacements of a magnet on mercury under the action of an electric current, by M C Decharme If a light magnetic needle be floated on a bath of perfectly pure mercury, and conductors carrying a current be dipped into the mercury at different places, the needle will, before assuming the position of equilibrium according to Ampère's law, go through a series of excursions, rendered necessary by the difficulty of its motion, perpendicular to its length. If the current crosses the mercury in a direction perpendicular to the length of the needle for instance, with the negative pole of the current on the left of the south-seeking pole, the needle will move away parallel to itself, will turn round, and return to take up the normal position —On the temperature of maximum density of mixtures of alcohol and water, by M L de Coppet The lowering of the freezing-point in solutions of alcohol is sensibly proportional to the quantity of alcohol, in confirmation of Blagden's law But the lowering of the temperature of maximum density is not proportional to the percentage of alcohol For weak solutions there is no lowering, but rather an elevation of the temperature of the maximum —On the dissociation of barium dioxide, by M H. Le Chatelier.—On a limited reaction, by M Albert Colson —On the fixation of free nitrogen by plants, by MM Th Schlœsing, jun , and Em Laurent —Purification of drain waters by ferric sulphate, by MM A and P Buisine —Experiments on bread and biscuit, by M. Balland —Ptomaïnes extracted from urines in erysipelas and puerperal fever, by M A. B Griffiths —Hermerythrine, a respiratory pigment contained in the blood of certain worms, by M A. B Griffiths.—Morphology of the skeleton of the star fish, by M Edm Perrier —The secreting apparatus of the *Copaifera*, by M Léon Guignard —New observations on sexuality and parasitic castration, by M. Ant Magnin —A possible cause of the doubling of the canals of Mars; experimental imitation of the phenomenon, by M Stanislas Meunier —Devonian and permio carboniferous of the Aspe valley, by M J Seunes —A short account of the voyage of the *La Manche* to Iceland, Jan Mayen, and Spitzbergen during the summer of 1892, by M Bienaimé The maps of Jan Mayen were found to be very accurate those of Spitzbergen much less so The barometric change in Iceland, Jan Mayen, and the Faroes agreed strikingly with those of Great Britain and Scandinavia, while those of Spitzbergen were of a particular order Pendulum observations gave $g=9\ 82345$ for Jan Mayen, and 9 82866 for Spitzbergen,—Eruption of Etna of 1892, by M. A. Ricco.—The analysis of complex odours, by M Jacques Passy Proceeding from very small doses, say of amyl alcohol, two different perfumes will be perceived to increase and then diminish in succession, finally giving way to an odour which soon becomes disagreeable as it increases in strength. The transition from perfume to unpleasant odour is very general in volatile substances —Immunity against cholera conferred by milk, by M. N. Ketscher —A new apparatus for hypodermic injections, by M. G Bay

THE GEOLOGY OF SCOTLAND

Geological Map of Scotland By Sir Archibald Geikie, D.Sc, LL D, F R S, Director-General of the Geological Survey of Great Britain and Ireland With descriptive text (Edinburgh J Bartholomew and Co, 1892)

THERE have been many attempts to frame a popular definition of man To call him a "story-loving animal" would not be the worst of them It may indeed turn out when we understand monkey-talk a little better than now (and the hope that we may is, we are assured, not unreasonable), then it may be that this will prove to be not an exclusive definition But this by the way, the description will hold for the present Hence the delight with which we listen to all that the various branches of history, the history of the growth of knowledge included, have to tell us It is the stories which first attract us, and they retain their charm long after we have learned that the study of history has other ends to fulfil besides the satisfaction of that craving for story-hearing which lies deep in our being, and the gratification of a natural curiosity to learn about things which we have not seen But the conviction that history should be to us something more than a string of ancedotes soon forces itself upon us

In tracing the growth of any branch of knowledge, in noting the steps by which, one by one, each advance has been made good, our interest lies first of all in the acquaintance, almost of a personal character we may say, which we make with the pioneers of a movement of which we see not perhaps the full development but the ripening fruit. We watch with absorbed attention their approach to the unexplored land, we follow them along the tracks by which they first traversed it, we stand by while they note and record all that is novel and characteristic in its features, we mark the birth and growth of the conceptions which their exploring work gives rise to, we live over again their fascinating life of discovery and deduction But beside and beyond all this, their story, like the stories of all history, carries with it a lesson, and their caution or rashness, as the case may be, in generalizing and drawing conclusions, serves as example or warning to us We look up to candour and a readiness to court criticism and give up explanations which are shown to be untenable, anything like partizanship and a weakly parental predilection for the children of one's own brain we look down upon with sorrowing pity.

The history of the steps by which a knowledge of the geology of a country has been arrived at is written in the successive versions of its geological maps The appearance of a map which embodies the results of the latest researches into the geology of Scotland tempts us to look back upon the earlier efforts to unravel the complications of its geological structure And this all the more because we are dealing with a country in which Geology, as we know it, may be said to have come to the birth; and because it is to Scotchmen that we owe the first showing forth of these principles, whether of observation, deduction, or inductive confirmation, which have been the guide of geologists ever since To Hutton, the precursor of Lyell, to Hall, the scientific ancestor of Daubrée, and to the line of illustrious followers who have carried on with such brilliant success the work which they started

Among the earliest attempts to deal with the geological mapping of Scotland are the maps of Macculloch's "Western Islands," which bear the date of 1819 It is hard for us to realize how much of Scotland was at that time without adequate topographical delineation Our present Ordnance Maps are far from being a credit to the Department which issues them, and the language which attends an attempt to use them on the mountainous moorlands, though not a whit stronger than is justifiable under the circumstances, had better be left to melt into thin air around the spots where it was uttered But our geological life is one of luxury compared with Macculloch's, whose atlas is one string of apologies for the inadequate maps on which he had to record his observations. The map of the Isle of Man "is obviously very inaccurate, but there was only a choice between it and two others equally unworthy of confidence" The map of Staffa "was drawn under every unfavourable circumstance, and cannot fail to be inaccurate, having been merely paced with the assistance of a pocket compass in a severe gale of wind and rain"

Macculloch seems to have projected, but never completed, a geological map of the whole of Scotland The materials collected by him were however utilized by the Highland Society in the construction of a general map in 1832

Passing by the maps of Boué, and a sketch of Murchison's and Sedgwick's, laid before the Geological Society in 1828, we come to the publication of Nicol's "Guide to the Geology of Scotland" in 1844

In a country where the rocks are so largely unfossiliferous, it is natural, even necessary, that the earliest geological maps should be more of a lithological than a stratigraphical character, and this is the case with the maps so far noticed In the map which accompanies Nicol's guide, and which he says is based on Macculloch's, some of the main varieties of the crystalline schists are distinguished, but the order in which they occur is not indicated One colour comprises all the red sandstones, the Torridon, the Old Red, and even the red rocks of Dumfriesshire, under the head of "Porphyry and Trap" are lumped together all the volcanic rocks, including those of the western islands and of the central valley, only two of the groups which we now call formations are separated, the "Carboniferous" and the "Lias and Oolite" But the great leading features in the physical geography of Scotland are sharply marked out, the three regions into which it naturally falls are lucidly delineated, and the work is crowded with local details that betoken acquaintance with the work of others and patient investigation of his own.

At the meeting of the British Association at Glasgow in 1855 Murchison gave an account of the result of the joint work of Nicol and himself in the north western Highlands. The existence of three great sub-divisions had been clearly established; what we now know as the Hebridean or Lewisian Gneiss at the base, the Torridon sandstone resting unconformably on it; while above that, and separated from it by another unconformity, came the

limestones and quartzites of Durness and Loch Erriboll, in which Peach had recently discovered fossils The last group appeared to be conformably overlaid by a great mass of crystalline schists, which came to be known afterwards as the "Upper or Eastern Gneiss" Though the fossil evidence was then incomplete, Murchison saw nothing in it to forbid the belief that the Durness beds were of Lower Silurian age, and his conjecture was confirmed by the discovery of better specimens This conclusion was announced in a paper read before the Geological Society in 1858, in which it was also stated that the author looked upon the Upper Gneiss as metamorphosed Silurian

In the meantime Nicol had read a paper before the Geological Society (1856), in which he describes the joint explorations of himself and Murchison, and some subsequent work of his own He recognizes the same main sub-divisions as Murchison, but still leans to the old notion that the Torridon sandstone belongs to the Old Red, this involves the assigning a later date to the Durness Beds, and these he thinks may be Carboniferous But he is content to hold this merely as a provisional hypothesis till further fossil evidence is forthcoming With respect to the Upper Gneiss he is very cautious, suggesting that it may be a newer metamorphic group, or may be merely a portion of the lower, that is Hebridean, gneiss *forced up by some great convulsion* This latter solution was evidently present very vividly to his mind, for it is repeated, as a possible explanation, no less than three times

Here a very important difference of opinion between Murchison and Nicol makes its appearance

It was probably about this time, but the map bears no date, that Nicol issued a new geological map of Scotland. In this all gneiss is denoted by one colour, but the explanation states that the author does not consider all the Scotch gneiss to be of the same age, that the tract of this rock, with associated quartzite and limestone, stretching from Aberdeenshire through Perthshire to the Breadalbane Highlands of Argyllshire, may be a newer formation; while he is disposed to look upon the great mass of gneiss, extending from the north coast of Sutherland southwards through Ross-shire and Inverness-shire, rather as belonging to an older period The Torridon sandstone is distinguished by a separate colour, though the author is still inclined to class it with the Old Red

Nicol expounded his views to the British Association at Aberdeen in 1859, and again in a paper read before the Geological Society in 1860 He adduces many reasons for doubting the existence of an "upward conformable succession" from the Durness Beds to the Upper Gneiss, and explains the sections on the supposition that this rock is the Hebridean Gneiss brought up by faults Though the expressions, "forced up by convulsion" and "pushed up over," which he uses in his paper of 1856, seem to show that the notion of what we call "Thrust Planes" was present to his mind, the sections of this paper hardly bear out that inference. He neatly twits Murchison with failing to see that the principles which he had applied with such success to an explanation of the structure of the Alps were equally applicable to the North-west Highlands. In 1861 Murchison stoutly maintained his view regarding the Upper Gneiss; with an advocate's skill he hits Nicol hard on his weak point, justly urging "that local interferences of eruptive rock nowise set aside broad data" In the same year was issued the "First Sketch of a new geological map of Scotland by Sir R I Murchison and A (now Sir A.) Geikie," in which Murchison's views vere adopted

Here then was a promise of a fair stand-up fight between two champions, each well able to hold his own. But the promise was not fulfilled The combat would have been far from equal On the one side there were the pull which wealth and social position bring with them, the advantage which accrues from living in London and having thus the ear of a great centre of scientific life, and that pushing ambition, that eagerness to secure precedence in discovery, which so often go along with an active and energetic disposition On the other side there were comparative social insignificance, residence in a hyperborean region far more difficult of access than now, a happy indifference to fame based on a confidence that the settlement might be safely left to time, and that the world would go on pretty much as heretofore, whichever of the two turned out to be nearer the truth more than all a reluctance to embitter the closing years of life with anything that looked like an altercation with an old and esteemed friend and fellow-worker So, because it takes two to make a quarrel, the fight never came off Naturally, under these circumstances, (and can we blame it?) the world took the man who vigorously pushed his views, at his word, he had plenty to say in their favour and said it well, no one gainsaid him, his contention was accepted There will be those who, without presuming to blame, do not covet success on such terms, and whose sympathies go out towards the peace-loving old man who was content to bide his time and possess his soul in silence

And so the "Upper Gneiss" and "the upward conformable succession" held their own, and in the geological map of Scotland, issued in 1876 by the present Director-General of the Geological Survey, the crystalline schists of the Central Highlands are designated "Metamorphosed Lower Silurian" It would be tedious to enumerate all the points in which this map is an improvement on the "First Sketch" of 1861, but the student will find it an instructive exercise to compare the two maps, and ascertain by reference to memoirs on special districts how each correction and addition was arrived at.

The Highland problem remained in abeyance for nigh a quarter of a century, though during that interval the minds of many geologists were constantly recurring to it and evidence was being accumulated to help towards its solution But it came to the front again, and like a giant refreshed with sleep, when Prof Lapworth in his "Secret of the Highlands" (1883), and other workers in the same ground, began to throw doubt on the explanation which had so long held the field. When the Geological Survey were able to take up the question and work out the ground with precision and detail that no observer could attain to single handed, the anticipations of their immediate predecessors were substantially confirmed, and of the earlier observers it came out that Nicol was nearer the truth than his illustrious antagonist.

It calls for no small exercise of judgment, in an endeavour to depict the geology of so complex a district on

a map of small scale, to decide what details must be retained because they are essential to a grasp of its broad general structure, and what may be safely eliminated without impairing the comprehensive view. In the map now before us this end has been compassed with consummate skill. It bristles with detail, but there is nowhere crowding; the colours are well contrasted, and so transparent that they do not hide the topography, which is full and clearly printed.

The richness in detail of the strip of country between Cape Wrath and Loch Torridon marks one scene of the recent work of the Geological Survey. Then follows a broad band of "gneissose and schistose rocks not yet differentiated." A portion of this ground is occupied by the crushed and mangled-out complex of the "Moine schists," but a large part is yet imperfectly explored. To the south-east of the Great Glen we enter again on ground which has been largely worked out by the Geological Survey. We have here a group of various sedimentary deposits in a more or less altered condition, containing sheets of basic igneous rocks. The geological age of this series is not known, and they are provisionally classed as Dalradian.

The presentation of the results of the work of the Geological Survey in the north-west and central Highlands are the two most conspicuous novelties in the map; but during its use other corrections and additions, too small to catch the eye on a general view, become noticeable. In the explanatory notes we have a concise summary of the geology of Scotland, and feel that our thanks are due to the author for having put so much into so small a space without in any way sacrificing descriptive clearness. When the time comes for a new version of the map, may the same hand be with us to draw it up.

A. H. GREEN.

MEDICAL MICROSCOPY.

Medical Microscopy. A Guide to the Use of the Microscope in Medical Practice. By Frank J. Wethered, M.D. (Lond.), &c. With Illustrations. Pp. 412. (London: H. K. Lewis, 1892.)

THIS volume, one of Lewis's practical series, bears an ambitious title, and must necessarily traverse a wide and intricate field of medical work. Its appearance is justified by the distinct need existing at the present time for a manual dealing with the various microscopical methods so essential to diagnostic accuracy and rational treatment.

The subject-matter is arranged in twenty-four chapters, and as an indication of the scope of the book, we instance some of the headings. The earlier ones treat of the microscope and its accessories, the methods of hardening, decalcifying, embedding, section cutting, staining, and injection of tissues. Then follow others on the examination of tissues, urinary deposits, blood, expectoration, and the detection of micro-organisms, and cutaneous parasites; while the latter chapters deal with the examination of food, water, and with bacteriological methods. In fact, the book is almost an epitome of the course pursued by a student earnestly working with the microscope from the commencement to the end of his curriculum. The tendency has been, by the specialized character of the primary examinations in late years, to sever in some degree the knowledge obtained in the earlier part of a student's career from the practical application of the same at the bedside. So much is this the case, that it has been deemed advisable in some quarters to introduce new courses of lectures, their aim being to indicate with precision to students those facts in anatomy and physiology which have a distinct clinical value. One of the chief merits of Dr. Wethered's book is that he has therein demonstrated the important relationship between histology and morbid anatomy, and has shown that any attempt at acquiring a knowledge of the latter is dependent upon a practical and searching training in the former.

Moreover, the book is worthy of more detailed criticism. Necessarily in a first edition there are some points omitted. In speaking of the microscope the author offers a cursory remark on the fine adjustment, no mention is made of the best pattern, and there are many of an inferior and useless description foisted on students; nor are there any directions for the precise use of this portion of the microscope. In the chapter on "Hardening and Decalcifying Tissues," on p. 35, are found some well-meant platitudes on the necessity of immediately labelling specimens; but at the same time the use of lactic acid as a decalcifying agent is omitted. We have succeeded in completely softening small pieces of bone in 4-7 days, and teeth may be cut with the freezing microtome in from two to three weeks.

With certain statements of the author we venture to disagree. In speaking of the celloidin method he advises that the specimen be placed in equal parts of ether and alcohol previously to being placed in celloidin. A mixture of four parts of ether and one part of absolute alcohol ensures more rapid and complete penetration of the embedding material. Also in using paraffin for this purpose we have found by extensive practice that sections containing a large amount of fibrous tissue are useless after being in the paraffin bath for three to five hours, even at a temperature of 48° C.; twenty to thirty minutes is ample, provided that the material is properly dehydrated. The chapter on staining is succinct and comprehensive, and we note the usual and indeed only rational classification of stains, as nuclear, general, and selective. Hæmatoxylin still holds the first place, and Delafield's, or as it is miscalled, Grenacher's, is undoubtedly the best formula. It is here stated that if the sections be overstained, and washing in acid-alcohol be necessary, the colour is not permanent. Our experience is that if after the acid they be washed thoroughly well with "tap water," a very clear nuclear stain results which remains unchanged for years. Gram's method of staining for micro-organisms, with Weigert's modification, is clearly detailed. But here we fail to observe any mention of the brilliant results obtained by the Ehrlich-Biondi method. The employment of rubin for actinomycosis may with confidence be recommended, and the same remark applies to the use of saffranin in bringing out clearly the nuclear figures in karyokinesis. The chapter on mounting is somewhat tedious and the use of origanum oil in clearing celloidin-specimens is not advocated, although it has found general acceptance in Continental laboratories.

Weigert's method of preparing and staining nerve-tissue is given, but with one important detail left out, viz., that on removing the specimen from Muller's fluid or chromic acid solution it should have a brown, and not a green colour. The preparation of individual tissues and organs is well dealt with in chapter xii., but in the succeeding one on the examination of tumours there are such evident signs of hasty composition as to render it of small intrinsic value. On the other hand, the important subjects of urinary and excrementitious matters receive ample treatment; and we have a clear *résumé* up to this date of all that is taught on these subjects. As an example we note with pleasure the account of Dr. Delepine's work on "sable intestinal." The bacillus of Asiatic cholera and the methods of its detection are described on p. 228, and the diagnostic points between it and that of cholera nostras are found on the next page. A large amount of space is necessarily devoted to the examination of sputa. Dr. Wethered's experience at the City of London Hospital for Diseases of the Chest enables him to speak with the voice of authority on the signification of the presence or absence of the tubercle bacillus. Physiologists will find their side of the question well considered in the observations on blood; on Dr. A. Garrod's authority we are told that the blood of the Londoner has not yet been found to contain its true proportion of hæmoglobin. Eosinophile cells are not omitted; but for more detailed information on this point we commend to the notice of pathologists the article by Dr. A. Kanthack in the *British Medical Journal* of June, 1892.

Medical microscopy as a subject is exceedingly elastic, and we believe Dr. Wethered has stretched it to its widest limits when he finds space for describing the examination of various kinds of cereals, also of water. Even the homely tea-leaf has not escaped his notice. A few instances of clerical errors are to be found, thus Hartnach for Hartnack, on p. 122, Richert for Reichert. At the term "collodionization" we venture to express our distaste. A growing practice exists of introducing ungainly expressions of doubtful expediency into scientific works.

We have read this book with considerable attention, and are convinced that it has a most distinct *raison d'être*, and justifies on the whole, by the merit of its execution, the ambition of its title. It treats of the matter in hand with much ability, and in a manner that evidences considerable experience on the part of the author as a pathologist, physician, and teacher.

A. H. TUBBY.

ODOROGRAPHIA

Odorographia: a Natural History of Raw Materials and Drugs used in the Perfume Industry. By J. Ch. Sawer, F.L.S. (London: Gurney and Jackson, 1892.)

CONSIDERING the importance of the subject of perfumes both from a scientific and a commercial point of view, it is somewhat surprising that a really good and authoritative book dealing on the matters encompassed by "Odorographia" has not before been attempted. The delay in the appearance of such a work is probably due to the fact that but few persons possess the requisite knowledge to treat the subject in a thoroughly satisfactory manner in all its bearings, such as the origin and production of the numerous products, whether animal or vegetable, and the chemical aspect of every substance and its commercial value, which are points that could scarcely be expected to be mastered by one mind. In the "Pharmacographia" of Fluckiger and Hanbury, two master minds on the subject of drugs were brought into co-operation, with the result that a most satisfactory and standard work on medicinal plants was produced. That this book was in the mind of the author when he compiled his "Odorographia," and selected its title, is quite apparent, and we are bound to say that on the whole he has done his work remarkably well, though we wish that he had adhered more strictly to the lines of his pattern. Mr. Sawer, however, at the very commencement of his preface, is so modest as to say that "an endeavour has here been made to collect together into one manual the information which has hitherto been only obtainable by reference to an immense number of works and journals, English and foreign, in many cases inaccessible to readers interested in the subject," and that he is thoroughly well acquainted with all that has been written is apparent not only from a glance through the pages, where numerous references occur, but also from the "List of Principal Works referred to." Besides this the author has, as he tells us, obtained information first hand from some of the largest perfume-plant growers and manufacturers of Grasse, Nice, and localities in the Straits Settlements and West Indies. The difficulties attending the compilation of a work of this nature have, no doubt, been very great, because scraps of information are so widely dispersed, and even when found oftentimes very confusing. The botany alone of the subject must have occupied a considerable amount of time in looking up, the plants yielding perfumes being natives of various parts of the globe, and consequently described in the several floras appertaining to those special countries, besides which the chemical and commercial aspects occupy a large portion of the book.

Though we are grateful to Mr. Sawer for giving us a book that was really wanted, we regret, as we said before, that he has not followed more closely the plan of the "Pharmacographia" and arranged his matter under distinct heads, such as History, Botany, Cultivation, Chemistry, Commerce, &c. Practically he has done so to a certain extent, but the paragraphs are not sufficiently distinguished to enable one to turn at once to that upon which information may be specially sought. The arrangement of chapters, in which the most important and marked odours, such as those of musk, rose, violet, the citrine odours, &c., are brought together, is good, but the principal plants in each of these groups might have been treated as we have described, the least important ones being given as they are at the end of the chapters.

Returning to the botany of the book, we cannot but think that the author might well have spared much space by the omission of numerous varietal names and synonyms, many of which are scarcely ever heard of now, and which often only tend to confusion. Under Violet, for instance (p. 104), half a page is given to a list

of the names of nine varieties of the Sweet Violet (*Viola odorata*) Again, at p 309, Vétiver, or Cus Cus, is rightly described as the root of *Andropogon muricatus*, after which follow the names of five synonyms In reference to this Mr Sawer says, referring to the "Asiatic Researches," that "there is a verse in the Sanskrit language composed of nine words, arranged in two lines, purporting to be the nine names under which the plant was known, doubtless they were poetical names, as they are not found in the extensive list of local names recently enumerated by Watt" This would show that Dr Watt, who in his "Dictionary of the Economic Products of India" does not err on the score of brevity in the adoption of synonyms, considered that there was a line to be drawn somewhere We may perhaps also be allowed to draw attention to a paragraph on page 19, where the musk tree of Jamaica and the muskwood of Australia have got confused The paragraph in question runs thus, "The *Eurybia argophylla* or *Guarea Swartzei*, the silver-leaved musk tree of Jamaica, New South Wales, and Tasmania, is a meliaceous tree, attaining a height of twenty-five feet" Eurybia, or more properly *Olearia argophylla* is the muskwood of New South Wales and Tasmania, and belongs to the natural order Compositæ, while *Guarea Swartzii* is a meliaceous tree of Jamaica, where it is known as musk tree Another muskwood, not mentioned by Mr Sawer, is that of *Moschoxylum Swartzii*, a highly fragrant resinous tree, closely allied to *Guarea*, and a native also of Jamaica and Trinidad We refer to these matters in no captious spirit, but simply with the hope that Mr Sawer may see his way to overhaul and modify this part of his useful book in a future edition, so as to make it even more useful and trustworthy We are glad to note that he "is still engaged upon studies in this department, and hopes to publish another volume in due course"

OUR BOOK SHELF

Catalogue of Eastern and Australian Lepidoptera Heterocera in the Collection of the Oxford University Museum By Colonel C Swinhoe Part I Sphinges and Bombyces (Clarendon Press, 1892)

THIS volume is the first part of a Catalogue of the moths from the Oriental and Australian regions in the collection of the late Mr W W Saunders, which was acquired by the Oxford Museum some fifteen years ago, and consists chiefly of specimens collected by Wallace during his famous voyage to the Malay Archipelago, and described by the late Francis Walker in his British Museum Catalogue Since Walker's arrangement of the collection it has remained untouched and mostly neglected by lepidopterists, so that a rearrangement and comparison of the types had become highly necessary, which useful work has been undertaken and very ably carried out by Colonel Swinhoe All the types have been brought to the British Museum, their synonomy carefully worked out and the species placed in their proper families and genera, many of them being figured in the eight coloured plates, and it is to be hoped the other parts will soon follow, and also that a list of the types which should be in the Museum and are missing will be added There is one statement in the preface which requires correction, the only types of Walker's species described in his Catalogue which are in the Oxford Museum are those which are expressly stated to be in "Coll Saunders," all the others are in the British Museum, including those for which a locality is given before the list of British Museum specimens

Charles Darwin His Life Told in an Autobiographical Chapter and in a Selected Series of his published Letters Edited by his son, Francis Darwin (London John Murray, 1892)

PROF DARWIN describes this volume as practically an abbreviation of the well-known "Life and Letters" The task of compression has been accomplished admirably, and there can be little doubt that the work will be cordially appreciated by a large number of readers Of course it has been necessary to omit many details which are of interest to men of science, but everything is included which is really essential to a proper comprehension of Darwin's fine personal character, and a sufficiently full and clear idea is given even of his scientific labours No one will read this fascinating book without feeling anew how much reason England has to rank Darwin among the greatest and noblest of her sons The volume is enriched with a reproduction of an exquisite photograph of Darwin by the late Mrs Cameron

Strange Survivals Some Chapters in the History of Man By S Baring-Gould (London Methuen and Co, 1892)

EVERY one who has given any attention to anthropology is aware that many remarkable customs and beliefs, which are still to be found among the uneducated classes even in highly civilized communities are relics of ancient superstitions. In the present volume Mr Baring-Gould examines various groups of these curious survivals, and traces them back to their origin in the ideas of past ages He knows his subject well, and, being interested in it himself, is able to present it in a way which is likely to make it interesting to others The value of the text is considerably increased by some well-selected illustrations

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Botanical Nomenclature

IN NATURE for October 6 (p 549) there is a note "on the progress of the negotiations concerning the nomenclature of genera, started by a committee of botanists at Berlin to supplement the decisions of the International Botanical Congress held at Paris in 1867" It is stated that "the botanical authorities of the British Museum favour the suggestions, those at Kew are against them"

Now this requires a little correction It may be remarked to begin with that many botanists are exercised at the present time not merely about the nomenclature of genera, but also about that of species Kew has, however, never given its adhesion to the attempts that have been made to bring about an international agreement on these matters. It has always felt that so many considerations must determine the course taken by the systematist in any particular case, that there is no advantage, but positive inconvenience, in being subjected to a hard and fast rule. It is therefore with no disrespect to, or want of sympathy with, the able school of Berlin botanists, who have recently formulated some new proposals with regard to nomenclature, that Kew has officially refrained from expressing any opinion upon those proposals. It has neither expressed approval nor disapproval.

In America Harvard has long occupied the leading place in the botanical world, and the principles adopted there have been substantially in accord with those adopted at Kew Hitherto,

therefore, the leading English-speaking botanists who have occupied themselves with systematic botany have been in substantial agreement that the adoption of a strict law of priority in nomenclature must give way to considerations of convenience

Well known and accepted names are not therefore to be lightly changed as the result of mere bibliographical research As to specific names the often merely mechanical process of describing a new species is held to be of little value compared with the more difficult task of assigning to the plant described its true affinities and correct systematic position The principle which guides Kew practice in this matter is laid down by Sir Joseph Hooker in the preface to "The Flora of British India" (p vii) He remarks —

"The number of species described by authors who cannot determine their affinities increases annually, and I regard the naturalist who puts a described plant into its proper position in regard to its allies as rendering a greater service to science than its describer when he either puts it into a wrong place or throws it into any of those chaotic heaps miscalled genera with which systematic works still abound"

The following paper on the subject deserves the wider circulation which its reprint in NATURE would give it It represents the Harvard tradition and practice, and is the last scientific utterance of Dr Sereno Watson, who so soon followed to the grave his illustrious predecessor, Asa Gray

Kew, November 14. W T THISELTON DYER

ON NOMENCLATURE [1]

[It was the request of the late Dr Sereno Watson that the following communication, dictated by him in his last illness, should appear at an early date in the *Botanical Gazette* —EDS]

FOR some time I have had a desire to give expression to my views upon botanical nomenclature Under the circumstances, I must speak briefly and somewhat dogmatically. In my opinion botany is the science of plants and not the science of names Nomenclature is only one of those tools which is necessary to botany, and this being the case, points of nomenclature should be subordinated to science.

A principle of botanical convenience has been established by those who prefer one name to another on account of expediency or convenience This principle should have a great deal of influence It has been so recognized by the greatest botanists, and from their authority receives great weight I prefer the word *expediency* as a better term than convenience to designate the principle, that the demands of science over-ride any merely technical claims of priority, &c

Priority of specific names appears to be based entirely upon one section of the code of 1867 That simply says that when a species is transferred from one genus to another, the specific name is maintained. This principle is usually understood and applied in the way that the oldest specific name has a right in all cases to be retained It cannot fairly be so interpreted and applied, since it governs only to the extent that this should be the law, but it is not to be made an *ex post facto* law Thus when a transfer has been made, that ends the matter so far as the choice of a specific name is concerned, and no one is authorized to take up a different name This practice of retaining the oldest name *under the genus*, no matter what older specific names there may be, was adopted by Dr Gray in his later years and by the Kew botanists, for the reason that once established and pretty generally recognized, it would avoid the great mass of synonymy, which is being heaped like an incubus upon the science. I must express surprise that Dr Britton had not considered it his duty to publish the last written words of Dr Gray which were addressed to him upon this subject and which expressed his positive opinions upon this point

There is nothing whatever of an ethical character inherent in a name through any priority of publication or position which should render it morally obligatory upon any one to accept one name rather than another, otherwise it would be applicable or true as well in the case of ordinal names, morphological names, teratological, and every other form of name, to which now no one feels himself bound to apply the law of priority. The application of this law as at present practised by many botanists, which would make it the one great law of botanical nomenclature, before which every other must yield regardless even of common sense, is a mere form of fetichism exemplified in science Many instances of the application of this law are not science but are rather superstition SERENO WATSON

The Reflector with the Projection Microscope

THE lantern is now used for so many purposes—scientific, photographic, and recreative—that any improvement in its construction will be acceptable When we look into this instrument whilst at work we must be disappointed at the large quantity of light lost by reflection and by dispersion—light which ought to go to the illumination of the screen In the ordinary form of the lantern three lenses of dense glass are employed as condensers Each of these six surfaces reflects and scatters the light, and the glass itself is absorbent of its rays

The dioptric construction of the projection lantern has been well worked out by Messrs Wright, Newton, Salomons, and others, but the catoptric principle, which would eliminate almost entirely these disadvantages, has been scarcely at all studied

Although my experiments have been made solely with the limelight in various forms, the following remarks may equally apply to light given by the electric arc :—

If a reflector be used instead of the ordinary condensers it is obvious that the position of the lime cylinder must be reversed This will present no difficulty, for the tube holding the jet can be bent into a helical form The dark image of the lime-cylinder also will have no more practical disadvantage than is experienced by a like image formed by the small plane speculum of the Newtonian telescope

As to the mirror itself, although a parabolic form is the most correct, a spherical surface will be sufficient for mere illuminating purposes, and thus expense may be spared in the grinding of the more difficult curve A speculum of from 5 to 7 inches diameter, having a radial curvation of from 2½ to 3 inches, will grasp a large quantity of light, much more than that obtainable from the 5-inch condenser usually employed.

Silver deposited by one of the various reducing processes on the surface of a clear glass lens will have many advantages over a metal mirror. The front surface will give perhaps the finest definition, but by silvering the back part of a spherical glass film, or that of a ground lens, the brilliant surface will remain untarnished for an indefinite time, and the whitish bloom formed by slow volatilization of the incandescent lime is easily removed This silver film adheres with remarkable tenacity, and it will bear a great deal of heat without blistering or becoming detached

I have had considerable success in constructing such mirrors from the large ornamental glass spheres blown in Germany, and silvered within by Liebig's process, viz with milk sugar and ammonio nitrate of silver A glass sphere of 10 or 11 inches in diameter may be easily cut into eight or nine mirrors by a red-hot iron, and this without disturbing the silvering, which will require only gentle friction with a pad of cotton impregnated with a trifle of rouge to brighten it Thus, at the cost of a few shillings, eight or more mirrors can be made, and also provision be made against possible accidents of cracking by heat

The light radiant is so placed that the secondary focus is intercepted by a plano-concave lens of dense glass, as has been happily proposed by Mr L Wright The convergent rays from the speculum are thus made into a parallel beam, which must be deprived of its heat by an alum-trough, for the light and heat at the substage condenser is very great

Convergence, I find, is usefully promoted by a plano convex lens of about eight inches focus, placed two or three inches before the above-noted plano concave lens. In all other respects the arrangements are like those of the usual modern projection microscope

I have pretty constantly used the ether-oxygen saturator, and I consider it to be perfectly safe, if ordinary precautions be taken. The oxygen, compressed in cylinders, is much recommended, as there can be no mixture of vapour, except at the right place. The U-shaped horizontal saturator, plugged with flannel, must be well charged with ether, or with the best gasolene, and care should be taken, before beginning or ending an exhibition, to shut off the oxygen tap before closing the ether

tap. This will prevent the harmless "snap" from the mixture in the small chamber at the joining of the gas tubes If a disc more than eight feet be required for the microscope, it will be well to use hydrogen gas instead of ether, since the calibre of the jet cannot in the ether light very well exceed $\frac{1}{15}$ of an inch

As an extra security, I pack the mixing chamber with asbestos fibre, moistened with glycerine, but, as before urged, the oxygen must leave the saturator, saturated

To insure the coincidence of the foci of the reflector with the optical axis of the microscope, it will be well to place three adjusting screws in a triangle behind the mirror, and this last may have both a small vertical and horizontal movement

I claim for this catoptric arrangement a larger grasp of light than can be got from ordinary lenses, and this may be effected also at a small outlay For the amateur constructor the plan will afford many advantages G B BUCKTON

Note on the Colours of the Alkali Metals

WHEN these metals are heated in a vacuous tube in such a way as to cause an extremely thin sublimate of the metal to condense upon the glass, the film so obtained will be found to possess a beautiful and strongly marked colour That this colour is not in any way due to the combination of the metal with any lingering minute traces of oxygen, is evident from the fact that vacuous tubes which have contained the clean and bright metal for years, and in which the metal has been frequently melted and rolled about, and even vapourized in places, and in which, therefore, it is impossible to conceive of any oxygen remaining, will continue to show the phenomenon whenever a portion of the contained metal is heated The experiment may readily be made by introducing a freshly cut fragment of the metal into a glass tube sealed at one end and drawn down to a narrow and thickened constriction near the middle The tube is then drawn out at the open end and connected to a Sprengel pump As soon as a good vacuum is obtained the tube is warmed throughout its entire length, the pump being still in operation, and the metal heated sufficiently high to cause it to melt and run out of the crust of oxide When the exhaustion is again as complete as possible the tube is sealed off The metal is once more melted, the whole tube being at the same time gently heated, and the molten mass allowed to filter through the constriction into the other portion of the tube The vacuous condition of the tube allows of the metal freely running through an extremely fine aperture, and in this way it becomes perfectly separated from all dross. The tube is then sealed off at the constriction On gently heating a minute fragment of the bright metal so obtained, by means of a small pointed gas flame, the coloured film of sublimed metal will at once be seen Viewed by transmitted light, the colour of the film of sodium thus obtained is greenish-blue, inclining to green. Potassium gives a sublimate which is of a magnificent rich purple colour, while rubidium, on the other hand, forms a film which is a pure indigo blue

In the cases of sodium and potassium, the colour of the metallic sublimates is different from the colour of the vapour as seen when the metals are boiled in an atmosphere of hydrogen Potassium, it will be remembered, yields under these circumstances a vapour possessing an emerald-green colour, while that of sodium, which appears colourless when seen in small layers, shows a violet or purple colour when viewed through a sufficient thickness

When the liquid alloy of sodium and potassium is treated in the same way, the sublimate obtained is found to be greenish in colour nearest to the source of heat, quickly shading off to blue and purple as it is more remote from that point, indicating apparently that the two metals sublime separately.

As a means of observing these colour phenomena, this alloy is more advantageously employed than the solid metals themselves, for, by rolling the liquid about, the sublimate may be wiped away and the experiment repeated indefinitely in the same tube.

As to whether the colours of these sublimed films are properties intrinsic to the particular metals, or are merely a function of the physical condition of the substances, it is perhaps rash to dogmatise. A number of other elements have been treated in a similar manner, but without similar results; thus lithium, cadmium, mercury, arsenic, tellurium, and selenium, when heated in vacuous tubes are readily sublimed, but in no case does the film appear coloured. On the other hand, however, it is well known that some of the very malleable metals when beaten out into thin films are capable of transmitting light varying in colour from green to violet. G S. NEWTH

Women and Musical Instruments.

IN answer to Prof O T Mason's letter which appeared in a recent number of NATURE (vol xlvi p 561), I may draw attention to the following facts which bear upon a part of the subject which he broaches, namely, the part played by savage women in the use of musical instruments In the South Pacific the "nose-flute" is very generally, though by no means exclusively, played upon by women In the account of the voyage of Capts Cook and King there is in one of the plates a figure of a woman of the Tonga Islands seated under a hut playing upon a "nose-flute" A similar figure of a woman playing upon a "nose flute" may be seen in plate 28 of Labillardière's "Voyage de la *Pérouse*," in the representation of a Tongan double canoe. Melville ("Four Months' Residence in the Marquisas Islands," p 251) mentions playing upon the "nose-flute" as being "a favourite recreation with the females" In Wilkes' "U S Exploring Expedition," iii p 190, there is a description of this instrument as used in the Fiji Islands, and it is stated that "no other instrument but the flute ['nose flute'] is played by the women as an accompaniment to the voice"

Turning now to another genus of primitive instruments, viz, the "musical bow," we find a peculiar local form, the "Pangolo,' occurring at Blanche Bay, New Britain There are specimens of this at Berlin and Vienna This instrument is stated by Dr O Finsch (*Ann des K K Naturhist Hofmuseums*, suppl vol iii pl I, p III) to be only played upon by women of Blanche Bay Guppy too ("Solomon Islands," p 142), says that the women of Treasury Island produce a soft kind of music by playing, somewhat after the fashion of a jew's-harp, on a lightly-made fine stringed bow about 15 inches long

It cannot, I believe, be said that any of these instruments have been *invented* by women, and it is undoubted that women in savagery but seldom figure as performers upon musical instruments It would certainly be interesting to collect all the instances recorded I hope that the above few notes regarding instruments in the South Pacific may be of use to Prof Mason, and I can only regret that lack of the necessary time prevents my going further into the matter

University Museum, Oxford, November 7 HENRY BALFOUR

AN ANCIENT GLACIAL EPOCH IN AUSTRALIA

A VERY interesting "special report" has just been issued by the Department of Mines of Victoria, giving an account of the remarkable evidences of glaciation observed at a locality about twenty miles south-east of Sandhurst, and about the same distance north of the great Dividing Range [1] The report is illustrated by a map and sections on a large scale, and by eight excellent photographic prints, showing the character of the deposit on the surface and in railway cuttings, the striated bed rock, and the striated and grooved blocks and boulders, so that full materials are given for the conclusion that we have here an undoubted glacial deposit A brief summary of this report will therefore be interesting to all students of the phenomena and problems of terrestrial glaciation

The district now specially described is about fifteen miles in one direction by five in another, and over this area of about thirty-six square miles the conglomerate is continuous, overlying the Silurian rocks of the district It has generally a rounded or undulating surface, but shows cliffs about 100 feet high in some of the gullies, and its maximum thickness is estimated at 300 or 400 feet, while its highest point is about 700 feet above sea-level. As well seen in the cliffs and several railway cuttings, the conglomerate consists of a matrix of sand and clayey matter containing huge boulders, great angular and sub-angular masses of rock, pebbles, and rock-fragments of endless variety of size, form, and material Many of these masses are planed, scored, striated, or polished.

[1] "Notes on the Glacial Conglomerate Wild Duck Creek" By E. J Dunn, F G S. (R. S Brain, Government Printer, Melbourne, 1892.)

Planing is very common, and is either flat or with a hollow or a convex surface. Some of the intensely hard hornfels blocks have been ground on one or more sides, several planes being sometimes ground on the same stone, while some very hard rocks are deeply grooved. In other cases the striations and scratches are so fine as only to be seen with a lens; while one surface block of very hard material has been ground down and polished, so that it glitters in the sun. In fact, every form of surface grinding produced by recent glaciation appears to be here present.

The surface of the ground is everywhere strewn with pebbles and boulders, the result of the washing away of the finer materials of the conglomerate; but, besides these, there is a tract of about two and a half miles by one mile near the centre of the conglomerate-area, on the north side of Mount Ida Creek, which is rather thickly strewn with large blocks, termed by the writer "erratics," though they can hardly be erratics in the sense of having been deposited on the present surface by ice. There are forty five of these blocks, which are either of granite, sandstone, or quartz, and vary in size from 6 feet by 4 feet, to 20 by 12 feet. One of the finest, termed "The Stranger," of coarse-grained granite, is 16½ feet by 10½ feet, and 5 feet thick, the estimated weight being 30 tons. It is planed and scored in a remarkable manner, as are most of the other blocks. It is curious that beyond this limited area only three or four large blocks are found on the surface, while no pebbles or boulders derived from the conglomerate are found more than a hundred yards beyond the present limits of that formation.

A striking feature of the conglomerate is the great variety of rocks present in it, seeming as if "the débris of a continent" had been here gathered together. There are an almost infinite variety of granites, syenites, gneisses, schists, quartzites, sandstones (hard and soft, coarse and fine), slates, shales, conglomerates, amygdaloids, porphyries, vein quartz, red, yellow, and grey jaspers, and many others. Some of these can be identified with existing rocks, but others are not known in Victoria. In some cases there is what appears to be river shingle, in others the delicate scratches preserved even on soft shale show that the material has not been exposed to any denuding action. There are also sandstone beds of considerable extent and thickness intercalated with the conglomerate, indicating that there were alternating periods of river or current action while the conglomerate was being formed.

The whole of the phenomena here briefly sketched point unmistakably to glacial action; in fact, there seems to be hardly any part of Wales or Scotland where such action is more clearly indicated. There are, it is true, no moraines, because the period when the conglomerate was laid down is too remote, both newer and older pliocene rocks overlying it in some places. Indeed, from fossils found in shales overlying what appears to be a similar conglomerate at Bacchus Marsh, south of the Dividing Range, the writer of the report is inclined to consider the whole formation to be of Palæozoic age. In one part of the area the bed rock is exposed, and this is covered with abundant striations crossing the stratification lines, indicating either powerful glacier or iceberg action.

A list of localities where similar conglomerates have been found is given, showing that they occur to the northward for about 250 miles along the foot of the hills bordering the Murray valley, disappearing under the Tertiary deposits of the lowlands; they have also been met with forming the floor of the auriferous deposits in mines at Creswick and Carisbrook, on the northern slopes of the Dividing Range, and also, as already stated, at Bacchus Marsh, and a few other localities on the south side of the range. We are not told, however, whether similar indications of glacial action occur in these localities. If these deposits are really all glacial and contemporaneous, they indicate an extent of glaciated country that would imply either a very lofty mountain range or the occurrence of a real glacial epoch in the southern hemisphere.

The direct evidence of the superposition of Tertiary rocks of Pliocene age shows that the glacial conglomerate itself is of great antiquity, but no special attention appears to have been given to the question of the age of the so called "erratics." The fact that they are found in so limited an area seems to show that they are not derived from the conglomerate itself by the process of sub-aerial denudation, and the same thing is indicated by the apparent fact that they all rest upon the present land surface. The photographs seem to indicate this, and nothing is said about their relations to the subjacent conglomerate, or whether any considerable proportion of them still form part of it, merely protruding above the surface, as would certainly be the case if they owe their present position to the mere washing away of the finer parts of the deposit. But, if so, why should they be called "erratics," as distinguished from the blocks and boulders which are still embedded in the formation? If, on the other hand, they are supposed to be true erratics—that is, to have been deposited on the present land-surface by ice agency—they must clearly be much less ancient than the conglomerate itself, or they would hardly retain such fresh-looking striations, grooving, and polishing as some of them exhibit. It is to be hoped that these most interesting deposits will be the subject of very careful study by Australian geologists, since they seem calculated to throw much light on the geological history of the old Australian continent.

ALFRED R. WALLACE.

ON THE WALKING OF ARTHROPODA

IN a letter to NATURE, published January 8, 1891, I described the manner of walking of several insects. Recently I have been able to examine a greater number of Hexapoda, together with several Arachnida and Centipedes, and a few Crustacea. The results of most of these observations were communicated to the Royal Dublin Society a few weeks ago.

I stated in my former letter that most usually the insects examined moved three legs, *e.g.* the 1st and 3rd on one side, and the 2nd on the other, almost, but not quite, simultaneously. In some insects it is the most anterior leg of this tripod which is raised first; in others it is the most posterior. An example of the first case is the cockroach, and of the second the blow-fly. But again exceptions appear to occur in each case. This almost simultaneous raising of the "diagonals" is shown by observations, photographic and otherwise, to be the rule in all the adult Hexapoda which I have examined, except the Thysanura. Of this last group I have observed *Tomocerus longicornus*, and find that, while it often moves by the simultaneous use of the diagonals, it also often raises its opposite legs simultaneously in pairs, especially when the animal is walking on a smooth surface, and using the sucker which is placed on the anterior part of the abdomen.

This use of the opposite legs in pairs was also found very frequently, as well as the diagonal walk, in the larva of one of the Coleoptera, and is always to be observed in caterpillars. Thus it is interesting to find that in one species at least of the Thysanura, which are regarded as having preserved many of the characteristics of primitive insects, the adult walks in the same manner as the larvæ of other insects.

It is to be observed that those insects which have long antennæ move them, and apparently the maxillary palps, in accordance with the diagonal rule; for when the front leg of one side is moved the antenna of that side is twitched.

A midge and some arachnids very frequently use the front pair of walking legs as antennæ. The midge which I observed probably belonged to the Cheironomidæ; it often, when at rest, stood on the two posterior pairs of legs with the anterior pair aloft in the air; when walking it moved them much as a beetle moves its antennæ, gently tapping the ground in front of it with them, their motions being always subject to the diagonal rule; in flight the midges often hold the anterior pair of legs straight out in front, while the last pair are held out in a similar manner behind, and probably have the effect of balancing the insect.

The spiders photographed (*Tegenaria Derhamii* and *Tarantula pulverulenta*) also exhibited the diagonal motion and sometimes the use of the anterior pair of legs as antennæ. When, in order to photograph them, these animals were put on a piece of paper floating in a shallow dish of water, so as to confine them without casting a shadow on the space in which they walked, they used frequently to stand on the three posterior pairs of legs at the edge of the paper, while they moved their anterior pair of legs through the air, or touched the water lightly with them. Several spiders—for instance, *Theridion Sisyphum*—have the anterior pair of legs longer than the others, and very frequently seem to use them as tactile organs. Specialization in this direction is carried very far in the Pedipalpi, in which group the anterior pair of legs are very long, thin, and flagelliform.

The wave of motion in one set of diagonals (*i.e.* the 1st and 3rd of one side, and the 2nd and 4th of the other) in the Tarantula sometimes travelled from before backwards and sometimes in the opposite direction; while in Tegenaria it passed on the whole forwards, but sometimes commenced by the raising of one of the middle legs, or by the raising of the two extreme legs of a set.

When confined on the floating island of paper, the Tarantula sometimes, after a good deal of hesitation, took to the water. When on the surface of the water, its legs, and sometimes the under surface of its abdomen, made conical capillary depressions in the surface, so that the water acted as a diffusing lens to the sunlight, and a dark circular shadow surrounded with a bright line appeared on the bottom of the dish corresponding to the depression at the tip of each leg. This suggested a method of determining the weight supported by each leg, for the diameter of the depressions, and consequently that of the shadows, bears some ratio to the weight on the point which causes the depressions. By fixing the leg of a spider on the end of a straw, hung delicately as a balance-beam, and by measuring the diameters of the shadows caused by the depressions in the surface of the water formed by this leg for various positions of a rider on the straw, I find that these diameters are approximately proportional to the weight on the point causing the depressions. Thus, by dividing the total weight of the spider proportionally to the diameters of the shadows, we get approximately the weight on each leg.

Fig. 1 is from a photograph of the Tarantula standing

FIG. 1.

on water; above the spider in the picture is its shadow on the bottom of the vessel, and at the ends of the three posterior pairs of legs in the shadow appear circular shadows corresponding to the depressions made by the legs; and there is also a shadow thrown by the depression caused by the abdomen. The weight of this spider was 30 mgrs. Thus we find that approximately the weights on the legs are the following:—On the right side, 2nd supports 1·875 mgrs.; 3rd, 7·125 mgrs.; 4th, 3·375. On the left side, 2nd, 4·875 mgrs.; 3rd, 5·250; 4th, 3·000; and the abdomen supports 4·500 mgrs. When walking, the Tarantula usually supported all its weight on a tripod formed by the 2nd and 4th legs on one side, together with the 3rd leg on the other side. The weights on the tips of the legs when one photograph was taken were found to be:—On the 2nd right leg, 9·50 mgrs.; on the 4th right, 10·25; and on the 3rd left, 10·25.

Profile photographs also seem to show that the 1st pair of legs are not generally used to support much weight. Fig. 2 is a diagram of the positions of the 1st pair of legs

a b c d

FIG. 2.

drawn from a number of profile photographs of Tegenaria. The first position, *a*, is that of the leg which has been thrown forward, and is just about to come to the ground; *d* shows the position of the 1st leg when the body has come forward, owing probably to the traction of this leg as well as to the pushing of some of the other legs, and so the leg is bent; *b* and *c* are intermediate positions. The next

a b c d e

FIG. 3.

figure is a somewhat similar diagram of the 4th pair of legs made from profile photographs. At *a* the leg has just been moved forward, and is on the ground, and is in a good position both for bearing the weight of the body and shoving it forward. At *e* it is stretched to its full length, and so is not of any use in driving the spider forwards, while, owing to its almost horizontal position, it is almost useless in supporting the weight of the body. Accordingly the spider has commenced to raise the extremity of the leg prior to lifting the leg completely off the ground.

Last autumn I had the opportunity of observing two scorpions which Mr. R. J. Moss brought from North Africa and exhibited at the Royal Dublin Society. These also appear to proceed according to the diagonal rule; but I do not know what is the order of succession in one set of diagonals, as I have not yet photographed any of these animals.

The hermit crab uses three pairs of legs in walking—the chelæ, and two pairs of thoracic walking legs; these it uses according to the diagonal rule, whether it walks sideways or forwards. Sometimes it simply shoves the chelæ along the ground without lifting them, while it moves the two pairs of legs in a diagonal manner. One of the Asellidae I found often used the opposite legs in pairs simultaneously when walking.

The centipede does not either raise its opposite legs in pairs together, nor does it move its legs according to the diagonal rule. In a number of photographs taken with an exposure of about the $\frac{1}{70}$th of a second the legs appear to move in threes diagonally, for instance, the 3rd, 4th, and 5th, and the 9th, 10th, and 11th on one side move simultaneously with the 6th, 7th, and 8th of the other side, while on the first side mentioned the 6th, 7th, and 8th, with the 12th, 13th, and 14th are on the ground, and on the other side the 3rd, 4th, and 5th, and 9th, 10th, and 11th are also on the ground. At either end of the body this order is usually more or less disturbed; thus on the right side the 14th leg might be on the ground, while on the left the 13th, 14th, and 15th would be also in contact with the ground; but

in none of the photographs was the symmetrical diagonal movement of the successive threes disturbed between the 2nd and 12th pairs of legs inclusive. This apparently simultaneous motion of three adjoining legs may probably be explained by supposing a series of waves, whose crests traverse three legs in the $\frac{1}{70}$th of a second, to be passing along the body, since the different photographs show different legs moving in threes; thus in one photograph the 6th, 7th, and 8th on the left side are seen to be moving forward, while in another the 5th, 6th, and 7th, are moving.

Since reading the paper at the Royal Dublin Society, Mr. G. H. Carpenter brought to my notice two papers by M. Jean Demoor, "Recherches sur la Marche des Insectes et des Arachnides" (*Archives de Biologie*, 1890) and "Recherches sur la Marche des Crustacés" (*Archives de Zoologie Expérimentale et Générale*, 1891). M. Demoor points out the simultaneous use of the tripod in the insects which he examined, but as he did not use photography he does not seem to have observed the minute want of synchronism of the legs of a tripod. Figs. 4 and 5 illustrate this.[1] These are two photographs taken of the same specimen of *Blaps mucronata*. Fig. 4 is from a photo-

FIG. 4.

graph taken with a long exposure, and shows the 1st and 3rd of the left side, and the 2nd of the right moving at the same time, just as it appears to the eye. Fig. 5 is from

FIG. 5.

a photograph taken with less than half the exposure of 4, and shows that while the 1st leg on the right side is raised off the ground, the 3rd on the same side and the 2nd on the left have not yet been raised. That they have not been raised and are now come to rest is shown by their backward position with regard to the body and other legs. These two photographs also show that the antenna is often twitched almost simultaneously with the motion of the 1st leg of its side. M. Demoor also observed a scorpion (*Buthus australis*), but its method of progression does not seem to have agreed with that of the scorpions (*Buthus europæus*) which I observed. He has not, so far as I know, recorded any observations on spiders.

HENRY H. DIXON.

Trinity College, Dublin, June.

[1] Figs. 4 and 5 show the legs, which are raised from the ground, quite sharp. In the negative they are more or less blurred owing to their motion during the exposure.

ON IRON ALLOYS.

THE merely mechanical expert in the working of metals would naturally consider it probable that a given metal when fused with another would communicate its physical properties, roughly, in proportion to the quantity added. A soft, tough metal added to iron would, from his point of view, render the latter softer; a brittle or hard metal would have the contrary effect, and so on throughout the whole series of metallic alloys.

Actual experiment would soon, however, show the fallacy of this, and that in the majority of cases no reliance could be placed on this assumption solely based on the physical properties of the elements severally considered. A further study of the laws which govern chemical combination would quickly show that alloys formed by fusion were not merely intermixtures, but that something else took place, bodies being often produced, or rather formed, differing considerably from the metals severally used. It would therefore be fair to assume that the metals entered into combination with each other, and yet it would be found that the problem even at this stage was not completely solved.

Further inquiry and experiment would indicate that it was not always possible to prove that chemical combinations "were in all instances" formed by fusion alone. Instead of this something closely akin to only an intermixture of the metals occurred; second, one of the metals had apparently dissolved in the other; third, it was difficult to differentiate betwixt intermixture and solution. Here we are on all fours with modern ideas which seem to have met with general acceptance, although it is not denied that elements or metals are capable of chemically combining with each other. We are not, however, quite prepared to draw a hard and fast line betwixt chemical combination of the metals with each other, solutions, and intermixtures of metals. One appears to merge into the other, and no good reason "so far as is known" can be given why solution, as ordinarily understood, or as defined by Van 't Hoff and others, may not be as applicable to fused metals as to the solution of certain salts in water.

Water at 60° is nothing more nor less than fused ice; fused iron, therefore, may obey the same laws, and, "like water," may be capable of dissolving certain substances, and rejecting others, temperature constituting the sole difference—or plainly, solid ice is fusible at 60°, iron at about 2500°.

Now what happens in the case of water? Certain bodies are soluble in it, others not; on lowering the temperature, these bodies are to a certain extent rejected, and nearly, but not quite, pure ice is formed; and so far as we know this equally applies to fused iron. As an instance, on cooling, the carbon is rejected, and appears in the graphitic[1] form, merely diffused throughout the solid cold metal. It is impossible here to treat this matter in detail; but enough, we think, has been said to indicate that the analogy is fairly complete throughout.

But there is another matter—apart from the solution of foreign bodies in fused ice or iron—which requires to be discussed. Ice dissolves in warm water, and so does cold iron or steel in superheated fused iron; the hot fluid metal from the Bessemer converter fuses or dissolves large lumps of solid steel placed in it as easily as ice is thawed in warm water. Temperature here, in both instances, determines the quantity which can be added; the higher the heat, the greater the quantity which can thus be dissolved or fused, ere the bath becomes thick, pasty, and incapable of being poured out into another vessel.

In so-called solutions the same rule appears to hold good; but, as all chemists know, there are many exceptions; in some cases heat is evolved, in others absorbed, and some bodies are more soluble in the cold fluid solvent.

It is, however, believed that no instance can be quoted of a body being more soluble in iron at a low degree of heat than at a high one. Confining ourselves to hot fluid iron or steel, it apparently readily dissolves cold metal. Similarly, other bodies, such as copper, &c., are dissolved in the same way when added to it.

The cold metal is fused by absorption of the enormous

[1] The relations existing betwixt carbon and iron are peculiar, and require to be separately discussed.

extra heat of the bath, but this may not be strictly true, for something like solution may also take place In melting iron in the reverberatory furnace it often happens, when the heat is insufficient, that the iron sets in a pasty semi-fluid mass on the bottom of the furnace, the operator then adds some molten iron, and the whole soon becomes fluid

This process is closely akin to solution It cannot be explained as simple fusion of iron in iron, the molten iron, in fact, seems to exert a solvent action on the pasty metal, and heat alone plays only a secondary part This may seem absurd to those not practically engaged in the manufacture of iron, but the fact remains as the result of the experience of iron-workers.

It follows that other metals can be similarly taken up, and the theory of certain iron alloys simplified There are certain metals intimately related to iron on the periodical scale of the elements, also by atomic volume and atomic weight, and their combination with iron may be achieved by fusion, and possibly something like solution as well, as described, resulting in the production of a similar homogeneous product, which compound metal cannot well be termed either a solidified solution of one metal into another, a chemical combination, or intermixture of metals The physical properties of this alloy, of course, are different from those of iron This seems an extreme view to take, but it may be mentioned that the absolutely pure elements prepared by special experts are known in some instances to differ somewhat from those accepted as such in an ordinary laboratory It has been also noted that the so-called impurity extracted does not differ very greatly from the pure product, and yet is not precisely the same—(quoting from memory, "this applies especially to alumina," why not iron?)

As the result of an extensive experience in the chemical examination of crude iron, steel, and the purest wrought iron, one finds that some metals cling persistently to iron—manganese is always present, nearly all contain copper, nickel also may often be detected if sought for, chromium is not so rare a constituent as might be supposed—all, however, in minute quantities in the case of wrought iron or Bessemer decarbonized metal

It is curious that these particular metals should cling to iron, but the previous exposition of their relation to iron possibly affords a clue accounting for their persistent presence.

Again, one gathers from a study of Crookes's theory of the genesis of the elements, together with his spectroscopic researches on the composition of the rare earths, yttria, &c, that one so-called element apparently merges into another by almost insensible gradations, it is probable that iron is one of these Probably it is, for recently it has been all but demonstrated by Prof Roberts-Austen and others that iron is a compound body, but the relations betwixt these bodies are so close that they have not been isolated, and both are still termed iron

We have evidence of the possibility of one element merging into another and that iron is not an element, and any one who has studied the periodic law cannot fail to see at least the probability that minute variations in the composition of the elementary bodies may occur, which, however, cannot well be differentiated by our present comparatively coarse analytical methods Modern methods, however, have been sufficiently accurate to enable us to show that certain relations can be traced throughout the whole series of the elements, and it is in this way that the periodic law has been formulated; and fairly trustworthy atomic weights have been obtained

Admitting the possibility of minute variations in the composition of elementary bodies, or more correctly that, as urged by Crookes, an element may have more than one atomic weight—the atomic weight accepted being the mean of these: with the periodic law for our guidance, and also attaching due weight to the relations existing betwixt the weights and volume of the atoms, it would seem that the theory advanced of the homogeneous formation of bodies by fusion is in accord with the periodic law, &c, governing the genesis of the elements.

This is equivalent to saying that a fourth state of combination may be imagined, which is—

(1) Neither solution of one metal in another
(2) Chemical combination of bodies
(3) Intermixture of bodies

Hadfield's alloys of iron and manganese may be members of this class

The first series of these alloys are hard, but when the manganese exceeds 7 per cent the metal softens and alloys containing about 12 to 15 per cent of Mn are strong, tough, cannot be annealed, and cannot be termed either iron or steel.

The same to a certain extent, it is believed, applies to the nickel alloys of iron

There are other properties, which show that the FeMn alloys are unique

The alloys of chromium and iron recently made by Mr Hadfield appear to be of the same class, as also those of nickel and copper with iron

More plainly, the homogeneous compound bodies previously commented upon may be practically termed elementary bodies similar to the quasi-elements of the rare earths studied by Prof Crookes These being, however, within the domain of practical chemistry, it is easy to demonstrate their compound nature, not forgetting "that, as previously noted," it is not easy to entirely eliminate these bodies allied to iron

We may even go further and assume that the fourth state indicates a species of combination even more intimate than the chemical combination of the chemists

In fact, reactions "occur quite unlike chemical combination in which atoms only combine with atoms, or bodies are built up atomically" The fourth state may go beyond this, at present this is pure assumption, yet an eminent man of science has suggested that even the atoms may be *smashed*, and this is equivalent to saying that under certain conditions the atom may be nonexistent, or in an alloy of, say, iron and nickel or iron and manganese, the separate atoms of iron and manganese do not exist, or in an alloy of iron and Mn or nickel, the severally separate atoms of Fe and Mn, &c., may have no tangible existence apart from each other, as in the case of true chemical combination Further, this seems more probable if we remember that chemical combinations are, according to modern views, nothing more nor less than structural formations governed by physical laws which regulate their molecular arrangement and the relative positions of the atoms to each other, just as in any structural work built by the hand of man, certain laws or rules must be adhered to In Nature's laboratory something beyond this may be going on—something, indeed, altogether outside our limited knowledge and experience

Iron is only one member of a very complicated group, which are closely in accord both as regards their atomic volumes and weights and position on the periodic scale of the elements, and, if we are to accept the work of Prof. Crookes, the well-known investigations of Prof Roberts-Austen, Osmond, and some data derived from the spectroscopic work of Lockyer, one may be really justified in assuming that quasi-elements may be formed by fusion in the workshop—*i.e.*, elements which can afterwards be dissociated by ordinary chemical processes The accepted elements, it is true, have not been so dissociated; but it is clear something has been done to indicate the compound nature of at least some of these

The theory of the possible existence of iron as a quasi element when fused with other elements of like nature clashes with the generally received ideas of chemical

combinations or solution, because undoubtedly these are formed.

Granting that chemical combinations likewise take place, does it not seem probable that when these latter are present they may be strictly termed impurities?

If so, iron alloys may be divided into two classes—(1) those in the homogeneous or fourth state, "the true alloys," (2) those in which chemical combinations or solution only takes place, and this latter class may be termed impure metal, in contradistinction to the first or quasi elementary body.

In conclusion it is urged that many of our most eminent metallurgists and men of science have "by very different modes of investigation" come to the conclusion that iron itself is a compound very complex body. It is true that we have only indirect proof of this, but it only remains to find methods of isolating these bodies from each other.

NOTES

THE medals of the Royal Society are this year awarded as follows:—The Copley Medal to Prof. Rudolph Virchow, For. Mem. R.S., for his investigations in Pathology, Pathological Anatomy, and Prehistoric Archæology; the Rumford Medal to Mr. Nils C. Dunér, for his Spectroscopic Researches on Stars; a Royal Medal to Mr. John Newport Langley, F.R.S., for his work on Secreting Glands, and on the Nervous System; a Royal Medal to Prof. Charles Pritchard, F.R.S., for his work on Photometry and Stellar Parallax; the Davy Medal to Prof. François Marie Raoult, for his researches on the Freezing Points of Solutions, and on the Vapour Pressures of Solutions; the Darwin Medal to Sir Joseph Dalton Hooker, F.R.S., on account of his important contributions to the progress of Systematic Botany, as evidenced by the "Genera Plantarum" and the "Flora Indica," but more especially on account of his intimate association with Mr. Darwin in the studies preliminary to the "Origin of Species." The award of the Royal Medals has been graciously approved by the Queen.

THE American Ornithologists' Union has been holding its tenth congress at Washington. The meetings began on Tuesday, and were held in the U.S. National Museum.

JAMES PLANT, F.G.S., of Leicester, who has just died in his seventy-fifth year, was well known as a local geologist in the midland counties, and as a member for some years of the Committee of the British Association on Erratic Blocks. Such blocks are numerous in Leicestershire, those on the southern side of the county being chiefly derived from the Charnwood range, and Mr. Plant was diligent in searching out and recording the more important of them. Several large boulders striated and partially polished stand in the grounds of the Leicester Museum, rescued by him from various railway cuttings. In 1868 he collected a very fine series of massive specimens representing all the hard rock formations of his native county, for exhibition at the meeting of the Royal Agricultural Society. These were afterwards built up into a great cone about 8 feet in diameter and 15 feet high in the museum grounds, and when the enlargement of the building necessitated its removal they were formed into a diagrammatic geological section on another site. Having to be again removed two years ago some of them were used to form a rough geological model of Charnwood Forest in the Abbey Park. In his latter years Mr. Plant acted as consulting geologist in several important borings for water and coal. The curious concentric rings on the face of a rock in Charnwood Forest interested him greatly, and with much trouble and labour he succeeded in obtaining plaster casts of them. He was active also in procuring photographs of many of the most remarkable geological features of the district.

DR. R. v. WETTSTEIN, of Vienna, editor of the *Oesterreichische Botanische Zeitschrift*, has been appointed ordinary Professor of Botany at the University of Prague.

THE Prussian Government has decided to introduce the use of the Centigrade thermometer instead of that by Reaumur, which is still in use in some parts, and no further Reaumur thermometers are to be supplied to any public officials. The Centigrade thermometer has long been in use in Germany for scientific purposes.

A VALUABLE collection of fossils, minerals, and shells, comprising several thousand specimens, and particularly rich in specimens from the carboniferous formation, has just been presented to the University College of North Wales by Mr. Evan Roberts, of Manchester. It is hoped that this gift will become the nucleus of an important geological collection suited to the educational requirements of a University College, and that similar gifts will from time to time be made to the College by those interested in the progress of geological study.

THE Oxford Medical Society held its first meeting on Saturday last, at the University Museum. Sir Henry Acland presided. The inaugural address was delivered by Sir James Paget. He said they all knew that the practice and science of medicine, or, as it was sometimes called, the science and art of medicine, were by some regarded as things quite distinct, wide apart, and in study almost incompatible. A few there were who had the capacity of pursuing both. The great mass of those engaged in the pursuit of medicine were either practitioners or men devoting themselves to science. Each method of work was essential to the practice of the other. It might be asked how could practitioners work as men of science even where they had the time for it? He believed that would come about by the increase in the teaching of science in all medical schools and Universities. He pointed out the work which might be undertaken by the society, and spoke at length on various subjects which might be studied with advantage. Prof. Burdon-Sanderson said the society had been established for the furtherance and promotion of science, and they wished to make an advance, so to speak, towards the University. There was a yearning in the minds of the medical profession in Oxford to unite itself more closely than it had hitherto with the scientific studies of the University which depended immediately on medicine.

THE weather has continued very unsettled during the past week, the most notable features being the prevalence of fog and abnormally high temperature. During the latter part of last week fog extended over nearly the whole of England, as well as a large part of the Continent. In London and the suburbs intense darkness occurred on several days, interspersed with very short intervals of sunshine, but in the north western parts of the kingdom the weather was generally fair. These conditions were due to the distribution of pressure, which was cyclonic over the western portion of these islands, but anti-cyclonic over western Europe. Temperature was uniformly high for the season, the daily maxima ranging from about 50° to 60°, and reached 62° in several places in the southern counties on Monday. This maximum is the highest that has been recorded in the neighbourhood of London during the last ten years. In the early part of the present week a deep depression passed to the westward of Ireland from the Atlantic, causing southerly gales in the north and west, with rain in all parts of the country, the amount measured at Valencia Observatory on Monday exceeding an inch. On Tuesday afternoon a fresh depression reached our south-west coasts from the south-eastwards, while a trough of low pressure lay over the Bay of Biscay and France, causing further heavy rains and local fogs. For the week ending the 12th instant the reports show that bright sunshine was, as might have been expected, very deficient generally, especially over northern and eastern England, where the percentage of possible duration was only 9; the lowest

amount was at Stonyhurst, where it was only 2 per cent The south-west of England enjoyed the brightest weather, as there the sunshine amounted to 33 per cent of the possible amount

THE current number of the *Annalen der Hydrographie* contains a short note of a hurricane at Marseilles on October 1, which is said to have been more severe than any experienced during the last thirty years From 8 a.m until 1 p m the wind, rain, hail and lightning were incessant, all the lower parts of the town being under water, while several houses and bridges in the neighbourhood were destroyed The weather charts for the day show that the storm was caused by a small whirl which occurred on the south eastern side of a large depression, whose centre lay in the south of Scotland While the centre of the depression scarcely altered its position, the whirl increased in extent, but diminished in intensity, and on October 3 it had crossed Northern Italy and lay over Hungary

MR. CHARLES CARPMAEL, director of the meteorological service of the Dominion of Canada, urges in his latest report the need for more thorough inspection of the various stations under his control He points out that the stations in Great Britain and Ireland, connected with the Meteorological Office, London, are constantly inspected, and that in every country where meteorology is worked out on a large scale inspection is admitted as the only system whereby trustworthy and satisfactory results can be obtained. He recommends therefore that a sufficient appropriation should be placed at his disposal to enable him to have the meteorological stations in the Dominion inspected and the observers thereof thoroughly instructed in the duties required of them If this is not done the data furnished to the Central Office cannot, he says, be accurate

TWO numbers have now been issued of the new series of the quarterly cryptogamic journal, *Grevillea*, under the editorship of Mr G Massee. It is conducted very much on the old lines, and contains many articles of interest to cryptogamists It is strange that one peculiarity of the journal should still be retained which detracts very much from its usefulness as a work of reference, the absence of any table of contents or index to each separate number.

THE Cambridge University Press has issued the Sedgwick prize essay for 1886, by the late Thomas Roberts, on the Jurassic rocks of the neighbourhood of Cambridge The essay has been edited by Mr Henry Woods, Scholar of St John's College, and Lecturer on Palæontology in the Woodwardian Museum In an interesting preface, Prof. T McKenny Hughes explains the nature of the problem which the author endeavoured to solve, and expresses his belief that the work is indispensable for the student of Cambridge geology, and most valuable for all specialists in the Jurassic rocks.

SIR HENRY H. HOWORTH has completed and will shortly publish a considerable work on which he has been long engaged entitled, "The Glacial Nightmare and the Flood." It begins with an account of the various theories which have been forthcoming to explain the drift phenomena, in which the very large literature on the subject has been for the first time condensed and tabulated. It then proceeds to criticize the extreme glacial views which have recently prevailed among geologists, and to call in question the theory of uniformity as developed by the followers of Lyell and Ramsay, and especially to attack the notion that ice is capable of distributing materials over hundreds of miles of level country, and of producing many of the effects attributed to it by the glacial school of geologists. The author argues that the evidence points to the former existence of much larger glaciers than exist now, but not to an ice/period when the temperate regions were covered with ice. On the contrary, these great glaciers existed side by side of fertile plains. Lastly he argues that the phenomena of the drift can only be explained by reverting in a large measure to the diluvial theories of Sedgwick and Murchison, Von Buch and others, and that the purely geological evidence is completely at one with that collected in the author's previous work on "The Mammoth and the Flood," and establishes that a great diluvial catastrophe forms in the temperate zones the dividing line between the mammoth age and our own

THE Libraries Committee of the Glasgow Town Council, in the eleventh general report on the Mitchell Library, Glasgow, make a suggestion which deserves to be kept in mind It is to the effect that an admirable way of perpetuating the memory of a relative or friend would be to present a public library with a separate collection of books, to be kept together and called by such name as may seem proper to the donors "Such a memorial collection," say the Committee, "would, with propriety, be composed of books devoted to any department of literature or learning in which the person to be commemorated was interested or which the donors desired to see more fully represented"

A VALUABLE paper on the present state of Morocco is contributed to the current number of the *Revue Scientifique*, by M A Le Châtelier He brings out very strikingly the mixed character of the population of Morocco. First he notes the fair-haired, blue-eyed type, which is represented in the sculptures of some tombs of the twelfth Egyptian dynasty Then come the various Berber types, the Arabs, several elements (including the Draoua) which have come down from remote antiquity, Spanish Moors and Jews, and the descendants of Christian captives. M Le Châtelier thinks we must also take into account descendants of Phenicians, Carthaginians, Romans, Byzantines, and Vandals.

Mr C H EIGENMANN has contributed to the Proceedings of the U S National Museum (vol xv) a paper in which he presents a valuable account of the observations made by him on the fishes of San Diego and vicinity from December 11, 1888, to March 4, 1890 Especial attention was paid to the spawning habits and seasons, the embryology, and migration of the fishes of Southern California. A diary was kept of the occurrence of each species throughout the year 1889 and part of 1890 Mr. Eigenmann's knowledge of the occurrence of each species is largely based on observations of the fish brought into the markets, which he visited twice or thrice daily, and of those caught with hook and line by the numerous habitual fishermen found on each of the wharves, and of those caught by the seiners, whom he accompanied on several occasions During the early part of 1888 each individual fisherman sold his catch as best he could and the data for this part of the year are not as full as for the latter part of 1888, when practically the whole catch was brought to two markets, where Mr Eigenmann could see the fish as they were unloaded The knowledge of the ocean fishes is largely derived from frequent visits to ocean tide-pools, from the fish brought to the markets, and from a two weeks' stay on the Cortes Banks As a matter of course, hundreds of specimens of most species have been observed to every one preserved, and the present paper is to be looked upon as a contribution to the economic history of the fishes, rather than to the anatomy of the various species With two exceptions, the types of the new species discovered, and otherwise interesting specimens, have been deposited in the U S. National Museum A nearly complete series of types has been placed in the British Museum, and minor series in the Museum of Comparative Zoology and the California Academy of Sciences.

THE Committee of the Field Naturalists' Club of Victoria have hit upon an excellent plan for interesting the more active members in definite lines of investigation They have arranged that special meetings shall be held once a month for the carrying on of practical work which cannot conveniently be undertaken

at the ordinary monthly meetings. The first of these special meetings assembled on August 22 in the Royal Society's Hall, Melbourne We learn from the Club's journal that there was a good attendance of members, those interested in microscopic work being principally represented. No fewer than twenty-four microscopes were set up Mr J Shephard undertook to give a slight sketch of some interesting forms amongst the rotifera. A typical form was first described, the chief points in its structure being made clear by good diagrams, and then variations in the various orders from this type were briefly referred to—special allusion being made to the modifications in the ciliary wreath and the foot. Mr Shephard had fortunately met with a large number of the Australian member of the rhizotic group (*Lacinularia pedunculata*), and at the conclusion of his remarks a slide of mounted individuals was handed to each member for careful examination under the microscope Half an hour was profitably spent in the endeavour to make out all the points of detail in the specimens, during which time Mr Shephard also supplied full information as to the best methods of mounting and examining these interesting organisms Some four or five entomologists had a quiet corner to themselves, where they compared specimens and talked over some plans for future operations

AT the ordinary monthly meeting of the Field Naturalists' Club of Victoria, on September 12, the feather boots of a native rain-maker from M'Donnell Ranges were exhibited It is believed among the natives of certain tribes in Central Australia that droughts are caused by the swallowing up of all moisture by a rain-devil If this personage can be captured and made to disgorge, rain follows at once. The feather boots are worn by the native rain-maker in order that he may steal noiselessly and unawares on the author of the drought and consequent misery Mr A W Howitt is having drawings made of these boots, which he considers to be one of the most valuable and interesting additions to aboriginal ethnology yet brought to light

AN interesting paper on the anthropology of Spain, contributed to the "Anales" of the "Soc española de Historia Natural" by Luis de Hoyos Sáinz and Telesforo de Aranzadi, has now been published separately at Madrid The paper is accompanied by three excellent maps, in which, by means of various degrees of shading, the authors bring together a number of most interesting conclusions One of these maps shows the cranial types which prevail in different parts of Spain

IN the November number of the *Mediterranean Naturalist*, Mr John H Cooke gives an interesting account of his recent discovery of Ursus arctos in the Malta Pleistocene The late Admiral Spratt and the late Prof Leith Adams found among the cavern deposits of the Maltese Islands a remarkable land fauna, including elephants, hippopotami, land tortoises, gigantic dormice, and aquatic birds. From the fact that many of the remains of elephants presented the appearance of having been fiercely gnawed, it was concluded that carnivoræ had lived in the district, but, notwithstanding the most diligent search extending over a period of twenty years, the only tangible evidences in support of the inference were these gnawed bones Mr. Cooke has now solved the problem His discovery was made in the spring of the present year, when, with the aid of a money grant from the Royal Society, he carried out some excavations in the Har Dalam cavern, a subterraneous gallery situated in a gorge of the same name in the eastern extremity of Malta. After having excavated six large trenches and obtained some hundreds of bones of *Hippotamus pentlandi*, *Elephas mnadraensis*, *Cervus barbaricus*, and numerous other animals, he had the satisfaction of discovering an entire ramus of the lower jaw of a bear, Ursus arctos with its canine and molars *in situ*, as well as five other canines belonging to other individuals of the same species. Afterwards four other canines were discovered, each of which was in a fairly perfect state of preservation One of these Mr A S Woodward has determined as belonging to the left side of the mandible of a species of *Canis* equalling a wolf in size Associated with these remains were found several vertebræ and fragments of limb-bones of hippo, and vertebræ and portions of horns of stags; but none of them presented any evidences of having been gnawed

THERE is some difference of opinion as to whether the process of digestion is promoted or hindered by bodily exertion Herr Rosenberg recently made some experiments on a small dog with reference to this point (*Pflüger's Archiv*). The animal was fed once daily with a certain quantity of lean horseflesh, lard, and rice, and the amount of nitrogen and fat daily absorbed was determined by an examination of the excreta. There were five series of experiments, each consisting of a rest period of several days, followed by a working period of several days, the dog being made to work in a kind of treadmill In some cases these efforts were made during stomachic digestion, in others during intestinal In both series of experiments the differences observed lay within the limits of physiological variations, the inference being, accordingly, that in a healthy dog the utilization of food is quite independent of whether the animal rests during digestion or is energetically at work Whether this applies to man could only be determined by direct experiment Herr Rosenberg thinks it probable, however, as observations on people with heart disease appear to show that the absorption of food is to a certain extent independent of the circulation and distribution of the blood

THE characteristic mantle of ascidians, consisting of a ground mass with cellulose and embedded cells, has been much studied, especially with regard to the origin of the cells The most favoured view is that it is produced by the ectoderm, that it is a thickening of the outer epithelium Recent researches by Kowalevsky, however (described to the St Petersburg Academy) give reason for believing that the mantle-cells are from the mesoderm Studying the metamorphosis of *Phallusia mamillata*, he observed certain mesoderm-cells applying themselves to the ectodermal epithelium, penetrating it and entering the mantle, which (secreted from the ectoderm) was before quite transparent These cells also move freely about in the mantle, and this amœboid movement is further in favour of their mesodermal nature A similar process occurs in vertebrates, viz., the passage of lymph-cells (leucocytes) through epithelium to the surface of a mucous membrane, or the surface of the body (in fishes), the mucous layer is comparable to the ground mass of the mantle But in vertebrates the cells at length disappear, whereas in ascidians they persist. Besides their share in the growth of the mantle, they have an important function as phagocytes. In compound ascidians certain individuals are every now and again perishing, and these dying parts are known to be absorbed by the mantle cells. Also, incoming foreign bodies, such as bacteria, the cells attack and seek to destroy. Numerous bacteria are always present in the mantle of tunicata Moreover, experiments were made by introducing bacteria through fine glass tubes inserted in the mantle; the mesoderm-cells collected round these tubes, entered them, and fought with the bacteria. Kowalevsky attaches great importance to this function, and supposes the above-mentioned passage of wandering cells to the surface of epithelia to be explained as a means of protection against the intrusion of agents of disease.

MR. L. STEJNEGER gives in the fifteenth volume of the Proceedings of the U S. National Museum an interesting preliminary description of a new genus and species of blind cave salamander from North America. The discovery of a blind cave salamander in America is regarded by Mr Stejneger as "one of the

most important and interesting herpetological events of recent years." The discovery is primarily due to Mr F A Sampson, who, in July last year, found the adult animal as well as a larva in the Rock House Cave, Missouri, and forwarded both to the U S National Museum Mr George E Harris afterwards went to great trouble in order to procure additional specimens Unfortunately, he has only succeeded so far in obtaining larvæ, but Mr. Stejneger hopes to be able to secure more adults A more detailed anatomical description of this interesting animal is postponed until then, as he has not felt justified in mutilating the type specimen beyond what was necessary in order to ascertain the character of the vertebræ The present preliminary description is, therefore, only prepared in order to call attention to the discovery and to supply the diagnosis by which the animal may be identified.

DR MORRIS GIBBS contributes to *Science* an interesting paper on the food of humming-birds He has carefully dissected many humming-birds, both old and young, but has never found anything to convince him that the birds live on insects It may be that at times when flowers are scarce some species of insects are captured, but Dr Gibbs is satisfied that in season, when flowers are abundant, the ruby throat of Michigan lives on honey.

IN a recent investigation of the action of accumulators, Herren Neumann and Streintz have shown (*Wied Ann*) that lead has the power of absorbing hydrogen In one case the metal was used as an electrode, and charged with electrolytic hydrogen, in another it was melted, and a current of hydrogen passed through it Care must be taken that the charged metal is not in contact with air, as the oxygen of the latter then unites with the hydrogen, and this, the authors think, is why previous observers have not been able to prove an occlusion of hydrogen by the lead plates of accumulators The authors examined other metals, and they give the following numbers for the gas absorbed per unit volume of metal —Lead, 0 15, palladium, 502 35, spongy platinum, 29 95, platinum black, 49 30, gold, 46 32, silver, 0 00, copper, 4 81, aluminium, 2 72, iron, 19 17, nickel, 16 85, cobalt, 153 00 When the same pieces of metal were repeatedly used, the occluding power generally fell off, in the case of the noble metals this is thought to be due to increased density, but why the occluding power of iron and cobalt should be reduced to one-half or more was not explained Nickel and copper retained their power With regard to the high power of cobalt, the authors tried that metal in a voltameter, but curiously it showed no hydrogen polarization when the charging circuit was opened.

MESSRS. WILLIAMS AND NORGATE's Natural Science Catalogue (No. 9) includes classified lists of books and periodicals on mathematics, astronomy, meteorology, physics, electricity, chemistry, microscopy, optics, mechanics, engineering, technology, &c., in French, German, and other foreign languages

THE opening meeting of the one hundred and thirty-ninth session of the Society of Arts was held yesterday (Wednesday) evening. The following arrangements have been made for the ordinary meetings:—November 23, "The Disposal of the Dead," by F. Seymour Haden, November 30, "The Copper Resources of the United States," by James Douglas, December 7, "The Chicago Exhibition, 1893," by James Dredge; December 14, "The Utilization of Niagara," by Prof. George Forbes, F.R.S. The following papers, for which dates have not yet been fixed, will be read — "Transatlantic Steamships," by Prof. Francis Elgar, "The Detection and Estimation of Small Proportions of Inflammable Gas or Vapour in the Air," by Prof. Frank Clowes, "The Purification of the Air Supply to Public Buildings and Dwellings," by William Key; "Pottery Glazes: their Classification and Decorative Value in Ceramic Design," by Wilton P Rix, "The Chemical Technology of Oil Boiling, with a Description of a New Process for the Preparation of Drying Oils, and an Oil Varnish," by Prof. W Noel Hartley, F R S, "The Mining Industries of South Africa," by Bennett H. Brough, "Ten Years of Progress in India," by Sir William Wilson Hunter; "Australasia as a Field for Anglo-Indian Colonization," by Sir Edward N C Braddon, Agent-General for Tasmania, "Indian Manufactures," by Sir Juland Danvers, late Public Works Secretary, India Office, "Caste and Occupation at the last Census of India," by Jervoise Athelstane Baines, Imperial Census Commissioner for India, "Mexico, Past and Present," by Edward J Howell, "Newfoundland," by Cecil Fane "New Zealand," by W B Percival, Agent-General for New Zealand. The following courses of Cantor lectures will be delivered on Monday evenings, at eight o'clock Prof Vivian Lewes, "The Generation of Light from Coal Gas" (four lectures, November 21, 28, December 5, 12), Dr J A Fleming, "The Practical Measurement of Alternating Electric Currents" (four lectures, January 30, February 6, 13, 20), Prof W Chandler Roberts-Austen, F.R S, "Alloys" (three lectures, March 6, 13, 20), Lewis Foreman Day, "Some Masters of Ornament" (four lectures, April 10, 17, 24, May 1), C Harrison Townsend, "The History and Practice of Mosaics" (two lectures, May 8, 15) A special course of six lectures, under the Howard bequest, will be delivered on the following Friday evenings at eight o'clock Prof W C Unwin, F R S, "The Development and Transmission of Power from Central Stations" (January 13, 20, 27, February 3, 10, 17)

THE additions to the Zoological Society's Gardens during the past week include a Squirrel Monkey (*Chrysothrix sciurea*) from Guiana, presented by Mrs K Betts, a Brown Capuchin (*Cebus fatuellus* ♀) from Brazil, presented by Miss L. Blackburn, a Himalayan Bear (*Ursus tibetanus* ♀) from Burmah, presented by Major W H Cunliffe, a Herring Gull (*Larus argentatus*) British, presented by the Rev Sidney Vatcher, a Goshawk (*Astur palumbarius*) captured at sea, presented by Capt F Manley, an Egyptian Vulture (*Neophron percnopterus*) from Africa, presented by Mr J L. Teage, two —— Buntings (——) from North Africa, presented by Lord Lilford, F Z S, eighteen Filfola Lizards (*Lacerta muralis* var *filfolensis*) from the Island of Filfola, eighteen Wall Lizards (*Lacerta muralis* var *tiliguerta*), an Ocellated Sand Skink (*Sepsocellatus*), a Moorish Gecko (*Tarentola mauritanica*), a Turkish Gecko (*Hemidactylus turcicus*) from Malta, presented by Capt Robert A Threshie; a Common Kite (*Milvus ictinus*) from Spain, received in exchange, five Dingos (*Canis dingo*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE NEW COMET —The weather has prevented observations of the new Comet Its brightness is about that of the nebula in Andromeda, and it has been suggested that it is a return of Biela's Comet

COMET BROOKS (AUGUST 28) —The following is a continuation of the ephemeris of Comet Brooks for the present week, extracted from *Astronomische Nachrichten*, No. 312 —

12h *Berlin M.T.*

1892.	R A app. h. m. s.	Decl app ° ′	Log r.	Log Δ	Br
Nov. 17	10 25 3	−2 35 2			
18	29 40	3 34 7			
19	34 20	4 34·8			
20	39 3	5 35 3	0·0674	9 9568	20 51
21	43 48	6 36·2			
22	48 36	7 37·5			
23	53 27	8 39 0			
24	10 58 20	9 40·8	0·0540	9·9483	22 70

The unit of brightness occurred on August 31

The motion of this comet will be noticed from the above ephemeris to be very rapid in a southerly direction, amounting to about 1° per day

THE LIGHT OF PLANETS —The question as to whether the light of planets is capable of casting shadows must have, especially during the last few months, been in the minds of many, and perhaps many observations have already been made, but unfortunately not published With regard to this question, *L'Astronomie* for November contains two notes, the first of which, communicated by M Marcel Moye on August 30, relates to the planet Mars His observations were made just before the meridian passage and in a room where the light of the planet could enter the open window In this way white paper invisible in the corners of the room was easily distinguished when placed on the wall opposite the window, while one could see well the shadows between the fingers of the hand, placing a newspaper in the light of Mars only the place of the table and the number of the words could be recognized, but not read, as was the case with Jupiter M Moye concludes then that Mars certainly casts shadows, less strong than those of Jupiter but still appreciable

In the note on the light of Venus M Léon Guiot tells us that on August 29, when about to get up to observe Jupiter, he was astonished at the brilliancy of the light that entered his window Observing his watch, which was hanging on the wall, he was actually able to trace its shadow on the wall, for he says that all was visible as in the light of the moon, one could even read the newspaper It was about this time that Venus was constantly seen with the naked eye in full daylight

STELLAR MAGNITUDES IN RELATION TO THE MILKY WAY —Prof Kapteyn is the author of an important memoir, which is published in the *Bulletin du Comité International Permanent* pour l'execution photographique de la carte du ciel, relative to an observed systematic difference between the photographic and visual magnitudes of stars depending on their distance from the Milky Way Prof Kapteyn first noticed that a difference existed in 1890, but in the present paper he presents a preliminary account of the results he has obtained The clichés which have been under examination were exclusively those made at the Cape Observatory for the chart mentioned above In this discussion he has adopted the two following laws (1) that increasing the time of exposure in the proportion of 1 to 2 5, the fraction of a magnitude gained is 0 7, and (2) the atmospheric extinction of actinic rays rises to 2½ above the visual rays Since there is an undoubted difference between the photographic and visual magnitudes, denoting this difference by the symbol Δm, the author commences to investigate whether this quantity is ever equal to zero, that is when the photographic and visual magnitudes are equal, and if so to find the locus of these points Charting the points down on a map and connecting them up by means of curves, the latter are found to follow in a striking manner the path of the Milky Way Table II gives the values of Δm obtained from several clichés, and the positive values lie without exception between these two curves, while the negative ones are situated without Taking into consideration both bright and faint stars, that is stars from the 4th to the 10th magnitude, the author finds that there a strong relation depending on their galalactic latitude exists between them, whether they be even very near or distant from the Milky Way, and the same systematic variation of Δm apparently holds good, being represented by the formula

$$\Delta m = a + \kappa\beta$$

representing the galalactic latitude and $\kappa = -0^m \cdot 0099 \pm 0^m \cdot 0010$.

In seeking for an explanation of the difference, Prof Kapteyn investigates each possible cause singly. His conclusion, to state briefly, amounts to this, that, if one considers the stellar magnitudes given in the "Uranometrique" and in Gould's "Catalogue of Zones" (it is from these two sources that he has obtained the visual magnitudes) to be correct and not subject to systematic errors amounting sometimes to as much as half a magnitude, then it must be concluded that the light of the stars situated in the Milky Way or in its vicinity is much richer in actinic rays than those at considerable galalactic latitudes. We may remark that the publication of this paper has been purposely hurried owing to the importance of the matter therein, but although sufficient observations have not been taken in account for a very rigid investigation, Prof Kapteyn hopes to eliminate many of the difficulties and accidental errors by the discussion of clichés of different regions of the sky, differing in galalactic latitudes, made at equal altitudes, on similar plates, with equal lengths of exposure

THE CANALS OF MARS —The late opposition of Mars, and the re observation of the doubling of the canals has brought forward many theories relative to this very curious phenomenon. There seems to be no doubt now that this doubling is not due to instrumental deficiencies, or even to an optical delusion caused by the fatigue of the eyes, but that it is a real observed fact and therefore requires a rigid explanation Omitting the now well known hypotheses suggested up till quite lately, the most recent is that put forward by M Norman Lockyer and which is recorded in NATURE, vol xlvi p 448 Mr Lebour also (NATURE, vol xlvi, p 611) points out the likeness of these markings to the cracks produced in glass broken by torsion, adding that the chief characteristic features in the Mars' lines are there produced In *Comptes rendus* (No 18) for October 31 M Stanislas Meunier relates another possible cause, and illustrates the phenomenon experimentally The experiment is as follows —He takes a polished metallic surface and on it traces a series of lines and spots, representing as nearly as possible the Martial surface as seen by us, and illuminates it all by sunlight He then stretches at some distance (a few millimetres) from it a fine transparent piece of muslin Looking at the surface through this medium he finds that all the lines and spots are doubled, and, "se germiner par suite de l'apparition, à côté de chacune d'elles de son ombre, dessinée sur la mousseline par la lumière que le métal a réfléchie" A fact observed by M Schiaparelli is that the canals when doubled are not always exactly parallel, and that sometimes there is an "aspect de nébulosité" These and other peculiarities are, according to M Meunier, reproduced by simply undulating the muslin His explanation is that the solar light is reflected from the planet's surface very unequally, that from the continents exceeding that emitted by the deeper parts, seas and canals Although the atmosphere is a limpid one, we are unable to see its motions, but if, as he says, the aerial envelope includes a transparent veil of fog at a suitable height, a contrast would be produced, as was the case with the muslin, by the production of shadows "qui pour une œil placé ailleurs que sur le prolongement des rayons réflechis, à côté de chacune des surfaces peu réfléchissantes, une image pareille à elle" This explanation of the phenomena of shades by reflection if valid should of course hold good for the planet Venus when properly situated, and that it is not observed on the Moon is only another proof that our satellite has no atmosphere

GEOGRAPHICAL NOTES

THE *Revue Française* states that a subterranean town, laid out with regular streets in a series of great caverns, near Karki, on the right bank of the Amu daria, has recently been explored Pottery and metal work were found amongst the ruins, and from the coins and inscriptions seen the town must have been occupied at least as early as the second century B C.

BY the new constitution of the United States of Brazil the seat of government is to be transferred from Rio de Janeiro to a site upon the central plateau where an area is to be marked off as a federal district A scientific mission under Senor Cruls has been appointed to examine the region where the three rivers, Sao Francisco, Tocantins, and Parana, take their rise at an elevation of over 3,000 feet, with the view of finding a suitable site for the new capital.

MR. D J RANKIN communicates to the *Scottish Geographical Magazine* an account of his journey up the Zambesi in 1890-91, with a map of the country between the Zambesi and Shire He found the Zambesi freely navigable for light-draught steamers as far as the Acababassa Falls, more than 300 miles from the sea, the Lupata narrows presenting no difficulty Between Lupata and Acababassa extensive coal deposits occur, and these are sure to become valuable. Beyond the falls after a portage of about thirty miles, the Zambesi is again navigable

to Zumbo, and thence for a distance of 300 miles up the Loangwe river

A NOMINATION to the geographical studentship of £100 in the University of Oxford will be made at the end of Hilary term, 1893 Particulars of the appointment may be obtained from Mr Mackinder, the Reader in Geography

TWO sudden deaths of men known in connection with minor exploration and geographical writing are announced Mr Theodore Child, author of "South American Republics" and other works, died of cholera at Ispahan, and Lieutenant Frederick Schwatka, who has travelled extensively in Alaska, committed suicide in Portland, Oregon

MR PRATT, whose departure for the head waters of the Amazon was announced in this column at the time, has been compelled to relinquish the expedition on account of ill-health, and is now in this country

AT the first meeting of the Royal Geographical Society the certificates of 106 new members, including 15 ladies, were read This is the largest number seeking admission into the society which has yet been proposed at one time

DR NANSEN'S ARCTIC EXPEDITION

DR FRIDTJOF NANSEN opened the session of the Royal Geographical Society on Monday night by a description of his plans for crossing the north polar region, and received a most enthusiastic reception from a crowded audience His scheme involves two separate considerations (1) the direction of the prevailing polar currents, and (2) the means by which these currents can be utilized for transporting an expedition All attempts to reach the pole by Smith Sound, by the east coast of Greenland, and by the north of Spitzbergen have been complicated by contrary currents, the few expeditions by way of Bering Sea, although equally unsuccessful, have had the currents in their favour

Taking into account all the available data, it appears that the polar current between Greenland and Spitzbergen carries southward between 80 and 120 cubic miles of water every twenty-four hours. The Gulf Stream drift may carry 60 or 70 cubic miles of water a day into the polar basin north of Nova Zembla, about 10 or 14 cubic miles daily probably flow in through Bering Strait, and possibly about one cubic mile a day of fresh water pours in on the average from the great Siberian rivers. This comparatively small addition of fresh water must account for the salinity of the Greenland outflowing current being somewhat less than the average salinity of the North Atlantic Theoretically there would thus appear to be a current running from near the New Siberian Islands towards the north of Greenland

The existence of such a current is strongly indicated by the drift of the *Jeannette* from 71° 30′ to 77° 15′ N after being caught in the ice, this drift being northwestward from Bering Strait Again, articles lost on the sinking of the *Jeannette* in the latter position off the New Siberian Islands were found on an ice-floe near Julianehaab, in the south of Greenland. A throwing stick, of a kind made only by the Eskimo of Alaska, was found a few years ago near Godthaab, on the west of Greenland Siberian driftwood is stranded regularly on the coasts of Greenland, and even on the north coast of Spitzbergen These facts can only be accounted for by the theory of an ocean current across the polar basin The evidence of the relative thickness of ice in different parts of the Arctic Sea, and of the occurrence of Siberian diatoms in the mud of ice floes between Greenland and Iceland is strongly confirmatory

Dr. Nansen intends to make the northwesterly current transport him across the middle of the polar basin, and so give him an opportunity for making scientific observations nearer the pole than has ever previously been done. He will sail next June *via* the Kara Sea for the New Siberian Islands, thence work a way as far north as possible, when stopped, he will run into the ice, and await the time when he will be drifted into the open sea again between Greenland and Spitzbergen He has had a ship built in Norway expressly for the voyage. Her form is such as to cause the ice, on closing round, to lift her out of the water, and she will rest upright on its surface. This vessel, named the *Fram* (*i.e.* Forward), is built of very long-seasoned timber, and is more strongly put together than any other vessel of her size The frame timbers are of great thickness, and set close together, so that if all the planking were stripped off the vessel would remain water tight The planking is first a ceiling of pitch pine, alternately 4 and 8 inches thick, then outside two layers of oak, 3 and 4 inches thick respectively, and over all is an "ice sheathing" of from 3 to 6 inches of the hard and slippery greenheart The sides are thus from 28 to 32 inches thick of solid wood The decks are equally strong, and the cabins are planned so as to be isolated by store rooms and coal-bunkers from the sides, while non conducting materials such as cork, felt, and reindeer hair are introduced between the walls or decks and the rooms to guard the crew from cold

The vessel is sharp fore and aft, and both propeller and rudder may be lifted in wells so as to avoid risk of fouling the ice The rudder is deeply immersed when in action, so that floating ice will not touch it Both stem and stern overhang greatly, and are heavily plated with iron to crush and cut through thin ice The length of keel is 101 feet, and the length of deck over all is 128, while the greatest beam (exclusive of ice sheathing) is 36 feet, and the depth 17 feet These proportions are very unusual, but were adopted as the result of experience in other ships With light cargo she will draw 12 feet, and fully loaded 15½, the displacement being about 800 tons She is rigged as a three masted schooner, with square sails on the foremast, and has an engine of 160 indicated horse-power The crow's nest on the maintopmast is 105 feet above the water line, so as to give a wide horizon for the look out Two large decked boats are carried, in either of which the whole crew of twelve men could live if the ship were lost Dogs, sledges, ski, several small boats, canvas for building extra boats on an emergency, and provisions for five or six years are taken A pendulum apparatus is included in the scientific outfit, which is otherwise very complete The ship is fitted with electric light the dynamo may be worked by a windmill when coal can no longer be spared, or as a last resort it can be driven by a capstan arrangement adapted for four men, thus supplying healthy exercise and useful work to one third of the crew, and abundant light to the remaining two-thirds

The duration of the voyage cannot be estimated, as it will entirely depend on the rate of drifting, which must vary considerably from year to year, but judging from the movement of the *Jeannette* relics, two years ought to suffice.

A REMARKABLE CASE OF GEOMETRICAL ISOMERISM

AN exceptionally interesting memoir is contributed to the current number of *Liebig's Annalen* by Prof. Wislicenus of Leipzig, who has latterly identified himself so earnestly with the subject of molecular configuration It has been suspected for some years that there are two isomeric unsaturated acids of the composition C_4H_7 COOH One of these substances exists in the free state in the roots of *Angelica archangelica* and has therefore received the name of *angelic acid* The other compound is found along with angelic acid in Roman oil of cumin and has been termed *tiglic acid* These two acids, moreover, behave so similarly in almost all their reactions with other substances that the conclusion has been rendered inevitable that they must be represented not only by the above formula, but by the same constitutional formula, $CH_3\,CH : C \begin{cases} CH_3 \\ COOH \end{cases}$ That the two acids are not identical, however, was indicated by certain slight differences of behaviour, and Prof. Wislicenus felt convinced that the two were in fact geometrical- or stereo isomers, the difference consisting in a different arrangement of their various radicle groups in space He considers it probable that the nature of the difference may be represented in one plane by the following formulæ.

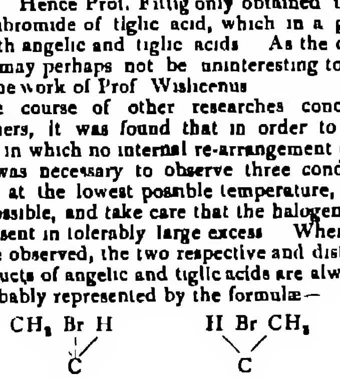
$$\begin{array}{c} CH_3-C-H \\ \| \\ CH_3-C-COOH \\ \text{Angelic acid} \end{array} \quad \text{and} \quad \begin{array}{c} H-C-CH_3 \\ \| \\ CH_3-C-COOH \\ \text{Tiglic acid} \end{array}$$

Judging from previous experience of the behaviour of other geometrical isomers of a similar nature, it appeared probable that the halogen addition products of the two acids would exhibit differences so marked as to determine definitively the separate nature of the two acids. Under the direction of Prof Wislicenus, therefore, one of his pupils, Herr Pückert, undertook the investi-

gation of the bromine addition products of angelic and tiglic acids, and was successful in showing that the two products were essentially different, exhibiting properties indeed so dissimilar that their identity was entirely out of the question. Although their similar constitution was indicated by melting-points differing by only one or two degrees, yet it was found that the crystals of the dibromide of angelic acid immediately reacted with water with production of a colourless oil, whilst the dibromide of tiglic acid remained unchanged in contact with water; moreover, the two compounds upon decomposition of their sodium salts, yielded two mono brom-pseudo-butylenes, which differed essentially in their capability of reacting with alcoholic potash.

In the year 1890, however, Prof. Fittig, of Strassburg, who had previously investigated the subject in conjunction with Herr Pagenstecher, and had obtained *identical* bromine addition products from the two acids, published a paper in the *Annalen* in which he sought to show that the results of Herr Puckert were incorrect, and that the two substances were identical. Prof. Fittig has since requested Prof. Wislicenus to withdraw the work or substantiate it, and further charges Prof. Wislicenus with seeing facts through the veil of his theory. Unfortunately Prof. Wislicenus has been unable hitherto to meet the attack owing to domestic loss and serious illness, but at last he is able to publish the results of a really classical piece of work which he has carried through himself, and which not only demonstrates the truth of Herr Puckert's conclusions, but places the results beyond all criticism, and shows the singular cause of Prof. Fittig's inability to repeat them. It is indeed remarkable, but nevertheless true, that the fate of the theory of geometrical isomerism has actually been trembling in the balance owing to the different situation of the draught cupboards in the Leipzig and Strassburg laboratories. In the former laboratory they are placed *between* the windows, and in deep shadow; in the Strassburg laboratory they are *against* the windows, and are consequently brightly illuminated in daylight. Now Prof. Wislicenus shows that the dibromide of angelic acid is only formed in the absence of bright light, *rays of daylight intensity being absolutely fatal to its formation*. Hence Prof. Fittig only obtained the relatively more stable dibromide of tiglic acid, which in a good light is yielded by both angelic and tiglic acids. As the case is so remarkable, it may perhaps not be uninteresting to give a brief summary of the work of Prof. Wislicenus.

During the course of other researches concerning geometrical isomers, it was found that in order to obtain addition-products in which no internal re-arrangement of atoms had occurred, it was necessary to observe three conditions. One must operate at the lowest possible temperature, exclude light as much as possible, and take care that the halogen to be added is always present in tolerably large excess. When these three conditions are observed, the two respective and distinct bromine addition-products of angelic and tiglic acids are always obtained. They are probably represented by the formulæ:—



Dibromide of angelic acid   Dibromide of tiglic acid

The operation of preparation is best conducted as follows:—A quantity of bromine, at least half as much again as is required by theory, and dissolved in three times its weight of carbon bisulphide, is placed in a flask surrounded by iced water. The flask is fitted with a triply bored caoutchouc stopper, through one hole of which is inserted a thermometer, through a second an exit tube furnished with a calcium chloride drying tube, and through the third the end of a burette containing a solution of pure angelic or tiglic acid in five times its weight of carbon bisulphide. The draught cupboard is darkened as much as possible and then the acid solution is slowly allowed to run into the flask. After the expiration of a few hours the formation of the brominated compound is complete, and the carbon bisulphide may be evaporated away in a rapid stream of dry air.

The difference between the two compounds is apparent even at this early stage, for the tiglic compound commences to crystallize long before the removal of all the carbon bisulphide, and soon forms a snow-white mass of crystals. On the contrary, the angelic dibromide shows no sign of crystallization, remaining as an oil for some time after the removal of all the carbon bisulphide. Eventually it crystallizes to a hard yellowish mass. The only solvent from which it was found practicable to recrystallize the angelic dibromide was the pentane fraction of petroleum ether boiling at 33°–39°.

The melting-point of pure angelic dibromide is 86.5–87°. That of tiglic dibromide is 87.5–88°. The two substances behave quite differently upon resolidification. The former congeals to a transparent resinous mass, whilst the latter forms an opaque solid.

The most striking difference is apparent in their respective behaviour towards water. The dibromide of tiglic acid is only slightly soluble in water, and dissolves unchanged, crystallizing out again upon evaporation. The dibromide of angelic acid, however, instantly combines with the equivalent of one molecule of water, to form a curious unstable liquid, an oil of high refractive power, which is somewhat soluble in excess of water, and is again deposited upon evaporation. This liquid compound is also formed when the dibromide is exposed to moist air, while the dibromide of tiglic acid is not changed in a moist atmosphere. In dry air the angelic liquid compound again dissociates into the dibromide and water vapour. In fact the dibromide of angelic acid would appear to act as an excellent indicator of the hygroscopic state of the atmosphere.

The two dibromides show a further difference in solubility, the angelic compound being far more readily soluble in all the solvents experimented with.

Finally the crystals of the two compounds, although both belonging to the triclinic system, are absolutely unlike. From measurements made by Dr. Fock, they are shown to exhibit different forms, entirely different angles, and different disposition of optic axes.

From the above description it will be quite evident that the two compounds are certainly not identical.

In conclusion, Prof. Wislicenus gives the results of attempts to obtain the dibromide of angelic acid in bright sunshine in the open air, then when working in front of a window, and again when the experiment was performed upon a table in the centre of the laboratory. In the first case, instead of the angelic compound, 92.8 per cent. of the dibromide of tiglic acid was obtained, in the second case 89.6, and in the third case 88.7 per cent. These results render it perfectly clear why Prof. Fittig could not obtain the angelic compound in his experiments, and they also show how it is possible for two chemists, both working with a desire to ascertain the truth, occasionally to obtain results apparently at complete variance with each other.

A. E. TUTTON.

MARINE LABORATORIES IN THE UNITED STATES.[1]

ONLY in comparatively recent times has the tremendous importance of the bearing of the invertebrates upon the general questions of biology been appreciated. We have seen that some work was done upon these animals at an early date, when the minds of workers were not much troubled by theoretical considerations, but the study of the adult forms is so small a part of a real understanding of these animals that it was unsatisfactory work, and never became popular among investigators until embryological methods had been introduced.

Dr. Brooks has remarked that "nearly every one of the great generalizations of morphology is based upon the study of marine animals, and most of the problems which are now awaiting a solution must be answered in the same way."[2] We find the reason for this in the fact that the biology of the present day is a study of vital phenomena and of natural laws governing living things. The importance of the invertebrates depends, therefore, upon the fact that in them life exists under simplified conditions, affording opportunities for the study of questions for which higher forms are, with our present knowledge, too complex.

As the study of invertebrates has extended, it has become more and more desirable to have more favourable conditions for this work, more abundant facilities for collecting and oppor-

[1] Reprinted from "Biological Teaching in the Colleges of the United States," by John P. Campbell, Professor of Biology in the University of Georgia, issued by the U. S. Bureau of Education.

[2] Johns Hopkins University Circulars, vol. vi., p. 37.

unities for studying animals alive Much of the early work was done upon specimens collected and stored in museums, but workers, both in this country and Europe, had frequently made excursions to the seacoast for the purpose of studying the invertebrate forms constituting so large a part of the marine fauna.

The unsatisfactory nature of this work was of course evident Suitable accommodations and working appliances could not be provided under these circumstances, and desirableness of establishing permanent seaside laboratories was early felt Nothing was done, however, in this country until 1871, when John Anderson, a wealthy citizen of New York, presented to Prof Agassiz the island of Penikese in Buzzard's Bay, together with the sum of $50,000 with which to found a seaside station for the study of marine life Another friend gave him a yacht of 80 tons burden for use in collecting Agassiz had long wished for such a laboratory, and no one but himself could have aroused the necessary enthusiasm for carrying out the project He soon set to work and built large laboratories, with suitable accommodations for a large number of workers In 1873 they were opened for work This constituted the first opportunity enjoyed by American students of studying marine animals in their native waters, with proper appliances for work It inaugurated a new era in scientific research, being the first outward expression of an idea which has since taken a firm hold upon the investigators of the country The death of Agassiz in December, 1873, put an end to the project. The buildings were used but two seasons and then abandoned

Of this laboratory Prof Whitman says —

"At the close of the second and last season at Penikese, in 1874, Alexander Agassiz appealed to the colleges and all interested boards of education for support, but all in vain, for not a single favourable reply was received, and so his intention to remove the laboratory to Wood's Holl was never carried out Thus that great and memorable undertaking, after absorbing money enough to build and equip a most magnificent laboratory, was abandoned from lack of interest on the part of educational institutions rather than of means Such a failure, it must be frankly confessed, is not one to inspire confidence, but its explanation removes the apparent grounds for discouragement It was the marvellous personality of Prof Agassiz that made Penikese a possibility It was his magic influence that created that school, his commanding individuality that organized and vitalized it All interests centred in him so completely that with his sudden removal the enterprise was left without a soul The school had no coherency except in his magnetic power and intellectual strength, and the moment these elements of stability were withdrawn, collapse followed as a natural and inevitable consequence. Then, too, it should be remembered that Prof Agassiz lived just long enough to demonstrate the impracticability of maintaining such a school in such a locality, but unfortunately not long enough to convince the scientific world of its utility The school was an experiment, its master was stricken down before it could be fairly tested, and the times were not ripe for it"

The establishment of this laboratory was an event of the greatest significance because of its bearings upon the history of education Not only was Penikese the first biological station established in this country, and, indeed, in the world, but it was the beginning of the summer-school movement which has spread so generally over the country, and which, it should be noted, began with original research and finally extended to include the work of elementary instruction.

The movement met with the cordial support of naturalists everywhere, and was almost immediately followed by the establishment of Dohrn's magnificent station at Naples Soon after, in 1875, a seaside station was established at Helder by the Netherlands Zoological Society, and other smaller ventures followed in Europe.

The need of opportunities for seaside study in the United States was too generally felt by those who had come under Agassiz's influence for the project to be allowed to stop The advantages of this method of work over museum study had impressed themselves at least upon a few workers, and accordingly we find several attempts made to found new laboratories They differed in character and aims, but all agreed in being founded upon the one idea of studying marine animals in their native waters.

The most direct successor of the Penikese laboratory is the private laboratory of Prof Alexander Agassiz at Newport While this building is constructed on a much smaller scale than that at Penikese and is open only to a limited number of workers, yet it is prominent for the elegance of its appointments and its conveniences for work

The first laboratory for seaside study established in this country after the abandonment of Penikese was maintained by the Peabody Academy of Sciences, under the guidance of Prof Packard, with the co-operation of Prof Kingsley and others This laboratory was for elementary instruction rather than research, and remained in existence only from 1876 to 1881

In 1878 the trustees of the Johns Hopkins University made an appropriation to allow a party of workers to spend some time in seaside study The party was under the guidance of Dr W K Brooks, who had himself been a pupil of Agassiz and a member of the Penikese laboratory The location selected was at the lower part of the Chesapeake Bay, from which the name of Chesapeake Zoological Laboratory was chosen No permanent buildings were erected, as it was intended, if possible, to change the location from year to year, but an outfit of boats and collecting apparatus was provided The summers of 1878 and 1879 were spent about the lower part of Chesapeake Bay at Crisfield, Md, and Fort Wool, Va., at which places special attention was given to the development of the oyster

At the opening of the third season, in 1880, the need was felt of a locality that would offer a greater variety of objects for study, and accordingly the summers of 1880–82 were spent at Beaufort, N C This locality proved especially favourable, since sand bars, mud flats, salt marshes, and land-locked salt water, within easy reach, gave a large variety of different rare forms, and there was also abundant ocean dredging A sufficient appropriation was made in 1880 to purchase a steam launch and a sloop, which put the workers in a position to take every advantage of their opportunities

In 1883 a special study of oyster beds made a return to the mouth of the Chesapeake Bay necessary, and that season was spent at Hampton, Va, but the following two seasons were again spent at Beaufort

In 1886 the need of a more southern location was felt, and the Bahama Islands seemed to offer an inviting field The summer of 1886 was therefore spent at Green Turtle Cay, and the following summer at Nassau, New Providence

Financial difficulties temporarily stopped the work of the laboratory, but it is announced that it will be reopened in the summer of 1891 [1]

It is difficult to summarize the work of this laboratory, and none the less so to over estimate its importance. It enjoys the distinction of being the first marine laboratory ever carried successfully into operation in the United States, and its work was entirely original research The character of work done differed from year to year, according to the facilities which the different localities offered, but in general it may be said that embryology received most attention, while considerably less was devoted to the discovery and description of new species. The methods employed, as well as the new facilities enjoyed, made it possible to apply effective means of solution to many problems previously obscure, as well as opening many questions in regard to which nothing had been done

Of the lasting value of the work it is perhaps too early to speak, but the fact that over one hundred papers, based upon work there performed, have readily found publication in the best journals of this country and Europe, as well as the fact that much of the work has already found its way into standard text-books, gives strong testimony to its value.

The Chesapeake Zoological Laboratory may be regarded as the successor of the Penikese laboratory to the extent that its aims are the same, but it differed in not being generally open to the workers of the country. Arrangements were not made for large numbers, and those who were present were mainly students of the Johns Hopkins University. During the nine years that this laboratory remained in existence, there were in all fifty investigators present, and the average length of each session was nearly two months.

The need was felt, especially in that portion of the country where Agassiz's influence was more directly exerted, of establishing a laboratory on a larger scale, and open to a larger

[1] Shortly after the above was written, Kingston, Jamaica was chosen as a suitable locality, and a party of advanced workers, numbering about fourteen in all, were present from May until September — September 21, 1891

number of workers, and the first step taken in this direction was the founding of a laboratory by the Boston Society of Natural History. In their report for 1881 these words occur:

"It has been considered desirable to found a summer laboratory sufficient to supply the needs of a class of persons who have begun to work practically under our direction, but have hitherto had no convenient means for pursuing their studies on the seashore . . . We are sure that such a laboratory is needed for a limited number of persons, such as our own pupils in natural history, and some of the teachers of the Boston public schools, about a dozen in all, but we are not sure of any real demand outside of these."

Arrangements for laboratory work were speedily made at Annisquam, Mass. Boats and appliances for collecting were at once provided, and in the spring of 1881 a circular was issued announcing the opening of the new laboratory. From this the following extracts are taken:—

"The liberality and co-operation of the Woman's Educational Association enable the Boston Society of Natural History to announce that a seaside laboratory, under the direction of the curator (Prof. Alpheus Hyatt), and capable of accommodating a limited number of students, will be open at Annisquam, Mass., from June 5 to September 15.

"The purpose of this laboratory is to afford opportunities for the study and observation of the development, anatomy, and habits of common types of marine animals, under suitable direction and advice. There will, therefore, be no attempt during the coming summer to give any stated course of instruction or lectures.

"It is believed that such a laboratory will meet the wants of a number of students, teachers, and others who have already made a beginning in the study of natural history."

Twenty-two persons were attracted to the Annisquam laboratory during its first season. Prof. Hyatt, in his report for 1882, remarks as follows:—

"The great need of an institution for teaching field work cannot be properly estimated by the number of those who are attracted by the opening of such opportunities for study. The mental condition of those who attend, and what it has done for them, and the sphere of influence which it reaches through them, are the only true standards by which its present and future usefulness can be properly measured. Nearly all the pupils were persons who could be termed 'well educated,' nevertheless they were, with the exception of some who had already worked in the laboratory or field, entirely unable to obtain knowledge with their own eyes and hands, and had even acquired a notion that this was not possible for anybody except the trained man of science. Several of these teachers, after their work was finished, expressed their gratefulness for the new powers the course had developed in themselves, and the fascinating pleasure they had experienced in learning to use their own eyes and hands in the study of things hitherto unapproachable for their uncultivated senses except through the deceptive mediation of books. When it is remembered that these teachers influence and mould the minds of thousands of young persons it is at the same time proved that what this laboratory has done and can do is not to be estimated by the number of its own pupils."

The success of the undertaking seemed assured, and arrangements were made for its continuance during the five years following. The number of students fluctuated greatly, falling to ten in the third year, and running up in the sixth year to twenty-six.

During these six years the laboratory was carried on jointly by the Boston Society of Natural History and the Woman's Educational Association of Boston. It has been the policy of both of these associations to originate new enterprises, but to turn them over when well started into other hands. It seemed in 1887 that the time had come when the maintenance of the laboratory should be put on a firmer basis. It had been supported long enough to demonstrate its practicability and usefulness. The demands upon it had increased. It was no longer an experiment. The associations believed that a permanent organization should be effected, the working facilities increased, and the whole established on a larger scale. Moreover, it seemed that something more might be done to give the laboratory a wider sphere of usefulness in advancing knowledge of marine life. Great as was its work in teaching, it seemed to depend for its support upon a circle of people too small for the extent of its benefits. It seemed desirable that a change should come which would lead to a more widespread interest in the laboratory, and bring together more investigators. The Marine Biological Laboratory was the result of this movement.

While space will permit but a brief account of this laboratory, its history, development, aims, &c., it may be said that the one point which distinguished it from the Annisquam laboratory was the prominence given to research. Students are received, but from the outset there has been a settled determination to so adjust the claims of each as to secure the greatest amount of efficiency and do most to advance science. The organization was therefore effected so as to secure a permanent staff of investigators, who would always be present, increasing knowledge by their own work, and by their example stimulating others to follow. Moreover, the principle was thoroughly recognized that the best investigation is prompted by the work of teaching. The best investigator is often the best teacher, but the work of teaching reacts upon the work of investigation, influencing it for the better.

The experience of the laboratory shows that these points, which had previously been carefully considered, were well taken. Various means were resorted to for providing funds, and in March, 1888, the laboratory was incorporated.

Wood's Holl was chosen as a locality because of its convenience, accessibility, and the variety of its land and marine flora and fauna. The building was at once begun, and finished in time for work during the summer. Circulars could not be issued until after most of the colleges had disbanded for the summer, and yet during the first season seven investigators and eight students were attracted to the laboratory.

In subsequent years the growth has been a steady one. The number of workers has greatly increased, and even now, when only its third season has been passed, it is stated that the space is insufficient to meet the demands upon it; the facilities for collecting are too small, and the staff of instructors is not large enough for their classes. Its usefulness is now established, and the time is ripe for it. To it in great measure the United States must look for the advancement of biology. Let us hope that its trustees, all of whom are working biologists, may be successful in placing the laboratory upon such a financial basis that its full possibilities for usefulness may be realized.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge.—Dr. Hill, Master of Downing College, has been appointed Chairman of the Natural Science Tripos Examiners for 1893. An election to an Isaac Newton Studentship in Astronomy, Astronomical Physics, and Physical Optics, will be held in the Lent term 1893. Candidates must be B.A.'s, and under twenty-five years of age on January 1. The emoluments are £200 per annum for three years. Applications are to be addressed to the Vice-Chancellor between January 17 and 27, with testimonials or other evidence of competency.

Dr. Lorrain Smith, M.D. Edin., Demonstrator of Physiology at Oxford, and Dr. F. F. Wesbrook, M.D., Manitoba, Professor of Pathology at Winnipeg, have been elected John Lucas Walker Students in Pathology. The Managers express their high approval of the valuable researches conducted by the late student, Dr. A. A. Kanthack, of St. John's College. The State Medicine Syndicate state that, at the two examinations held in April and October, 1892, there were in all sixty-four candidates, of whom thirty-five received Diplomas in Public Health. The fee in future will be five guineas for each of the two parts of the examination in State Medicine.

Examinations for open scholarships and exhibitions in Natural Science will be held in twelve of the Colleges in December and January next. A list giving the conditions and value of the scholarships is published in the *University Reporter* of November 12, pp. 198, 199.

SCIENTIFIC SERIALS.

Wiedemann's Annalen der Physik und Chemie, No. 10.—Refraction and dispersion of light in metal prisms, by D. Shea. Thin prisms of gold, silver, nickel, and cobalt were prepared by the electrolysis of cyanide solutions by Kundt's method. Prisms of platinum were also prepared by the disintegration of platinum foil. A piece of foil 4 mm. broad and 0·02 mm. thick placed perpendicularly to a piece of plate glass at a distance of 0·5 mm. produced under the action of a current of 20 amperes a double wedge-shaped layer of oxide in half an hour.

This was easily reduced by a Bunsen flame, so as to represent a metallic prism with an angle of some 20 seconds. Only one in twenty of the prisms could be used, and only one in 200 silver or gold prisms. The source of light was a zirconium burner with a red shade transmitting light of the mean wave-length $64 \times 10^{-}$ cm. The index of refraction was found to vary with the incidence. For perpendicular incidence the following values were found: Au 0·26, Ag 0·35, Cu 0·48, Pt 1·99, Ni 2·01, Iron 3·02, Co 3·16. For silver the index was 0·39 at an incidence of 10°, 0·60 at 30°, 0·80 at 50°, 1·01 at 80°, and 1·03 at 90°. The following refractive indices for various wave-lengths illustrate the dispersion:

	Li, α	D	F	G
Au	0·29	0·66	0·82	0·93
Ag	0·25	0·27	0·20	0·27
Cu	0·35	0·60	1·12	1·13
Pt	2·02	1·76	1·63	1·41

—On a law of refraction for the entrance of light into absorptive media, by H. E. J. G. du Bois and H. Rubens.—On the infra-red emission spectra of the alkalies, by Benjamin W. Snow.—Absolute change of phase in light by reflection, by Paul Glan.—Inductive representation of the theory of double refraction, by Franz Koláček.—Studies in the electric theory of light, by D. A. Goldhammer.—On the passage of feeble currents through electrolyte cells, by Rud. Lohnstein.—On the motion of the lines of force in the electro-magnetic field, by Willy Wien.—On the electric theory of magneto optic phenomena, by D. A. Goldhammer.—An automatic interruptor for accumulators, by H. Ebert. This is to prevent the current from the accumulator exceeding the supply for which it is constructed. Two mercury cups are inserted in the circuit, connected by a piece of stout copper wire. The current next passes through an electro magnet. As soon as the current reaches a certain strength the electro magnet overpowers an adjustable spring, and lifts the copper connecting-piece out of the cups.—Contribution to the history of the spheroidal phenomena, by G. Berthold.

SOCIETIES AND ACADEMIES

LONDON

Physical Society, October 28.—Dr. J. H. Gladstone, F.R.S., past president, in the chair.—The discussion on Mr. Williams's paper, "On the relation of the Dimensions of Physical Quantities to Directions in Space," was opened by Prof. Perry reading a communication from Prof. Fitzgerald, president. The writer said Mr. Williams disagreed with the suggestion that electric and magnetic inductive capacity are quantities of the same kind principally because he had not got over the curious prejudice that potential and kinetic energy are different. No theory of the ether could be complete unless it reduced its energy to the kinetic form. Electric and magnetic inductive capacity would probably be found to be similar in the ether, and ultimately have the same dimensions. The analogies were not yet complete, but only in respect of *matter* was it probable that any difference existed between them. Diamagnetism corresponded to electrostatic induction, but paramagnetism had no definite electrical analogue. He was inclined to regard the phenomena of paramagnetism as connected with the arrangement of the material molecules, whilst diamagnetism depended on the electric charges on those molecules. So far no matter had been found which conducts magnetism, and such may not exist in our universe, but it may be gravitationally repelled by matter as we know it.—Mr. Madan remarked that in the first part of his paper Mr. Williams recognized that dimensional formulæ were originally change-ratios, but puts this aside for the higher conception which regards these formulæ as expressing the nature of the quantity. Fourier showed how to find the dimensions of units by making the size of the fundamental units vary. But k (specific inductive capacity) did not vary with the fundamental units, for it was merely the ratio of the capacities of two condensers, and therefore, by Mr. Williams's definition, a pure number. It was difficult, he said, to see how k could have dimensions, but Mr. Williams regarded it as a physical quantity, and therefore possessing dimensions. The object in giving dimensions to k and μ seemed to be to get over the double system of units. Mr. Madan did not think that dimensions could express the nature of physical quantities, and said differences of opinion existed amongst authorities on this point. For example, Dr. J. Hopkinson, at the last B.A. meeting, said that because a co-efficient of self-induction had the dimensions of length it must be a length, whilst other learned professors objected to this view. Even if one admitted that dimensions are a test of the nature of physical quantities it was not necessary that the two systems of units should be identical. The connecting link between the two systems was $Q = C\,t$, and the validity of this equation had been questioned. If this objection be confirmed, then there would be no current in electrostatics and no Q in the electromagnetic system, and the units would not clash. Referring to dynamical units, Mr. Madan pointed out that two units of mass were used in astronomy, but astronomers got over the difficulty by using a co-efficient. Dimensional formulæ, he said, are the result of a convention that certain definitions should hold true generally, but they contain no further information respecting the nature of the quantities beyond that involved in those definitions. As an example of the inability of such formulæ to express the nature of quantities, he pointed out that whilst physical differences were known to exist between + and − electricity the dimensional formulæ showed no signs of such differences.—Prof. Rucker said every correct physical equation consisted of a numerical relation between physical quantities of the same kind, and might be written either as a mere numerical equation or as a relation between the physical quantities themselves. The equation $2 + 1 = 3$ may correspond to 2 feet + 1 foot = 3 feet, and the latter may be written 2[L] + 1[L] = 3[L], where [L] represents the unit of length. So far as he was aware, nobody but a recent writer in the *Electrician* had denied that in such an equation [L] represented a concrete quantity. Maxwell explicitly stated that it does in his article on "Dimensions" ("Encycl. Britt.") and elsewhere, and Prof. J. J. Thomson, in his paper on the same subject, makes no statement contrary to this. The above equation might also be written 2[feet] + 1[foot] = 1[yard]. Another equation involving time is 60[sec.] = 1[minute], and dividing one by the other one gets

$$\tfrac{2}{60}\left[\frac{\text{feet}}{\text{sec.}}\right] + \tfrac{1}{60}\left[\frac{\text{foot}}{\text{sec.}}\right] = 1\left[\frac{\text{yard}}{\text{min.}}\right]$$

A difficulty was felt here in understanding what dividing a foot by a second meant, but this difficulty Prof. Rucker considered was not greater than that involved in dividing an impossible by a real quantity, a very familiar analytical device. Reasons for regarding the symbols $\left[\frac{\text{foot}}{\text{sec.}}\right]$ as legitimate were then given. Prof. Henrici said the communication under discussion was one of the most important contributions to physical science which he had come across for a long time. Such difficulties as presented themselves in the paper arose from its fundamental character. The author had attempted to express all physical quantities in terms of three, but quantities may exist which cannot be completely represented in terms of L, M and T. The tendency of modern mathematics was to express everything dynamically. Mathematicians had long been in the habit of using quantities which were neither numbers nor concretes in the ordinary sense, and different kinds of algebra with units not understandable had been developed. If a quantity, a times a unit u, be multiplied by b times another unit v, the result is expressed by $ab\,uv$, where ab is a number and uv a new unit which may or may not be physically interpretable. The interpretation of a product depended on the meaning attached to "multiplication," and if this be restricted to "repeated addition" the range is very limited. The narrow conceptions concerning multiplication acquired at school could only be removed by a careful study of vectors. Mr. Williams had treated his subject by vector methods, but a few traces of quaternions remained which might be omitted. To truly understand the subject, vectors must be treated vectorially. Dimensions might then show the nature of the quantities involved. The system adopted in Mr. Williams's paper was probably the best attainable at present, but he (Prof. Henrici) looked forward to the use of a more fundamental quantity than the vector—viz. "the point"—as the ultimate basis. Grassmann had worked out a "point calculus" in 1844, which was republished in 1880. Quantities more complex than vectors, viz. rotors, screws, motors, &c., had been used with advantage by Clifford, Ball, and others. Dr. Sumpner thought the first ideas of students on the subject of dimensions were that they represented the nature of the quantities, but could not see why every quantity should be expressed in terms of L, M and T. Prof. Rücker's paper on "Suppressed Dimensions" had cleared up several important points, and he (Dr. Sumpner) now considered that every quantity

must be expressed in terms of a unit of the same kind as itself He viewed Mr. Williams's attempt to express everything in terms of L, M and T, as rather a retrograde step The discussion on Mr Williams's paper was adjourned, and Dr Young made some remarks on Mr Sutherland's communication "On the Laws of Molecular Force" Mr Sutherland, he said, thought that Ramsay and Young's law $\partial p/\partial T = f(v)$ is not correct for compounds in the liquid state. Barus, however, had proved that several liquids, including ether, only showed variations from the law at extremely high pressures After writing the equation of the virial in the form $pv = RTvf(v) + v\phi(v)$, where $v\phi(v)$ stands for the internal virial term, the author of the paper had shown that $v^2\phi(v)$ ought to be constant, but, finding it not constant in the case of ether, &c, he attempted to explain the discrepancies by the formation of pairs of molecules at small volumes Other substances, such as nitrogen and methane, were supposed to follow the law This, Dr Young said, could not be accepted as proved, for the range of volumes over which the experiments had been made was only small, and methane was difficult to prepare pure After criticizing the use of two and sometimes three "characteristic equations" for the same substance, he went on to show that the formulæ given in the paper by which the critical temperatures, pressures and volumes might be calculated, lead to results differing from experimental numbers by quantities greatly in excess of experimental errors Experiment also showed that capillarity had little or no effect on the determination of critical constants Speaking of critical volumes he pointed out that MM Cailletet and Mathias had published a method of finding critical densities which gave very accurate results Mr Sutherland's conclusions respecting Van der Waals's generalizations were practically identical with those expressed by Dr Young in his paper on the subject, read before the Society last year The views as to the nature of the various kinds of "pairing" mentioned in Mr Sutherland's paper were open to serious objections, for his "physical pairing" is supposed to produce more effect on the "characteristic equation" than true chemical pairing In his (Dr. Young's) opinion the idea of physical pairing appears somewhat speculative and requires further elucidation —A paper on the determination of the critical density, by Dr Young and Mr. A L Thomas, and two papers, on the determination of the critical volume, and on the boiling points of different liquids at equal pressures, by Dr Young, were taken as read The first paper gives an account of results obtained by Cailletet and Mathias's method, based on the fact that the means of the densities of a substance in the states of liquid and saturated vapour when plotted with temperature, lie on a straight line which passes through the critical point In the paper on critical volumes the above-mentioned method is again referred to and results obtained thereby accepted in preference to those given by the author in his paper on Generalizations of Van der Waals, &c, read before the Society about a year ago The alcohols do not strictly follow the straight-line law Revised tables of critical volumes, densities, pressures, and temperatures are given, and it is pointed out that for many substances the ratio of the actual critical density to the theoretical density (for a perfect gas) is about 3 8 The paper on boiling-points of different liquids at equal pressures contains a comparison of the accuracies with which a formula for the relation between the boiling-points given by M Colot (*Compt Rend*, cxiv p 653), and one by Ramsay and Young (*Phil Mag.*, January 1886), accord with experimental results The author concludes that the latter formula shows the best agreement, but that of M Colot is satisfactory under certain conditions. The further discussions of Mr Williams's and Mr Sutherland's papers were adjourned till the next meeting

Mineralogical Society, October 25.—At the Anniversary Meeting the following were elected Officers and Members of Council —President, Prof N S. Maskelyne, F R.S ; Vice-Presidents, Rev Prof S Haughton and Dr Hugo Müller, F R.S., Treasurer, Mr F. W Rudler, F G S., General Secretary, L. Fletcher, F R S , Foreign Secretary, Mr. T. Davies; Ordinary Members of Council, Prof. A H Church, F R.S., Prof. Grenville A. J. Cole, Mr T W. Danby, Dr C Le Neve Foster, F.R.S , the Rev. H. P. Gurney, Mr. J. Horne, Prof J W Judd, F.R.S., Prof G. D Liveing, F R.S , Lieut General C. A. McMahon, Mr. H A. Miers, Mr F. Rutley, and Mr J. J H Teall, F.R.S.—Dr C. O. Trechmann detailed the results of the goniometrical measurement of two very perfect crystals of Binnite collected by himself in the Binnenthal. The measurements, besides adding a large number of forms to those previously recorded for this species, serve to establish the tetrahedral hemisymmetry of the mineral which has been left as a very doubtful feature by previous observers, and was denied by Hessenberg —Mr H A Miers and Mr G T Prior announced the results of further researches on the rare silver minerals known as Xanthoconite and Rittingerite According to their physical measurements and chemical analyses these two substances are identical, both having the same composition as Proustite, and crystallizing in rhombic shaped tables belonging to the mono-symmetric system The name Xanthoconite, given by Breithaupt, has the priority; the red silver ores are now to be regarded as an isodimorphous (?) group consisting of the two sulph arsenites Proustite and Xanthoconite, and the two sulph-antimonites Pyrargyrite and Fire-blende Previous determinations of the composition of Rittingerite and the crystalline form of Xanthoconite have been erroneous —Mr Fletcher gave a description of a new habit of Descloizite from the Argentine, and also an account of the new mineral Baddeleyite (native zirconia) the only fragment as yet found is part of a twinned crystal showing forms which belong to the mono-symmetric system pleochroic optically negative and biaxal with inclined dispersion specific gravity 6·025 hardness 6 5 —Mr Allan Dick contributed further remarks on Geikielite, supplementing his paper read at the previous meeting —Prof Judd exhibited photographs in illustration of his previous paper on the lamellar structure of quartz crystals and the method by which it is developed.—Mr Rutley exhibited a large series of beautiful cardboard models illustrative of the symmetry and optical characters of the crystalline systems — Mr Miers exhibited specimens, including the rare mineral Turnerite from the Tintagel Slate quarries which he had visited in search of that mineral

Zoological Society, November 1—Sir W H. Flower, F.R S , President, in the chair —The Secretary read a report on the additions that had been made to the Society's Menagerie during the months of June, July, August, and September, 1892, and called special attention to a young Gibbon from Hainan, South China, of a uniform black colour, belonging to the species recently described by Mr Oldfield Thomas as *Hylobates hainanus*, presented by Mr Julius Neumann, and to a young male Malayan Tapir (*Tapirus indicus*) from Tavoy, Burmah, presented by Col. F M Jenkins —Mr E Hartert exhibited (on behalf of the Hon Walter Rothschild) examples of two new Mammals from New Guinea (*Proechidna nigro aculeata* and *Acrobates pulchellus*), and a stuffed specimen of *Apteryx maxima* from Stewart Island —A communication was read from Lord Lilford, giving an account of the breeding of a pair of Demidoff's Galagos in his possession —Prof Bell read a note on the occurrence of *Bipalium kewense* in Ireland — Mr Finn gave an account of his recent zoological excursion to Zanzibar —Prof. Newton, F R S , exhibited and made remarks on a specimen of *Sylvia nisoria* lately killed in England —Prof F Jeffrey Bell read a description of a remarkable new species of Echinoderm of the genus *Cidaris* from Mauritius, proposed to be called *C curvatispinis* —A communication was read from Sir Edward Newton, and Dr Gadow, F.R S., describing a collection of bones of the Dodo, and other extinct birds of Mauritius, which, having been recovered from the Mare aux Songes in that island by the exertions of Mr Theodore Sauzier, had been by him entrusted to them for determination. The collection contained examples of the atlas, metacarpals, pre-pelvic vertebra, and complete pubic bones of the Dodo, which had before been wanting, as well as additional remains of *Lophopsittacus*, *Aphanapteryx*, and other forms already known to have inhabited Mauritius. Besides these there were bones of other birds, the existence of which had not been suspected, and among them of the following, now described as new — *Strix* (?) *sauzieri*, *Astur alphonsi*, *Butorides mauritianus*, *Plotus nanus*, *Sarcidiornis mauritianus* and *Anas theodori*, the whole adding materially to the knowledge of the original fauna of Mauritius —Mr. Oldfield Thomas gave an account of a collection of Mammals from Nyassa-land, transmitted by Mr H H Johnston, under whose directions they had been obtained by Mr Alexander Whyte.—Dr Günther, F.R.S., read a paper descriptive of a collection of reptiles and Batrachians from Nyassa-land, likewise transmitted by Mr. Johnston, and containing examples of several remarkable new species, amongst which were three new Chameleons, proposed to be called

Chamæleon isabellinus, *Rhampholeon platyceps*, and *R. brachyurus*.—Mr. R. Lydekker read a memoir on some Zeuglodont, and other Cetacean remains from the Tertiaries of the Caucasus.—Mr. Martin Jacoby read the descriptions of some new genera and new species of Phytophagous Coleoptera from Madagascar.

Linnean Society, November 3.—Prof. Stewart, President, in the chair.—The Rev. Prof. Henslow exhibited an instrument used in Egypt for removing the end of the sycamore fig, and gave some account of the mode of cultivation.—Mr. A. Smith Woodward exhibited and made remarks on some supposed fossil lampreys (*Palæospondylus gunni*) from the old red sandstone of Caithness.—The Rev. E. S. Marshall exhibited some hybrid willows from Central Scotland, believed to be rare or new to Britain.—Mr. G. N. Douglass exhibited the train of a peahen which had assumed the male plumage. The bird, which was reared at the Castle Farm, Tilquhillie, near Banchory, N.B., was believed to be about thirty years old at the time of its death, and for some years previously had not laid any eggs. In the opinion of the exhibitor and others present the phenomenon was correlated with disease of the ovaries. Similar cases had occurred with fowls, pheasants, and black game, but not, so far as was known, with peafowl.—Mr. C. T. Druery exhibited some new examples of apospory in ferns, namely a specimen of *Athyrium filix fœmina var. clarissima* with pinnæ showing development of prothalli by soral apospory, and a seedling *Lastrea pseudomas cristata*, showing prothalli developed aposporously over general surface of frond (pan-apospory).—Mr. J. E. Harting exhibited some live specimens of the short tailed fieldvole (*Arvicola agrestis*), and gave an account, from personal inspection of the serious damage done by this little rodent upon the sheep-pastures in the lowlands of Scotland.—Mr. A. B. Rendle exhibited some seedling plants of the sugar cane which had been raised in this country by Mr. Veitch.—The discussion on several of these exhibitions having continued until a late hour, a paper by Prof. Henslow, on a theoretical origin of endogens through an aquatic habit, was by consent adjourned to the next meeting of the Society, which will be held to-day.

Mathematical Society, November 10.—Prof. Greenhill, F.R.S., President, in the chair.—This was the annual general meeting and after the election of the gentlemen whose names are given on p. 616 (NATURE, vol. xlvi.) to serve on the council for the session 1892–93, the new President, Mr. A. B. Kempe, F.R.S., took the chair and at once called upon the retiring president to read his valedictory address. Prof. Greenhill took as his subject collaboration in mathematics.—The following further communications were made: Some properties of homogeneous isobaric functions, by E. B. Elliott, F.R.S. This paper is a sequel to one which the writer communicated at the June meeting entitled a proof of the exactness of Cayley's number of seminvariants of a given type. The earlier part of the present paper supplies omissions in the preceding one and in the remainder the theorem on which Mr. Elliott's argument was based is transformed, and the result examined for its own sake without reference to the particular application.—On certain general limitations affecting hyper-magic squares, by S. Roberts, F.R.S. The paper does not aim at making any addition to the known ways of constructing magic squares. Hyper-magic squares, as the writer regards them, include those called by M. E. Lucas "carrées diaboliques," and also treated by Mr. A. H. Frost under the designation of "Nasik squares." The special form is of ancient origin. The second method given by Moschopulus (thirteenth century) is a general one for forming such squares and they have been discussed by various modern authors. The writer's object is to show some limitations to which they are subject when the elements are positive or negative integers. Incidentally it appears that hyper-magic squares of oddly even orders cannot be formed of series of consecutive natural numbers. There is some reason for believing that much ingenuity has been fruitlessly employed in trying to form such squares. We may here mention that a very interesting historical essay on the subject of magic squares has been published by Dr. Siegemund Günther, in his work entitled "Vermischte Untersuchungen zur Geschichte der Mathematischen Wissenschaften" (Leipsic 1876). The subject has also been brought into connection with the "Geometry of Tissues," by M. Lucas and others (see the "Principii Fundamentali della Geometria dei Tessuti," par Edoardo Lucas, Torino, 1880).—Note on the equation $y^2 = x(x^4 - 1)$ by Prof. W. Burnside.—Note on secondary Tucker circles by Mr. J. Griffiths. The idea of this note sprang from the fact that if G, g, are two inverse points with respect to the circumcircle (ABC) whose centre is O, i.e. such that $OG \times Og = R^2$, then the pedal triangles DEF, *def* of G, g, with regard to ABC are similar. Taking G to be one of the Brocard points, then (DEF) is a Tucker circle and (*def*) a secondary circle.—On a group of triangles inscribed in a given triangle ABC whose sides are parallel to connectors of any point P with A, B, C, by Mr. Tucker. If DEF, D'E'F', are a pair of such triangles they are readily seen to be in perspective. Their properties are considered with reference to the principal points and lines of the modern geometry of the triangle.—A note on triangular numbers by Mr. R. W. D. Christie.

PARIS

Academy of Sciences, November 7.—M. de Lacaze Duthiers in the chair.—Letter addressed to the President by the committee formed to celebrate the seventieth birthday of M. Pasteur.—Influence of the distribution of manures in the soil upon their utilization, by M. H. Schlœsing.—Note on the reply of M. Berthelot to my note of October 24, by M. Th. Schlœsing.—Comparison of the magnetic observations of General Pevzoff in Central Asia with the data of the English magnetic charts, by M. Alexis de Tillo. General Michael Pevzoff, in his last exploring tour in Eastern Turkestan, made some careful determinations of magnetic declinations and inclinations. If these are compared with those published by M. Creack in the report of the *Challenger* expedition, it appears that in declination an average correction of + 1°.7 has to be applied to the latter, while the inclinations are practically identical.—On the new triangulation of France, by M. L. Bassot. This work was commenced in 1870. It comprised the establishment of a continuous chain between the Spanish frontier and Dunkerque, supporting the net on three base lines, and attaching it as far as possible to each of the parallel chains of the old triangulation. Also a new determination of the co-ordinates of the Panthéon, the fundamental point of the triangulation, the measurements of base lines in terms of the international metrical standard, and the calculation of the new arc of meridian. It was found that, starting from the Paris base-line, the network was verified at Perpignan, at a distance of 6°, to within 1 in 250,000. Where the French system meets the English, Belgian, and Italian systems, the correspondence is found practically perfect, but on the Spanish frontier there exists a difference of 1 in 65,000 at present unexplained. The arc between Dunkerque and Carcassonne, as now calculated, exceeds that of Delambre by 44.7m., or 1 in 20,000.—Essay on a general method of chemical synthesis, by M. Raoul Pictet.—On the fifth satellite of Jupiter, by M. E. Roger. From the empirical formula for the distances of Jupiter's satellites

$$\log \text{hyp}\, a = 8 - \frac{3m}{2\pi} - 0.03 \cos \frac{m\pi}{5} + \epsilon$$

the probable distances of any satellites yet undiscovered can be calculated. It appears that there may be one at distance 1.97, two others at 1.61 and 1.27, or a single one at 1.425, and others beyond the outermost satellite. The distances of those already known are 2.50, 6.05, 9.62, 15.35, and 27.00.—On the transformations of dynamical equations, by M. Paul Painlevé.—Lenticular liquid microglobules and their conditions of equilibrium, by M. C. Maltézos. The smallest drops of a liquid jet falling upon another liquid often assume a lenticular shape, one surface of which is more curved than the other. These are called microglobules. Their diameters were measured, and their volumes and masses calculated. The production of microglobules in all the liquids in Quincke's table was experimented upon.—Effects of weight on fluids at the critical point, by M. Gouy.—Dilatation of iron in a magnetic field, by M. Berget. An elegant experiment to exhibit the lengthening of an iron bar on magnetization, on the principle of Newton's rings. The bar in question, provided with a cap of black glass, presses against the flat side of a plano-convex lens screwed to the same stand. The bar is surrounded by a coil, which can be excited by a battery of accumulators. Magnetization is at once indicated by the expansion of the rings.—On the dissipation of the electric energy of the Hertz resonator, by M. V. Bjerknes (see *Wiedemann's Annalen*, No. 9).—On the equality of potential at the contact of two electrolytic deposits of the same metal, by M. G. Gouré de Villemontée.—On the rotating power of the diamine salts, by M. Albert Colson.—Volumetric determination of the alkaloids, by M. E. Léger.—On the fixation of free nitrogen by

plants, by MM Th Schlœsing, jun, and Em Laurent — Observations on the preceding note, by M. Duclaux — Observations on the preceding communications, by M Berthelot — On γ-achroglobine, a new respiratory globuline, by M A B Griffiths — On the axinite of the Pyrenees, its forms and its conditions of occurrence, by M A Lacroix — On the subterranean river of the Tindoul de la Vayssière and the springs of Salles la-Source (Aveyron), by MM E A Martel and G Gaupillat — On the comparative anatomy of the stomach in Ruminants, by M J A Cordier — Remarks on some means of defence in the æolidians, by M E Hecht. — On the evolution of the brachial apparatus of some brachiopods, by MM P Fischer and D P Œhlert — On the mechanism of solution of starch in plants, by M A Prunet — On the diuretic and ureopoietic action of the alkaloids of cod liver oil on man, by M J Bouillot — Results obtained at the crystal works of Baccarat by the introduction of metastannic acid into putty powder, by M L Guéroult

BERLIN

Physiological Society, October 14. — Prof Munk, president, in the chair — Prof Kossel gave an account of further researches on nucleinic acid, a compound which, in union with albumin, composes the proteids of the cell-substance In earlier researches he had studied the acid as derived from yeast cells and salmon-milt, and found that while the substances obtained from these two sources differed in many respects, they resembled each other in that the ratio of phosphorus to nitrogen was in both as 1 to 3, and that they both yielded nuclein-bases during their decomposition More recent researches on the nuclein derived from the leucocytes of the thymus gland have shown that the nucleinic acid it yields is more like that from milt, and resembles the product obtained from yeast even less than does the product from milt The relationships of nucleinic acid to the chromatin bodies of the histologists were minutely considered — Prof. Gad brought forward a theory of the excitatory process in muscles, based upon the theory of Fick, but further developed and supported by experiments on tetanized muscles.

ANIMALS' RIGHTS

Animals' Rights By H. S Salt. (London Bell, 1892)

THIS little volume is divided into three main parts, the principle upon which the rights of animals are founded, the various ways in which they have been infringed, and the reforms necessary to secure their full recognition Notwithstanding, however, the logical form in which the subject is thus set forth, the book is absolutely useless both from the ethical and the practical points of view In the first place the author nowhere attempts to define the relative value of the lower animals as compared with the human race, and although he certainly allows that they possess less "distinctive individuality," he condemns the use of the terms by which they are commonly designated (such as dumb beast, live stock, or even animal), on account of the imputation of inferiority which is involved in them

He seems to be totally unaware that not only is the natural affection of animals far less enduring, and their intellect immeasurably weaker, but that of morality, *i e* the doing of right for right's sake alone, unswayed by personal feeling or the influence of others, they have absolutely no conception whatever

Ignoring, however, these fundamental distinctions from which the subjection of animals inevitably follows, Mr Salt at once proceeds to enunciate his theory of their rights.

This whole question, however, is thrown into absolute chaos by the fact that, for subsequent dealing with the practical aspects of his subject, the author has equipped himself with not merely one but two definitions of animals' rights, differing from each other so widely that while the one involves the unconditional prohibition to kill, eat, or use any harmless animal, the other would admit of all these things being done for good cause shown. Thus on page 9 we find that they have the right to live their own lives with a due measure of that restricted freedom of which Herbert Spencer speaks, *i e* the freedom to do that which they will, provided they infringe not the equal liberty of any other. Except, therefore, in the case of the beasts of prey, who no doubt would "will" to eat man if a convenient opportunity offered, the liberty to sacrifice the lives of animals for human food or indeed to employ them in any way is cut off without reserve Turn, however, to page 28 and we find that this freedom of animals is no longer restricted merely by the equal freedom of others, but is also "subject to the limitations imposed by the permanent needs and interests of the whole community" A life of idleness and a death from disease or old age and starvation are no longer secured to them, and the whole principle of the subordination of the interests of the lower race to those of the higher is conceded

From the confusion of mind thus exhibited suggestions of practical value can scarcely be expected, nor indeed do we find them in the succeeding parts of the work Thus we are told that "the contention that man is not morally justified in imposing any sort of subjection on the lower animals" is one which the author "desires to keep clear of," and pronounces to be "an abstract question beyond the scope of the present enquiry," yet, as he also states "that no human being is justified in considering any animal as a meaningless automaton to be worked, tortured, or eaten for the mere object of satisfying the wants or whims of mankind," we would submit that he has not kept clear of the matter at all, as we cannot call to mind any forms of subjection which are not included in these three

In his discussion of the treatment of domestic animals we would only draw attention to that passage wherein the degrading practice of pampering lap-dogs is rebuked as unworthy of their moral dignity ! In the succeeding chapters the employment of animals in personal decoration, sport, and scientific experiment is dilated upon and condemned, and it then only remains to consider the question of the reforms which ought to be instituted

The first remedy proposed is that of education We are all to be taught to be humane, but seeing that this has been, for countless generations, carried into effect by almost every mother with almost every child, the suggestion can hardly be accounted novel nor need any great changes in the present condition of affairs be expected from it Further, there must be a crusade preached against the disregard of the kinship of animals to ourselves, and the laugh must be turned from the so-called sentimentalists (*i e* those agreeing with the author's views) against certain flesh eaters, sportsmen, and scientific experimentalists whom he seems to have in his mind's eye, and who, seeing that he represents them as advancing absolutely foolish reasons for practices which they could easily defend on common-sense grounds, are very properly described by him as "cranks"

The second reform is to be found in legislation, and it might naturally be supposed that this should first be applied in that case which Mr Salt considers to be productive of the greatest bulk of suffering, namely in that of flesh eating But this is not so, he has already said that it is no part of his present purpose to advocate vegetarianism, and he discreetly leaves it to look after itself Then after suggesting that the worrying of tame animals might be classed as baiting, and that improvements (though what and how he does not say) might be made in the transport of animals, and by substituting public for private slaughter-houses, he demands that the full fury of the law should be turned on to scientific experiment, which must be totally abolished

The demand thus made he bases on two grounds — (1) That nothing is necessary which is abhorrent to the general conscience of humanity, and (2) That it involves hideous injustice to innocent animals, quoting with approval Miss Cobbe's, in this case, specious axiom, that the minimum of all possible rights is to be spared the worst of all possible wrongs

How far either of these arguments is applicable here we propose to briefly touch upon.

In the first place no proof whatever exists that scientific experiment *is* abhorrent to the general conscience, seeing that England is the only country where it is even under legislative supervision, that there, after the most careful deliberation, it is freely allowed on good cause shown, and that the whole body of those qualified to

judge strongly advocate it Supported, therefore, as we have shown it to be, by the legal and moral sanction of the civilized and scientific world, it follows that the "general conscience" of which Mr Salt speaks must find its local habitation in the minds of a class of persons about as enlightened as those who fomented the riots against the study of anatomy, a noisy and violent agitation, which has died the natural death of ignorant prejudice

For the refutation of the second proposition, viz that of the cruel *wrong* done to an innocent animal by sacrificing it for the good of others, we must refer Mr Salt to his own principle of animals' rights, in which the freedom conceded to them to live their own lives is very properly made "subject to the limitations imposed by the permanent needs and interests of the community," and we fail to see how the logical application of an acknowledged right can be supposed to involve the infliction of a "cruel wrong"

The contention of the scientific experimentalist is exactly that which is here conceded by Mr Salt, viz that the interests of individuals of the lower race must morally be treated as subordinate to those of the higher, and that while men are bound to benevolently regard all harmless animals, and never to inflict pain upon them wantonly, they not only may but ought to do so when the suffering thus caused is but one-tenth in intensity and one-millionth in quantity of that which it is designed to avert from both mankind and the lower animals The whole matter is in truth a rule of three sum, and unless the anti-vivisectionist can successfully demonstrate that the scientific statement of accounts is false, his outcry is but the confession of the immoral fact that, rather than inflict an infinitely less amount of physical suffering upon some individuals of a lower race, he wilfully prefers to perpetuate a far greater amount of both physical and psychical agony among the whole community of animals and men When such an avowal of callousness can be seriously advanced in the name of humanity we are tempted to believe that chaos is come again

We should not omit to mention that Mr Salt appears to be an ardent republican, and that he looks for the advent of his animal millenniun upon the establishment of an "enlightened sense of equality," but whether of men with animals, of both with insects, or all three with bacteria, he does not say, nor are we concerned to enquire

ELEMENTARY PHYSIOGRAPHY

A Description of the Laws and Wonders of Nature By Richard A. Gregory, F.R A S. (London. Jos. Hughes and Co)

NOTWITHSTANDING the numerous text-books that have been issued from time to time on this subject, it seems to Mr. Gregory that there is still room for another, for whose appearance, however, he apologizes and offers an explanation.

A work on physiography is not, as some people, who ought to know better, seem to think, limited to the study of physical geography. At least that is not the view, the author emphatically asserts, of Profs. Judd and Lockyer, whose opinion in this matter is final for the students interested Neither is it a work on astronomy, nor chemistry, nor geology, nor any specialized science, whose aim and scope are recognized and defined, though doubtless it is allied to all As soon as an author treats of any of these subjects in detail, he is travelling beyond the record To this fact Mr Gregory is fully alive His object, if we have understood him correctly, consists rather in showing that some knowledge of all branches of physical science is necessary for the pursuit of one, and this kind of general knowledge he considers comprised under the generic term, physiography It is the kind of information which every so-called educated person ought to possess, and without which he is not educated

It may not seem a very ambitious task to write a book to meet the requirements of a syllabus, and our author thinks it necessary to defend himself against the charge of producing a cram book, addressed to the few ambitious of possessing a South Kensington certificate But the task need not be the less useful or the less necessary on that account Indeed, there is one circumstance connected with the appearance of this book which is very satisfactory, and should be a subject for congratulation. The author asserts that the book is rendered essential from the fact that the examiners have found it necessary or desirable to raise their standard for examination This means that the Department has proved, that the general character of the education given to those classes from which the candidates for examination are drawn has so improved that a greater amount of information can be demanded than was formerly the case

But independently of the fact that the author addresses himself principally to those preparing for the ordeal of examination, he has produced a very readable book, a little too much like an encyclopædia perhaps for ordinary tastes, but replete with a vast deal of information, by no means ill-arranged and generally expressed with exactness, but the effort to impart and to treat lightly and discursively of many branches of information is apt to give to the book a disconnected and incoherent aspect, and this is the principal defect that can be urged against the work As soon as a subject is introduced it is necessary to drop it, because to pursue it in detail would be to enter into the domain of some science whose limits are fixed, and to which further discussion properly belongs—for instance, we have a chapter on water (its composition and different states), which it might seem very desirable to pursue at greater length, but as soon as the student gets interested, without a word of warning the subject is dropped, and he finds himself introduced to the method of measuring angular space and time. This naturally leads on to some preliminary account of astronomy and astronomical methods, ending with the measurement of the day and year, and then, on turning the page, the reader is not allowed to continue the subject, but is invited to consider the composition and characteristics of common rocks This incoherency is perhaps inseparable from the subject; but we think the author might have developed his introductory chapter at greater length and put his scheme and sequence of thought more fully before his reader, so as to prepare him for these sudden deviations from continuity.

It is instructive to notice that as educational treatises are improved in character and prepared by those qualified for the task, the reverent superstition which has for ages surrounded certain errors and fallacies, that have done duty for scientific reasoning, is being remorselessly swept away The so called proof of the sphericity of the earth, based upon the fact that ships have sailed round it, is not quoted now, even by incompetent teachers, with the same satisfactory conviction that was formerly accorded to it Mr Gregory gives a diagram which ought to convince the most antiquated schoolmistress, but such myths die hard Similarly with our friend "the burning mountain," which has frequently been regarded as an adequate definition of a volcano—that too is meeting with its deserts, but this will take a still longer time to kill, let Prof Judd and others insist as they will Many instances will occur to every one who has compared the carefully compiled text-books of to-day with those that were popular only a few years back, and no fact marks more emphatically the improvement, or the necessity for improvement, in educational treatises Definitions, to be accurate and adequate, will always be a source of trouble to the writers of elementary books, and the author of the present work has no doubt been exercised to combine the necessary accuracy and simplicity We cannot think that he has always been happy, but where so much is admirable it would be ungrateful to dwell upon small blemishes, and can only be permitted with the view of securing their improvement or removal in a future edition

The definition of meridian as given on page 105 and again at page 151 is susceptible of improvement, and it is certainly incorrect to describe a sidereal day as the interval of time that elapses between two successive transits of the same star Such little slips must be due to the hurry of production, as that on page 382, where we are told to determine the position of the north point by observing the "shadow of the sun" We should have thought the shadow of the object would have been more convenient And again, on page 407, what is meant by the sun's "regular diameter"? But such little slips as these do not materially detract from the merit of the book, which we heartily commend to the thoughtful study of those for whom it has been written

---

SCIENCE AND BREWING

A Handy Book for Brewers By Herbert Edwards Wright, M A (London. Crosby Lockwood and Son, 1892)

THE author claims that the principal aim of this book is to give the conclusions of modern research in so far as they bear upon the practice of brewing. We gathered a different opinion on first opening the volume, for facing the title-page there stands conspicuously a trade advertisement of a firm manufacturing a patented article used by brewers, stating that this article is "referred to in the work," and "for further particulars see advertisement at end of book" To any one at all familiar with the way in which quasi-scientific articles are so frequently to be met with in the literature of brewing written for the purpose of advertizing their author or some other thing, it would be only natural to conclude that the advertisement quoted was the real clue to the origin of this volume, and wonder at the unusual clumsiness with which it was made so evident However, we afterwards meet with the following statement in the author's preface "Having found after the sheets had been finally passed to the printer, that the publishers considered it would be a useful feature in the book to insert a few advertisements of matters interesting to brewers, he wishes it to be clearly understood that he has no personal interest in the matter" A little prejudice perhaps remained in our mind even after reading this disclaimer, but in justice to the author we may say at once that a perusal of the book has removed it We sympathize with him in having a publisher whose disinterested over-zeal for the convenience of his readers has given his book such an unpleasant first impression

From a scientific point of view, in one respect the practice of brewing compares with the practice of medicine, in that the complexity of vital processes has to be encountered in both, and through our present imperfect state of knowledge of these questions, the practice of both is based very largely on empiricism Fortunately for the brewer, the life functions with which he has to deal so largely belong to the more simple forms of life, and the vast strides which have been made the last few years in our knowledge of the microphytes, and the physiological processes of the higher plants, have probably placed him much nearer to a sound scientific basis on which to rest his practice, than is the physician who has to deal with the vital functions of the most highly developed organism But even yet empiricism rules many details of the brewer's practice, although research is gradually throwing true light upon them, therefore any writer who, in the present state of things, attempts to bring scientific knowledge and the practice of brewing together, has a very hard task before him in order to clearly make his readers understand the relative position in which the two stand at present Mr Wright has with much diligence gathered together the results of a large amount of research work bearing upon the different stages of the brewing process, but we do not think that he has been always happy in selecting only the most trustworthy of these, neither are we pleased with the way in which he sets them before his readers to explain, or at any rate throw light upon, the different stages of the manufacturing process It is a very difficult task, as we have just intimated, and we believe that the author, who is evidently a scientific man as well as a practical brewer, could have improved upon these parts of his work; at any rate we are quite sure that with due consideration he could easily have improved upon the general arrangement of his subjects, which is badly considered, and must be very confusing to a student not well acquainted with his subject

We also regret that space is wasted in devoting a chapter to an attempt to teach the science of chemistry to the reader Some such mistaken attempt is frequently made in technical works treated scientifically, but a greater waste of paper can hardly be imagined For instance, in the present case we have a chapter starting with a description of the elements and the atomic theory, which positively, in less than thirty-five pages, professes to lead the reader up to the consideration of the con-

stitution of the carbo-hydrates and the amido-compounds What can be the use of this sort of writing, however well done? No student not already well grounded in science generally can hope to get any real advantage from those parts of this book that are devoted to the scientific consideration of the details of the brewing process, and we wish the author had boldly recognized this very evident fact

Apart, in a manner, from the more scientific portions of his book, the author gives us his views on the empirical questions of brewing, and also on the arrangement of a brewery and its plant, with the authority of much experience Here is common ground on which all interested in brewing meet, and we recommend the author's conclusions as worth their attention At the end of the volume we find a novel feature in a synoptic table of the malting and brewing processes, giving side by side the time, working memoranda, physical changes, and chemical changes of each process, an epitome which is likely to be useful to many readers A good index also adds value to the book

Although we do not think that the author in writing this book has been very successful in meeting the requirements of young students of brewing, yet there is a large amount of information contained in the 516 pages of the volume which will repay a careful perusal by those more advanced in the study of the scientific aspect and practice of brewing

OUR BOOK SHELF

A Manual of Veterinary Physiology By Vety-Captain F Smith, M R C V S (London Baillière, Tindall, and Cox, 1892)

THE publication of this work ought to delight the heart of the veterinary student, for hitherto in his pursuit of physiological knowledge he has been compelled to rely upon works which deal exclusively with the human subject However excellent such works may be and well adapted to the requirements of the human physiologist, they must necessarily contain much which is only of secondary importance to the veterinary student, and absolutely nothing concerning many questions which to him are of vital interest For example, how needful to him is a thorough knowledge of the physiology of the horse's foot—the seat, as he is afterwards to learn, of manifold diseases Yet clearly the consideration of this subject is outside the range of human physiology Similarly the composition, digestibility, and feeding properties of the foods supplied to the various domestic animals are to him matters of paramount importance Yet here again he finds himself left in the lurch by the standard works on human physiology Such considerations amply indicate the necessity for a work of the kind now before us, and cause us to wonder that the veterinary profession should have had to wait so long for its publication Though several first rate treatises on veterinary physiology exist in French and German literature, Captain Smith's is the first attempt, we believe, to deal with the subject in its entirety in this country

We can heartily congratulate the author on the manner in which he has performed his task He writes in a concise but precise style Bearing in mind how many subjects the student is supposed to take up and master in a comparatively short time, the author has omitted, and we think wisely so, the details of physiological experimental methods and descriptions of elaborate mechanical appliances employed in the laboratory

The value or usefulness of the horse depends so largely upon its powers of speed or draught that a knowledge of its locomotory apparatus is obviously imperative to the veterinarians During recent years much light has been thrown upon the subject of animal locomotion by the elaborately devised experiments of Stillman and Muybridge, carried out, as is well known, by means of instantaneous photography Captain Smith furnishes a capital *résumé* of the conclusions derived from these experiments and a number of plain, simple diagrams aid the reader considerably in comprehending the subject

The physiology of the horse's foot is dealt with in a somewhat short chapter The author adheres to the theory of the expansion of the foot at its posterior part when the weight of the body is imposed thereon It is a subject which has often been hotly debated, and its discussion will probably be again reopened in the columns of the veterinary periodicals. The chapter concludes with some half-dozen rules on physiological shoeing, a copy of which might well be suspended and acted upon in every place where the shoeing of the horse is carried on

The book is well printed, neatly bound, and published at a very reasonable price (10s 6d.) Horse-owners as well as veterinarians will find its perusal attended with profit as well as interest W F G

The Principal Starches used as Food By W Griffiths (Cirencester Baily and Son, 1892)

THIS little book of 62 pages will be found useful by analysts and others who are interested in the examination of foods The author has collected together short descriptions dealing with the origin and microscopical characters of the different starches met with in commerce—the arrowroots, tapioca, sago, the starches of our common cereals, and of millet, maize, rice, the bean, the pea, the lentil, the potato, and so forth These are classified according to the natural orders of the plants from which they are derived, and the descriptions are accompanied by remarkably good photo micrographs, which indicate at a glance the peculiarities of the different varieties The mode of classification serves to bring out the resemblances which often exist in starches obtained from plants of the same natural order Since the microscope alone can be employed in attempting to trace the origin of a starch, and bearing in mind the extent to which it is now used as an adulterant, this handy little book will no doubt supply a want

Three clerical errors were noted On p 47 "feint" should be "faint," and "not" is evidently omitted in line three from the bottom On p 48 "character" should be "characters"

Les Alpes Françaises Par Albert Falsan (Bibliothèque Scientifique Contemporaine (Paris J B Baillière et Fils, 1893)

WE cannot call this a successful book A mixture of condensed statistical information and of popular descriptive writing is not much better than a stirabout of Liebig's extract and of trifle-whip Fixity of purpose on the author's part is also wanting. Doubtless the French Alps cannot be separated from the rest of the chain, but for a book of only 286 pages all told, this contains too much about the Central, Pennine, and Eastern Alps The geological part is sketchy, and not always very accurate The author repeats the old mistake about the "variolite of the Durance forming a fringe to the euphotide," though the question was settled by the elaborate paper of Messrs Cole and Gregory, published in the *Quarterly Journal* of the Geological Society for 1890. The illustrations are numerous, few, however, of them are good, and several very bad There is no index. The work, in short, is a piece of book-making, characteristically French in style, and is not a valuable addition to the library either of the mountain-climber or of the man of science.

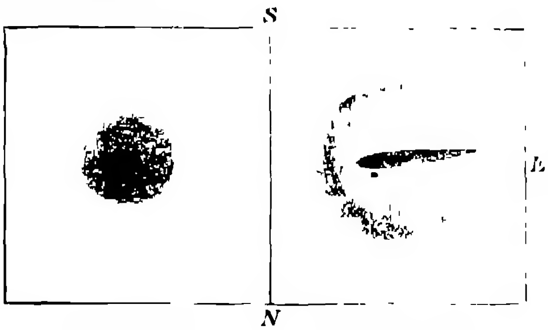
LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The New Comet

THE comet discovered by Mr. Holmes on November 6 was observed here on November 9 at 5h. 50m., and found to consist of a very bright circular nebulosity with central condensation. The diameter of the comet was 5′ 41″.

It was re-observed on November 16 at 10h. 45m., and its physical appearance seemed to have undergone a complete transformation. The diameter had increased to 10′ 33″, and the cometary material had become much fainter and more irregular. The nucleus was now in the form of a bright streak, and this was enveloped in a large faint coma. A small star was seen just N. of the W. extremity of the nucleus, and the latter seemed composed of knots of nebulosity.



Nov. 9, 5h. 50m. Nov. 16, 10h. 45m.

On November 19, 14h. 15m., the comet was seen again. Its general aspect was much fainter, and it exhibited a further increase in dimensions. I carefully determined its diameter as 14′ 30″, but the outlying portions were very tenuous and indefinite.

From Berberich's elements given in Edinburgh circular No. 33, it appears that the comet is moving rapidly away from the earth. The great increase in its apparent diameter is therefore not a little remarkable. On November 9 the comet was about 203 millions of miles distant from the earth, and its real diameter must have been 333,000 miles. On the 16th this had increased to 652,000 miles. By the 19th the comet's distance had become 217 millions of miles, and its real diameter 925,000. In ten days, therefore, the cometary material expanded nearly threefold.

Bristol, November 20. W. F. DENNING.

The Light of Planets

A FEW facts relative to this subject may be interesting. At Plymouth on August 12, about 9 o'clock, favoured with a beautifully clear horizon, the brilliancy of Mars was so great that it cast a distinctly black shadow on a piece of white paper from an ordinary walking stick held at a distance of 4½ inches; the outline of the hand, under the same conditions, was also easily perceptible. A faint, yet decided, darkening of the white cliffs of the shore was caused by a person standing upright—the slope being about 45°. The point of observation was at the extreme north-west of the Sound, and the splendour of the planet's light reflected from three or four miles of water is perhaps unrivalled.

The light of Jupiter has often enabled me, when using the telescope at a southern window, to make drawings and such references to books, &c., as were found necessary, without any other illumination. JOHN GARSTANG.

Rutherfurd Measures of Stars about β Cygni

IN order to prevent any possible misapprehension in connection with your notice (NATURE, vol. xlvi. p. 619) of Mr. Rutherfurd's measures of the stars surrounding β Cygni, may I call attention to the following?—The two stars of Argelander, 27° 3435 and 28° 3341, concerning which a doubt is expressed in my paper, are certainly lacking on the Rutherfurd plates. If they were present they would be very near the edges of the plates, and it is for this reason that I doubted whether we should expect to find them at all. The star numbered 28 in the Rutherfurd list, which appeared only as a sort of elongation of No. 27 on a plate taken at this Observatory, April 19, 1892, is one of the components of Σ2539, as was pointed out by Mr. Burnham in the *Astronomical Journal*, No. 268, and by myself in the same journal, No. 266. HAROLD JACOBY.

The Alleged "Aggressive Mimicry" of *Volucellæ*

MR. POULTON'S letter calls for few words in reply. I invited Mr. Poulton to produce observations in support of his statement that the two varieties of *Volucella bombylans* lay in the nests of the bees which they respectively resemble. To this invitation Mr. Poulton has not responded. He tells us that his account represented "a very general impression", that the same impression has been set forth in a showcase at the Museum of the Royal College of Surgeons, that even if he were mistaken it was well, if through his mistake the truth shall the more abound. It is thus admitted that in making that statement Mr. Poulton relied not on original authorities, but on the general impressions of others. That these impressions are in any sense correct there is as yet no evidence to show.

Compared with this, Mr. Poulton's error as to *Bombus muscorum* is of course comparatively trifling and it would be useless to pursue the matter, were it not for discoveries made in the process of unravelling it.

I pointed out that *V. bombylans* is common in nests of *B. muscorum*, a bee which it does not resemble. Mr. Poulton in reply maintains the opinion that *V. bombylans* var. *mystacea* does resemble *B. muscorum*. In defence of this statement he refers to (1) the showcase at the Royal College of Surgeons, where the resemblance is set forth; (2) a recent book, "Animal Intelligence," by Mr. Lloyd Morgan, where the resemblance is again asserted and illustrated by figures of insects in the similar showcase at the Natural History Museum.

In following up these clues I came to unexpected results. (1) There is at the College of Surgeons a showcase, as stated, illustrating the likeness of *Volucellæ* to humble bees. The label states that "the resemblance enables them [the flies] to escape detection." Two bees are exhibited bearing a good likeness to the var. *mystacea*, and, as Mr. Poulton says, they are labelled "*B. muscorum*." The one, however, is a worker of *B. sylvarum L.*, and the other is probably a male of the same species. Neither can be mistaken for *B. muscorum*, which they do not resemble.

(2) At the Natural History Museum bees of several species are shown beside the *Volucellæ*, with a similar statement that the resemblance enables the flies "to enter the nest of the bee without molestation." Not one of these bees is *B. muscorum*, nor are any of them said to belong to this species, for no names are given. Nevertheless, on turning to Mr. Lloyd Morgan's book, which I had not before seen, I find the statement (p. 90) that *V. bombylans* "closely resembles" *B. muscorum*, the passage continuing in the words of the Natural History Museum label. Figures are added showing the two forms of *V. bombylans* and two very different bees, *both* marked "*B. muscorum*." Now the figures are from *photographs* of certain specimens in the showcase, and on reference to the specimens in question, it appears that one of them is a yellow-banded humble bee (perhaps *B. hortorum*), while the other is one of the red-tailed humble-bees! These two are put out to match *V. bombylans* and the var. *mystacea* respectively, and of course have no likeness either to each other, or to *B. muscorum*, though both are referred to this species by Mr. Lloyd Morgan.

Mr. Poulton's choice of *B. muscorum* as a form resembled by the var. *mystacea* probably therefore arose from the wrong naming at the Royal College of Surgeons. How Mr. Lloyd Morgan came to call the two different bees by the name *B. muscorum*, which belongs to neither, I cannot tell. Perhaps this is in part an echo of Mr. Poulton's previous mistake.

Any one by reference to a collection of bees may easily satisfy himself that the common and ordinary *B. muscorum*, with its bright brown thorax, does not resemble *V. bombylans*, though this fly is common in its nests, just as *V. pellucens* lives in wasps' nests, though it does not resemble a wasp.

In the absence of direct evidence in its favour, and inasmuch

as it is inconsistent with many ascertained facts which were specified in my first letter, the hypothesis of "Aggressive Mimicry" should surely be withdrawn

No speculation is needed to enhance the exceptionally interesting facts of the Variation and the resemblances of the *Volucellæ* If a number of people will set to work on this problem in the way suggested, there is, I think, a fair chance of considerable results It was in the hope that such effort may be made that I drew attention to the matter, and I am really sorry that Mr Poulton should be hurt thereby. Nevertheless, I cannot but regard his account of the matter as an example of the way in which statements pass on from one writer to another, but prove on inquiry to be baseless WILLIAM BATESON

St John's College, Cambridge, November 14

Parasitism of *Volucella*

MR BATESON's interesting discussion of the relations between *Volucella* and the species of *Bombus* (NATURE, vol. xlvi p 585) suggests the following observations —The nest of *B muscorum* is made without much effort at concealment on the surface of the ground If accidentally disturbed the inmates set up a peevish buzzing, which, no doubt, answers the purpose of warning off ordinary intruders Yet *B muscorum* is of a patient and gentle disposition, and will put up with a good deal of maltreatment before using its sting Its sting, moreover, is less venomous than that of either of our other common humble bees. It apparently trusts to the reputation of its genus for protection from annoyance Such a creature would seem marked out by Nature as the very host to be imposed on by a parasite like *Volucella*, which, on the other hand, may need all its cunning to come round an irascible being like *B lapidarius*, or even like *B hortorum* And, in fact, as Mr Bateson points out, we find it multiplying abundantly at the expense of the first named bee, and less frequent in the nests of the other two Notwithstanding this, *B muscorum* appears to be certainly no less successful than either of the others in the struggle for existence W E HART

Optical Illusions

THE illusion of the Gothic arch in NATURE (vol xlvii p 31) is too good to have a rival, but simple Norman arches occasionally practise a deception of some subtlety In certain cases they seem to be of the Moorish horse-shoe form, this happens when the semicircle does not spring at once from the capitals of the Norman columns, but has a short intervening vertical space of masonry Architects are familiar with the effect, and call these arches stilted, they say the stilts are commonly vertical, although Norman walls have no doubt sometimes fallen away from the upright course I suppose the eye is quick enough to perceive that there is more than a semicircle, while the mind is gullible enough to infer that the curvature is continued In Winchester Cathedral there are some good illustrations of this appearance

A Strange Commensalism—Sponge and Annelid.

A CURIOUS case of what I believe to be definite commensalism between members of these two classes came under my notice the other day when collecting, and, as it is, so far as I know, a new instance in this interesting inter-relationship between animals, I venture to record it

Several large patches of crusting orange red sponge attracted my attention because of the peculiarly emphatic markings of what appeared to be the oscula They were suspiciously unlike anything spongiform, so I secured some good pieces of the sponge for further investigation Sections proved them to belong to the *Microciona plumosa* of Bowerbank, but the supposed oscula—which to the naked eye appeared as innumerable tiny black specks, each surrounded by a grey ring—proved to be, when the mass was teased out in water, in reality the ends of tubes inhabited by an eyeless *Leucodore* (*L cæca*, Œrsted). Fully forty could frequently be counted in a square inch.

The conclusion I come to after examination of a large number of specimens is that actual benefit is mutually given and received by each of the two messmates, the sponge gaining considerable support and extra consistency from the numerous comparatively wiry upright tubes There is also the question whether the excreta of the worms is of any food value to the sponge On the part of the worm, there is little doubt that it finds a valuable protector in the sponge which by the way is characterized by an intensely rank smell of garlic (warning odour?) I have seen no signs of this sponge being preyed upon by any animal, so we may conclude its protective devices of spicules, odour or taste are fairly successful A worm whose tube is sunk completely in its substance will naturally be very safely housed, and besides, the friendly water currents set in motion by the sponge cilia will bring much food matter to its very mouth

Bowerbank in his description (" Br Spongiadæ," vol ii p. 134) writes of a specimen as "permeated by some small tubular zoophyte which it has coated with its own tissues, and from these adopted columns defensive spicula are projected"—evidently the same as I describe above, though he makes the mistake of considering the tubes as those of zoophytes instead of those of annelids From this quotation, however, it is evident that the habit is widely spread, and not merely local. Here at extreme low-water the sponge grows exceedingly abundant, and the commensal worm seems always present

Jersey Biological Laboratory, November 10.

Induction and Deduction

MR DIXON says that there are "at least three different kinds of interpretation which may be put upon the proposition, [An isosceles triangle has equal angles at the base] It may mean (1) the triangle used to illustrate this proposition has equal sides, therefore it has equal angles, or (2) I have conceived a triangle which has equal sides, therefore I have conceived one which has equal angles, or (3) the connotation ascribed by the adjective isosceles implies the connotation 'having equal sides' [? angles]"

He goes on to observe that the difference between either (1) or (2), and (3) is "that this latter gives us no information about any real thing or concept, but only about what is implied by using certain terms," that is, about the connotations of "isosceles" and "having equal angles" ("equal sides" is of course a slip) But if connotation refers neither to the attributes of "real things" nor to "concepts" (which I suppose means ideas or notions) what can it be that we "imply" by using the terms *isosceles*, &c? If we do not mean things, nor attributes of things, nor ideas, do we mean anything which can convey or contain information?

In Mr Dixon's view the terms do convey information, but information which "clearly does not require to be based upon any real knowledge of things, but may be based solely on definitions of words" But must not definitions of words be based, in the last resort, upon knowledge either of things or of concepts—definitions of current words in some current sense, or even of strange words in strange senses—as *e.g* if I say Abracadabra means ixtra mixtra, and Triangle means abracadabra, and all abracadabras are four sided, and so on? With such propositions I may certainly frame syllogisms and arrive at "symbolical" conclusions, though I cannot see that I shall be doing anything to convey information or to advance thought

And when Mr Dixon says that the proposition "an isosceles triangle has two equal sides" has "wide applicability and usefulness" because we "often find things which can fairly be called isosceles triangles," it seems clear that he himself cannot have taken the proposition at starting in a sense purely "symbolic" (in his meaning of that word). If he did, it would be little less than miraculous that an entirely arbitrary definition should happen so to fit actual experience, especially when we consider that other equally symbolical mathematical propositions have an equal applicability.

I think it is probably true that we often do not depend, for our assent to complicated reasonings, on anything like full "realization in succession of the actuality of the relations and operations discussed", but I cannot admit that such reasonings do not refer to objects of experience or of thought Unless the terms did refer to something other than themselves, we could never assert S is P, or $x = y$

I unfortunately know nothing either of Pascal's theorem or of the intersections of two conics, but I think that in the case of the individual isosceles triangle, my intuition that the equality of angles at the base is inseparably connected with equality of sides, gives me ample ground for believing it to be "mathematically certain" that every isosceles triangle has equal angles at the base; it is self-evident that the one characteristic cannot exist without the other. That the isosceles triangle in question, if put under a microscope or tested by some micrometer, might turn out to be not "really" isosceles, seems to be a perfectly

irrelevant consideration, and I have never been able to understand the stress laid upon it by acute thinkers It is because the triangle is *as far as I can perceive* isosceles, that I intuit it to be *as far as I can perceive* equal angled

It has, I believe, been already explicitly recognized by certain logicians that a "symbolically" proved conclusion need not give any actual information about "real things" Indeed some go further, but I do not know that any have gone so far as to say that it would not give any information about ideas—although perhaps this may be the logical conclusion

Ice Crystals

YOUR correspondent, C M Irvine (vol xlvii p 31) will find letters on this subject in NATURE, vol xxxi pp 5, 81, 193, 264, 480, and in vol. xxxiii pp 461, 486

Prof (?) McGee's letter at p 480, of vol xxxi, gives a list of communications on the same subject in earlier volumes

B WOODD SMITH

The Late Prof Tennant on Magic Mirrors

SEVERAL scientific friends tell me that the late Prof Tennant, the well-known mineralogist, published some twenty or twenty five years ago a small pamphlet on Magic Mirrors Failing to find a copy even in the library of King's College, I invite the readers of NATURE to assist me to discover one

SILVANUS P THOMPSON

City and Guilds Technical College, Finsbury, November 15

On a Supposed Law of Metazoan Development

UNDER the title of "The Relations of *Larvæ* to Adult Forms," I recently read a paper before Section D at the Edinburgh meeting of the British Association The subject dealt with was of so extensive a nature, and the time available was so limited, that I fear much that was said must have appeared vague and ill-founded, if not entirely incomprehensible The material of the essay had, indeed, been prepared with the intention of devoting at least an hour to its delivery as it happened, I found myself under the necessity of cutting out whole passages of my notes whilst speaking

The few lines of the report in NATURE (vol xlvi p 404), convey a very inadequate idea of what I aimed at proving in the paper, and hence I am tempted to offer a fuller account to the readers of this journal

The subject of the essay furnishes a problem which must interest every embryologist, even though he should reject the conclusions to which observation and reflection have led me

In working out the complete paper so many novel and confirmatory points have been met with, so much of importance in the writings of the older embryologists, and more especially in the memoirs of Johannes Muller on the Echinoderm larvæ, has been unearthed, that an extension of the original plan of the work has been rendered necessary

My conclusions, moreover, are so much in conflict with prevailing doctrines that any haste in producing the full argument would be unpardonable, although a preliminary sketch by way of clearing the ground may be justifiable On a subsequent occasion an attempt would be made to show how the researches of recent years had, with a few notable exceptions (such as the work of R S. Bergh, J Kennel, and N Kleinenberg), tended away from rather than in the direction] of a recognition of the fundamental fact of an alternation of generations as underlying Metazoan development, in that they had been concerned, for example, with unnecessary attempts at homologizing the "mesoderm" and its mode of formation throughout the animal kingdom.

If the facts in support of my case should not be as complete as the published researches of the last thirty years on the ontogeny of very many animals might lead one to anticipate, the circumstance would have an obvious explanation.

With the death of Johannes Müller—a man whose brilliance as an embryologist was only surpassed by his greatness as an anatomist—there closed one chapter, and that one of the finest, in the history of comparative embryology What influence the publication of "The Origin of Species" had upon the subsequent progress of the science is too well known to need further expatiation here The pernicious search after pedigrees, initiated by Hæckel, led to an era of activity during which every fact with no apparent bearings on phylogeny was ignored As a consequence the work of Muller on the Echinoderm larvæ and the essay of Steenstrup on "Alternation of Generations" became more or less mere curiosities in the history of the science With little exception embryological speculation of the past thirty years has been naught else than a pursuit of will-o'-the wisps

It behoves us now to revert to the path along which Johannes Muller laboured

My own embryological conclusions, like those of contemporaries, have not hitherto been influenced by the *embryological* works of Muller, for it was not until after my paper had been read that a first study of the Echinoderm memoirs convinced me how nearly he had anticipated what follows

Before passing to the subject, one further remark may be permissible Owing to lack of time when reading the paper no opportunity offered itself for pointing out the analogy which obtains between the suggested mode of Metazoan development and the accepted fact of an alternation of generations in the life histories of all plants above the lowest Thallophytes Furthermore nothing was said about the mode of formation of the "mesoderm" in certain cases as one or more outgrowths of the endoderm, although the writer was fully alive to the explanation which from his standpoint could be offered This and other questions of a like character would receive consideration in the complete paper, in which it would be demonstrated that such things and processes need be neither "palingenetic" nor "cœnogenetic," but that the analogy of the formation of imaginal discs in *Insecta*, or in the *Pilidium* of the Nemertine, ought to suffice to account for them. As an instance, the formation of the mesoblastic somites in Amphioxus as evaginations of the endoderm may be only a mode in which certain parts of the adult are in that particular case laid down upon the larva

And now, after this digression, to return to the question under consideration Two modes of development have long been distinguished, viz, *larval with metamorphosis* and *fœtal and direct* Cases are known in which there subsists no homology between the larva and the adult, and even such in which the larva (*Bipinnaria asterigera*) is said to exist apart for a time after it has given rise to the Echinoderm In many such, moreover, the sole larval organ carried over to the adult is the alimentary tract, all other organs of the larva, such as nervous system, sense organs, locomotor and excretory organs, mouth and anus, &c, being replaced by new formations in the adult The new organs are thus not homologous with those of the larva, indeed, neither as a whole nor in its parts is the larva the homologue of the adult form, but the latter arises upon the former by a mode of asexual generation

The birth of the Nemertine on the *Pilidium*, and that of the Echinoderm upon the *Pluteus*, or upon the *Bipinnaria asterigera*, may be cited as examples, and the question may now be asked, What becomes of the larva when (*a*) food yolk is more or less abundantly acquired, and (*β*) when uterine development is initiated? Does the larva really disappear? Anticipating the sequel, it is asserted that the larva never vanishes from the development, but is always present in more or less disguised form In all cases the adult or imago would appear to arise upon it just as is so obviously the case in the examples previously cited

In the complete paper the modifications of the process throughout the Metazoa would be considered, in this place generalities alone can be dealt with If the larva be laded with food yolk it becomes transformed into a more or less obvious *blastoderm*, upon which the *imago* or mature form takes its origin Certain of the larval organs—such as those of locomotion—may then disappear, but others, such as the larval excretory and nervous mechanisms (*e g*, *Hirudinea*, according to Bergh's researches, *Ichthyopsida* from my own work) would persist Considerations of space do not permit me to enter fully into details regarding Molluscan development The published work on this group furnishes one with useful material in support of my case; and the group is an interesting one in connection with this question of the relation of the larva to a blastoderm In the *Mollusca* one can readily find all gradations from cases in which the adult is gradually substituted for a pelagic larva (*Patella*), through those in which the larva is somewhat burdened with food yolk (*Buccinum*), to others, finally, in which there is a large yolk sac and a blastoderm, on which the adult form arises (*Cephalopoda*) Incidentally I may remark that it was the study of some *Buccinum*

larvæ (*Veligers* with large yolk-sac) three years ago, which first afforded me a key to the solution of the problem of the relation of the larva to food yolk.

The *Arthropoda* are an important group, for larval forms widely prevail, especially, as is generally admitted, in the lower forms

The nature of the *Nauplius* is too big a question for discussion here, but Dohrn's conclusion that it is a transformed worm larva (*i e* one with *Arthropod* characters) appears to me to represent the truth. Two of the laws governing developmental processes appear to be that larval organs may be transferred to the service of the adult, and (more usually) that adult organs may become larval, or, as thay may be termed, *adaptational larval organs* Numerous instances of both these could be cited, and the three pairs of appendages in the Nauplius furnish us with a case in point

In the development of *Mysis* there is an example of the con version of the *Nauplius* larva, typically represented in the allied *Euphausia*, into a blastoderm upon a yolk-sac

I venture to attach most weight to the application of the prin ciple to the *Vertebrata*, for it is there that my own work has chiefly lain, and it is undoubtedly the obstacles offered by the phenomena of Vertebrate development which have hitherto prevented the enunciation of the "law of development as an alternation of generations" Larvæ are so commonly encountered among the Invertebrata that the wonder is that no one has inquired why they are so rare, in any guise, in the *Vertebrata*

In this latter division of the animal kingdom it becomes necessary to approach the problem previously stated as to the fate of the larva when uterine development is initiated

It may firstly be noted that larval forms, equipped with many adaptational larval organs, are to be encountered in cases with complete segmentation and but little food-yolk, *e g Marsipobranchii, Ganoidei*, and most *Amphibia*, while a blastoderm on a yolk sac is characteristic of *Elasmobranchii*, *Teleostii*, and *Sauropsida*, in which a larva, according to the common accepta tion, would not be very obvious

In all these cases, however, larval organs can be proved to exist, and, most important of all, there is a well-marked larval nervous system, which, while not certainly known to persist in any adult form, has been proved to degenerate during the ontogeny of all the oviparous *Ichthyopsida* as yet studied This apparatus is certainly neither a part of the adult nervous system nor homologous with the latter For an account of this mechanism the reader may be referred to the papers cited below [1]

Among other larval structures referred to when reading the paper, the curious degenerating cells on the blastoderm of *Pristiurus*, to which Prof Van Wijhe once drew my attention, and the knob on the blastoderm of *Torpedo*, as shown in Ziegler's beautiful models of the embryos of this form, and as described by H E and F Ziegler in the *Archiv fur Mikroscopische Anatomie*, Bd xxxix p 85, deserve mention

The yolk sac viewed as part of the larva would require detailed and extended consideration

It is gradually broken down by some ferment action on the part of the so-called merocytes,[2] which may possibly represent degenerating cells of the larva Only towards the close of life in the egg-capsule does the yolk appear to be digested by the alimentary tract of the Elasmobranch In some reptiles, according to Hans Virchow, the remains of the yolk-sac would appear to be cast off

In the discussion on my paper, one speaker, a personal friend, hinted that I had been led to look upon the yolk-sac as part of the larva from having followed some stray ends of "larval nerve fibres" on to that structure I had to confess my regrets that at that time I was unable to lay claim to any such observation, indeed, that having cut my embryos of *Raja batis* without any part of the yolk-sac appended, it had never occurred to me that the fibres described might pass to the yolk-sac Quite recently it has been seen that at any rate some of the larval "subepiblastic nerves" of the *Anat Anz* paper *do undoubtedly make their way to the surface of the yolk sac, lying just beneath its epiblastic covering* That a further confirmation of my conclusions is to be found in this observation goes without saying

[1] J Beard "The Transient Ganglion Cells and their Nerves in *Raja batis Anat Anz*, 1892, pp 191–206, and also, "The Early Development of *Lepidosteus osseus*," Proc Roy. Soc London, vol. xlvi. 1889, pp 115–118

[2] It is to H E Ziegler that we owe most of our knowledge of the way in which these merocytes, in their own degeneration and death, cause the elements of the yolk to become fit for absorption and assimilation

Some three years ago, when considering the "Inter-relationships of the Ichthyopsida," at a time when this larval question was prominently before me as a fascinating puzzle, I thought that the larva disappeared above the *Ichthyopsida* I was led to this conclusion by reliance on the accepted belief that larvæ are only met with in aquatic animals, more particularly in marine forms, and by the apparent absence of a larval nervous system above the *Ichthyopsida* My recent studies and the work of Froriep and Robinson have taught me that this was erroneous

The larva never disappears, however much it may undergo degeneration

It may even be doubted if there are not traces of the nervous system of the larva in the ontogeny of the *Amniota*, for there appear to be certain observations of Froriep on reptiles which may admit of interpretation in this sense, and my friend, Dr Arthur Robinson, tells me that he believes he has found traces of it in certain Mammalian embryos In mammals, as will be seen, the larva must be regarded as an internal parasite, and like such it would yield up its chief organs Some remains of its nervous system may, however, persist, as I have proved to be the case in *Mustelus vulgaris*, where the larva is almost as parasitic as in the Mammal The *Amnion* of the higher Vertebrata is probably also a larval structure with analogies to the organ of the same name in *Insecta*, in the *Pilidium* development, &c , as Kennel had previously insisted It would appear to me to be a membrane conditioned by the way in which the adult is formed upon the larva

Another important larval structure is the yolk-sac placenta of *Mustelus lævis* and of many mammals

In the latter the importance of this organ during a long period of fœtal life has been proved by Hubrecht and Robinson

The yolk-sac placenta may be explained as due to the fixation of a parasitic larva ; indeed, in mammals the larva has become a fixed internal parasite in the uterus, and its mode of life, like that of all internal parasites, leads to great degeneration

In this connection it may be insisted that it would be con trary to all that we know concerning the effects of the parasitic mode of life to suppose that a form might become a fixed internal parasite, and subsequently becoming freed from its host, attain to a higher grade of organization Yet this is what we must believe to hold good, if the current views of mammalian development be accepted as correct From my standpoint, on the contrary, the larva may become a fixed internal parasite, and none the less there may arise upon it a more highly organized and, when fully developed, free living form, the Mammal

Witness must be borne to the circumstance that Muller, Kleinenberg, and Kennel have already recognized that in some few divisions of the Invertebrata the mature form always arises upon a larva

In such groups as the Echinoderms an alternation of generations is now an obvious explanation of the facts, and when so magnificent an investigator as Johannes Muller proved this nearly fifty years ago, one asks, in vain perhaps, why modern embryologists, like Korschelt and Heider in their otherwise admirable "Entwickelungsgeschichte," ignore it The "recapitulation theory," and the question concerning the nature of the mesoderm have overshadowed the fact and concealed the recognition of an alternation of generations. But the so-called "law of ontogeny" itself is no explanation of the riddles of embryology, at most the recapitulation hypothesis holds for the development of organs, not of organisms

So far as the facts are available, Metazoan development appears to me to be by means of an alternation of generations, in that from the fertilized egg there arises an organism, the larva, upon which, in one way or another according to the circumstances of each case, a new form, the adult or imago, takes its origin

In 1855 the veteran zoologist, P. J. Van Beneden, wrote — "*La génération alternante est un phénomène qu'il faut chercher à faire rentrer dans la loi commune de la reproduction et non pas laisser comme une exception dans la science*"

In this essay an attempt has been made for the first time to prove that it is "la loi commune de la reproduction" in Metazoa,[1] and in concluding I cannot do better than echo the beautiful aphorism of Gœthe, which in a similar connection has already been commented upon by Steenstrup and Von Baer :—

"*Die Natur geht ihren Gang, und was uns als Ausnahme erscheint ist in der Regel.*" J BEARD

[1] It is not assumed that all the phenomena classified as "alternations of generations" are alike in their nature.

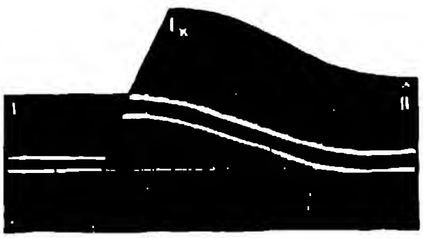
EXPERIMENTS ON FOLDING AND ON THE GENESIS OF MOUNTAIN RANGES[1]

Method of Investigation, Folding at Different Levels

DEFORMATION is represented in an exact manner, if we note the movements executed by certain points, and the position of these points before and after deformation. I divide the surface of sediments into squares (scale = 0 1m), and this division passes in vertical direction through the whole system, so that every stratum is divided into prisms or cubes of known dimensions and positions At every moment of deformation we may note the movements of any point or line, and the deformation of any square or prism Especially the deformations of the surface and of normal-profiles is important The position (orientation) of prisms must agree with the direction of pressure

FIG 1

FIG 2



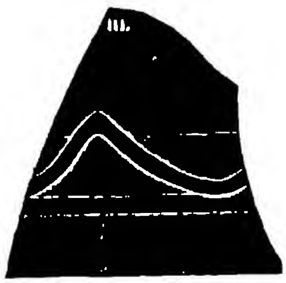


FIG 3 FIG 4

FIG 5 FIG 6

FIG 7 FIG 8

I employed in every case muddy material (clay, plaster of Paris) Example We note the position of prism I in Fig 1, and its position and deformation are noted in Fig 2, I is pushed forward and deformed into I x B = the "Basal plane," is parallel to the base or surface No = Normal plane, is situated vertical and in the direction of pressure L = Longitudinal plane, vertical and at right angles with No, agrees with extension of strata

N = normals, *i e*, perpendicular scale-lines

Explaining experiments The sediments I, II, Fig 3 (exp 203, clay with a layer of plaster) are subjected to lateral thrust The higher parts are more moveable and get deformed more than the lower strata

I goes to I x, it is compressed and elevated, II in contact with the wall is elevated a little (to x) The dark middle stratum I produces a flat fold In Fig 4 compression and elevation is more intensive The normals N (originally vertical lines) are deformed into curves

When at the surface very plastic material dominates (mud), the surface after deformation remains flat, whereas in the deeper parts intense folding may have taken place If we push a muddy mass, covered by plastic layers, the latter get folded, whereas the deep parts are only thickened

The movements and deformations of N (normal profile) are of especial importance

Fig 5 (exp. 292), paper between muddy strata The direction and deformation of normals show the typical movement of strata in each case

In Fig 6 a plastic layer (white) lies between muddy sediments After the deformation only the white layer is folded

In Fig 7 folding towards the deeper parts is more intense, but the muddy surface remains flat In all these cases strata get thickened The thickness measured in a fold-chain does not correspond to the original thickness The strata of the Appalachian Mts, having to day a thickness of 10 km in a certain section, originally had different dimensions If measured along the fold-limbs the number is by far too small, as here the strata are rolled out, in the synclines, on the contrary, strata appear much thicker than they were at the beginning

If plastic sediments are driven by their own weight, *i e* if they *glide* over an inclined plane against an obstacle.

[1] Extracted from *Geologische und Geographische Experimente*, by Dr E Reyer 1 Heft Deformation und Gebirgsbildung Leipzig, 1892 See also "On the Causes of the Deformation of the Earth's Crust," by the same Author. (NATURE, vol. xlvi. p. 224)

there occurs a deformation, as in the case of lateral pressure Deformation in the first case is greatest near the obstacle

Anticlinal Rupture, Pinch-folds, Squeezing, Pseudo-eruptive Processes

Pushing produces compression In the anticlines tension effects rupture In the fold-limbs plastic material is squeezed, rolled out, and pushed towards the clines (synclines or anticlines)

In the synclines of great dimension plastic material is pushed together and pinch-folds result

Passing over some of the experiments which illustrate the dislocations described by Heim and Margerie we come to more complicated examples

Figs 5-8 show "pinch folds" in very plastic material, which are spread and thrust over, so that they form a flat bottom in the syncline

Other experiments illustrate a pinch-fold with ruptural deformation Usually the intense deformation is confined to the district of the pinch-fold, in very plastic material and under variable pressure the stratum in every part gets greatly altered If we divide the strata into differently coloured prisms we see in each profile at once the deformation at every point Often deformation is so intense that we may denote it as kneading

The deformation shows how a vertical dyke gets influenced by folding

If a plastic stratum is inserted between rigid strata, the former often gets injected into ruptures of the rigid sediments, mud-dykes, pseudo eruptive processes (Reyer, "Theoret Geol" p 330)

Movements of Normals and of Waves Overthrust, Thrustplanes [1]

In a fold-chain the higher masses are pushed over the lowland, which does not yield sufficiently The result is an overthrust, often combined with pinch-folds, Fig 11 (exp 207) The inverted strata dip against the direction of the push

Fig 9 = original thickness of strata In Fig 10 folding begins Fig 16 last stage Normal measure at the base = 1 dm

In most cases shifting occurs between the strata, especially in upheaved strata, and we see gaping fractures, which cross a stratum and then follow again the planes of stratification (intrusive sheets)

The gliding movement may sometimes cause an extrusion

Fig 12 plan, and section Fig 13 (exp 278)

An overthrust-fold is nearly squeezed off (compare position of normals) An intense thrust generates ruptures, and the strata glide in the form of scales over the lowland

Fig 14 (exp 242) a fault in the base, over which a complex of sediments glides, the lowland sinks and the higher masses now push with increased force towards the plain ("Vorfaltung" *Suess*)

Squeezing and Tearing, Deformation of Included Masses.

Squeezing and tearing often occur in regions of great difference of tension or pressure. In the anticlines strata are torn, the direction of ruptures is converging towards the axes (axipetal direction), in the limbs there occur squeezing and tearing

[In the latter part of his memoir, Dr Reyer shows how his experimental methods may be applied to the explanation of such complicated questions as very complicated overthrust faults, the appearances presented when much folded and faulted strata are subjected to erosion, the occurrence of undisturbed tracts associated with much folded ones, and the formation of lake-basins]

[1] Compare the excellent experiments of Forchhammer (Sanddruck, 1883), Cadell (NATURE, vol xxxvii, p 489). Those authors experimented with powder material, whereas I operate upon plastic materials.

GALILEO GALILEI AND THE APPROACHING CELEBRATION AT PADUA.

ALTHOUGH Galileo began his career as a teacher in Pisa, and occupied for three years the Chair of Mathematics there, and was inscribed until his death in the list of the teachers of that University, nevertheless the University of Padua was the one to which from the beginning he had aspired, and in which he exercised with the greatest efficiency his powers as a man of science and

a lecturer Now the University and citizens of Padua desire to celebrate the tercentenary of the day on which he delivered his first lecture

When elected by the Venetian Republic to the Chair of Mathematics on September 26, 1592, he asked to be permitted to delay the beginning of his lectures in order to prepare his inaugural oration, and to attend to some domestic duties which required his presence in the country, thus it was December 7 when he first occupied the professorial chair This date is confirmed by a letter, written from Padua to Tycho Brahe, and published by the latter in his celebrated "Astronomiæ Instauratæ Mechanica," and Galileo's chair is amongst the most precious relics preserved by the ancient and famous University A week later he began regular lectures, which he continued to give for eighteen years

In the ancient archives of the University the rolls of the time when Galileo taught are in a great measure preserved, and from these we learn that, in accordance with what was prescribed by the statutes, he alternated astronomical teaching with that of Euclid and the mechanical questions of Aristotle

The didactic activity of Galileo was not altogether confined to public teaching, it was extended, in conformity with the prescriptions of the statutes, to private teaching How much influence he exercised in this manner is easily seen from his autographic records which have come down to us The importance of these private lessons will appear all the greater when we reflect that they dealt not only with the subjects discussed in public, but with matters connected therewith From contemporary documents we perceive with what precision all such subjects were taught by Galileo the use of the geometrical and military compass, fortifications, Euclid, perspective, mechanics, geography, arithmetic, geodesy, and cosmography As to the students, they were for the most part foreigners, namely, Poles, Germans, Danes, French, and Flemings In the lists of private scholars we find an "illustrious Englishman"—very probably Richard Willoughby, who was vicar of the University of Law and Councillor of the English nation In his honour a stone on the wall of the University is still preserved, and, a still greater honour, a copy of the famous "Difesa" is dedicated to him with Galileo's autograph Two Scots should also be particularly mentioned as amongst Galileo's pupils, these were John Wodderborn, who wrote a confutation of the libel of Horky against Galileo, and dedicated it to Henry Wotton, the English ambassador at Venice, also Thomas Segget, Councillor of the Scots nation, in whose "Album Amicorum," now in the Vatican library, there is also an autograph of the great philosopher It was Seggett who received from Kepler a copy of Galileo's "Sidereus Nuncius," and who in the appendix to the "Narratio" of the same Kepler published the epigrams containing the famous "Vicisti Galilaee."

Besides the ordinary public and private lectures, Galileo held in the University some special public lectures, of which we may mention those upon the new star of October, 1604, and those in which he announced his astronomical discoveries.

Every one tried to render Galileo's stay in Padua as pleasant to him as possible His freedom in teaching was absolutely complete, and the strong arm of the Venetian Republic defended the professors of the University from the power of Rome In Padua, from the first, Galileo was received with the greatest kindness, he found many faithful friends both in Paduan society and among the Venetian patricians. His salary was repeatedly increased, so that, after the presentation of the telescope, it rose to thrice the amount conceded to his predecessors Galileo came to Padua at the age of twenty-eight and remained there during the eighteen years which were the best of his life, those in which he showed the greatest scientific fertility, and in which he prepared the way for all his future labours We have now reached the completion of the three centuries since Galileo began his teaching in Padua, and the University naturally considers that the anniversary should not be allowed to pass without honourable notice

It is fitting that a celebration relating to the work of a man of science of the highest rank should have a truly national character The King of Italy has therefore associated himself with the movement, and the Universities, the polytechnic institutions, and the most celebrated academies of the world have been invited to send delegates Already the Universities have in great number responded to the appeal Mr J Norman Lockyer will represent the Royal Society of London, and Mr George Howard Darwin the University of Cambridge

As once scholars from every part of Europe came to Padua to hear the celebrated master, so now from every part of Europe the most celebrated come to honour his memory

ANTONIO FAVARO
(Director of the National Edition of Galileo's Works)

A NEW METHOD OF TREATMENT FOR CHOLERA

IN the *Times* of the 18th inst there appears an account of a new method of treatment for cholera which, should it ultimately be proved to be founded on accurate observation and well-authenticated cases, gives results seldom, if ever, obtained by any other method during the height of a cholera epidemic Before criticizing this new method let us see what are its essential features

In cholera there are two main, and evidently different, indications for treatment it is usually maintained that the primary etiological factor in the disease is the "Comma" bacillus, which under certain conditions is enabled to live and multiply in the human intestine There, living as an anærobic organism, it thrives especially well if, through inflammatory reaction, certain of the albuminous constituents of the blood and lymph are thrown into the intestinal tract From or in this favourable culture medium it is enabled to produce a most virulent and readily diffusible poison, which has not only a powerful local action, but also a power common to these micro-organismal poisonous products, of acting on the nerve centres In this way, so long as the bacillus remains alive, the supply of exudation into the intestine is kept up by the local irritant action of the poison, this being accompanied by a rapid abstraction from the blood of its watery elements, and at the same time a supply of the powerful "toxine" is maintained and diffused throughout the body Except in very severe cases, where the paralyzing effect of the toxine on the individual cells of the tissues is extremely rapid and well marked, an effort is made by these cells to destroy the bacilli and by the special secretory cells of the intestine, kidney, and other excretory organs to eject this poison from the body Not only so, but if the poison can, like the bacillus, be confined to, and eliminated directly from the intestine, the bacillus soon becomes unable to live, and as it multiplies and produces its toxines it is killed off by the various agencies that are conspiring to destroy it.

Up to the present all conceivable methods of treatment have been tried, and almost every drug has been pressed into the attack on cholera, but the most successful and rational attempts have been those in which the destruction of the bacillus and its poison have been aimed at, especially if this has been accompanied by the use of means for promoting the rapid secretion

and excretion of the poison from the body Here as in the specific infective diseases generally our want is an antiseptic that will help to kill bacteria, directly or indirectly, and that will not damage, but will even give healthy stimulation to the tissue cells

In this new method of treatment it appears to be claimed that in certain periodate salts we have substances which act not only on the bacillus (as bactericides) in the alimentary canal, but also directly on the "toxines," bringing about their oxidation into less complex and more stable non-poisonous substances, which can be readily excreted by the kidneys, or may be got rid of directly from the intestineal tract It is also claimed, but apparently with very little reason, that the periodate salts have some direct action on the nerves, this, however, is mere conjecture, and the arguments offered in support of this hypothesis are far from convincing In the *Times* article it is stated that "there are two principal drugs employed—the crystals of periodate" (of what?) "which are powdered, and a periodate of iron The last-named is used in such cases as demand an extra strong nerve or cardiac stimulant treatment, and where there are severe neuralgic symptoms The first is used in several ways first as a powder to disinfect the alimentary tract, second as a plain water solution, prepared by boiling copiously, and used as a beverage by patients to wash out the stomach in severe vomiting, which abates as soon as the walls of the stomach begin to absorb the fluid, whereby the nervous energy is stimulated, in from two minutes to an hour or two, for transfusion under the skin, and, in cases of collapse, into a vein, for restoration of the suspended circulation of the blood, third, an acid solution of the powdered crystals of much greater strength than the plain watery preparation is found to stimulate the liver and kidney and gall bladder, promoting a free secretion of bile"

It is supposed that by this treatment the body is flushed and sweetened as it were, and so far the treatment would be rational enough could it be thoroughly carried out Far greater reliance might have been placed on the evidence put forward had the initiator of this treatment been content to place on record facts, instead of attempting to formulate a theory for everything, as his theories whilst giving evidence of his undoubted enthusiasm, indicate only too plainly that where he gets beyond the use of the test tube he is compelled to draw largely on his imagination for many of his facts and most of his explanations

As regards the percentage of recoveries mentioned, it must be remembered that towards the end of an epidemic the fatal cases always form a much smaller proportion of the total cases than during the earlier stages of the outbreak. The people most susceptible to the attack of the disease, *i e* those with damaged hearts, kidneys, and lungs, have already succumbed, the weaklings have been cleared out of the way, and but the fittest and comparatively well-nourished remain Attempts have been made to ameliorate the wretched surroundings of those most prone to take the disease, the poor are better fed and better able to withstand the ravages of the cholera organism, the "cholera fright," at first a most potent factor in the preparation of patients for cholera, has to some extent subsided, the cases are not only much less numerous, but they are of a milder type and a less fatal character Then, too, after the first few batches of patients come in (amongst which the mortality is always extremely high) there ensues a kind of panic amongst the authorities, and the treatment consists of little more than placing the patient in a ward along with others suffering from the same disease, in order to get them away from their healthy companions; other treatment is for long of the most meagre description, and it is only when hygienic conditions have been improved, mode of transport organized, and hospital accommodation arranged that the medical authorities have time to devote to the treatment of individual patients As soon as patients do obtain such individual treatment and attention the percentage of fatal cases rapidly declines

These periodates, analogous salts to the chlorates, are apparently the direct heirs to the qualities that at one time were ascribed to the chlorates, for which it was claimed that they had great power of supplying oxygen for the transformation of poisonous products in the body It was found, however, that these chlorates when administered in large doses made their appearance in the secretions in a very slightly altered condition, not only so, but they exerted an exceedingly deleterious effect on the blood, reducing the hæmoglobin to methæmoglobin, and stopping the respiration and bringing about a fall of the blood pressure to zero This periodate, which is apparently extremely insoluble except in acids, may be tolerated in small doses, but its physiological action, especially when administered in large doses, can scarcely yet have been studied

As to the action on the kidneys through the nervous system, we have as yet little or no evidence that there is any direct action of the nerves on the secretion by the kidneys except through the vaso-motor system It is usually maintained that the suppression of urine in cholera is due primarily to the extremely low general blood-pressure owing to the rapid abstraction of the fluid elements of the blood brought about by the passage of watery stools, but also in part to the irritative action on the secreting cells of the kidney of the cholera toxines, as a result of which secretion is more or less paralyzed In order to overcome this stoppage of excretion by the kidneys, the practice of injecting warm normal saline solution has in recent epidemics been practised with some success, especially when boldly and repeatedly carried out This treatment has the additional advantage that it not only supplies fluid to the parched tissues, but also increases the volume of blood on which the heart may contract and helps to wash away the specific poison It is utilized to a very great extent in the new method described in the *Times*, but whether the periodates are better than common salt as a substance with which to raise the specific gravity of the warm water, yet remains to be determined As yet the details supplied are far too meagre to allow of any definite opinion as to the value of this periodate treatment being arrived at

It is fortunate that we have no cholera epidemic with us at present, otherwise we should have a right to complain that the *Times* has been made the medium through which what must be a very imperfect—and certainly from a physiological point of view—incorrect theory, has been presented to the public, and it will be well to await the exact accounts of those who have been entrusted with the carrying out of the treatment in the wards of the Seamen's Hospital, and the results of fuller chemical physiological, and therapeutic experiments, minutely detailed and recorded, before we allow ourselves to be buoyed up by hopes which, previous experience has taught us to fear, may be very summarily and completely dashed We hope that we may have no opportunity of testing the value of this new treatment in England, but there is too much reason to fear that, abroad, opportunities in abundance will be afforded during next spring and summer.

How much of the success obtained in Hamburg is to be ascribed to the factors above mentioned, and how much to the careful treatment and nursing of confident medical men, inspired by the enthusiasm of the "inventor" or promoter of the "periodates," it is difficult to say, and we shall await with interest, but with well disciplined and chastened expectation, the report of the German doctors mentioned in the *Times* on the results of their observations

NOTES

MR W H PREECE, F R S, has been appointed engineer-in-chief and electrician to the Post Office

A CIVIL LIST pension of £75 per annum has been granted to Mrs Dittmar, widow of Dr William Dittmar, F R S, Professor of Chemistry in Anderson's College, Glasgow, in consideration of her husband's distinguished services

THE Linnean Society, at its ordinary meeting on the 17th inst, adopted an address of congratulation to the Rev Leonard Blomefield on the completion of the seventieth year of his Fellowship of the Society, he being the father of the Society, having joined it on November 19, 1822, and being now in the ninety-third year of his age At the time when Mr Blomefield (then Jenyns) became a Fellow of the Linnean Society, it was still under the presidency of its first President, Sir J E Smith, he was also an original Fellow of the Zoological Society, and is one of four survivors of the founders of the Entomological Society He joined the British Association in the second year of its existence Mr Blomefield was Mr Darwin's senior at Cambridge, was closely associated with him in his zoological researches until Mr Darwin's death, and was one of his most frequent correspondents His early bias towards the study of nature was due to his reading White's "Natural History of Selborne" while at Eton This was then a very scarce book Having borrowed a copy of it from a friend, being uncertain whether he should ever see it again, he copied the whole of it in manuscript with his own hand The address of congratulation was moved by Sir William H Flower, seconded by Mr St George Mivart, and acknowledged by the Rev Geo Henslow, a nephew of Mr Blomefield

THE following gentlemen have been appointed to form the Fishery Board for Scotland —Mr Peter Esslemont is Chairman, the other members being Mr John Guthrie Smith, Sheriff of Aberdeen, Kincardine, and Banff, Mr George H Thoms, Sheriff of Caithness, Orkney, and Shetland, Mr Dugald M'Kechnie, Sheriff of Argyle, Mr William Boyd, solicitor, Peterhead, Mr James Johnston, fish curer, Montrose, Mr William Anderson Smith, Ledaig, Professor Mackintosh, St Andrews, and Mr J Ritchie Welch, St Andrews

THE Royal Microscopical Society will hold a *conversazione* in the Banqueting Saloon, St James's Hall Restaurant, on Wednesday, November 30, at 8 p m

THE annual dinner of the Institution of Electrical Engineers was held on Friday evening at the Criterion The president, Prof W E Ayrton, F R S, was in the chair Responding to the toast of the Learned Societies (proposed by the chairman in a humorous speech), Prof G F Fitzgerald said that learned societies were never more flourishing than they were now The co-operation of theory and practice had been the fruitful parent of nearly all the advances of the present generation We had such enormous stores of energy at our service that almost immeasurable prospects were open for the material improvement of man's estate Mr Latimer Clark (past president) proposed "The Engineering Societies." He said these societies were in danger of being overlooked They first perfected the steam-engine, then improved manufacturing implements, then the steam-boat. The engineering societies had done much more to promote the great prosperity of this country than the politicians who had so wickedly usurped the greater part of the credit Dr. W Anderson responded The Chairman then proposed "Our Guests," with which he joined the name of Mr Mundella, President of the Board of Trade, who exercised a sort of parental supervision over them all No doubt sometimes there was a little disposition to grumble, as children did occasionally, at the form in which that fatherly affection displayed itself But, whatever their feelings about the Board of Trade, there was no doubt about their feelings with respect to its president Mr Mundella, in response, said that, whatever grievances the engineers might have against the politicians, his withers were unwrung The Board of Trade might have given the electrical engineers some trouble if so, it was not due to him Mr Latimer Clark had complained of the appropriation of all the credit of material progress by the politicians Let them halve the difference The politicians had, at all events, appointed Dr Anderson He was speaking to a comparatively young institution, but it was to one which was growing more and more and would advance to still greater degrees of greatness The Board of Trade owed much to the electrical engineers, who had devised systems and methods of the utmost value He believed we were now at the outset of a great advance in the science of electric lighting Progress would be assured when they could assure shareholders of a reasonable dividend Two millions had already been expended in the metropolis, and we might soon hope to overtake the United States and Continental countries, which were, he feared, still to some extent in advance of ourselves The Board of Trade had no desire to hamper the progress of electricity by needless rules, and hoped that in this, as in all other branches, science would go on its beneficent course untrammelled by any unnecessary regulations Sir James Sivewright, Commissioner of Public Works, Cape Colony, proposed "The Institution of Electrical Engineers," to which the president briefly responded

WE print elsewhere an abstract of a most interesting paper on stability and instability of viscous liquids, read before the Royal Society, by Mr A B Basset It presents in a new way the various problems involved in the calming effect of oil poured on troubled waters

PROF J E HUMPHREY, of the Massachusetts Agricultural Experiment Station, is about to visit Jamaica for the purpose of making a study of the algæ and fungi of that island

THE weather during the past week has, upon the whole, considerably improved, it has been mostly fine in the southern and eastern parts of the kingdom, but less settled in the west and north Temperature has been decidedly lower, and over the central and eastern parts of England sharp frosts have been experienced The distribution of pressure has been generally cyclonic over these islands, but over the west of Europe the anticyclonic has still held its ground The eastern portion of England has been brought under the influence of both high and low pressure systems, being situated about mid-way between the cyclones which have skirted our western coast, and the anticyclone over western Europe. These conditions were accompanied by very quiet weather, with a good deal of local fog On Sunday a depression, which passed along the Irish coast, caused southerly gales on that and following days in the south of Ireland and the English Channel, with very heavy rainfall in Ireland, the amount measured at Roche's Point on Monday and Tuesday mornings was nearly 2 5 inches Towards the close of the period the European anticyclone was spreading westwards, and the barometer was high and uniform over Great Britain For the week ended the 19th instant the official reports show that the rainfall was considerably in excess of the average over Ireland and the south of England From the beginning of the year the deficiency in the latter district is 2 3 inches, and in the south-west of England 8 4 inches, or more than 23 per cent of the average amount Bright sunshine was

again very deficient over the whole of England and Scotland, in the south-west of England the duration only reached about 2 per cent of the possible amount

THE *Pilot Chart* of the North Atlantic Ocean for November contains some interesting reports of the drift from some portion of the coast of the American continent to mid-ocean of a mass of forest growth resembling a floating island It was first seen on July 28 in lat 39° 42′ N, long 64° 20′ W On September 19 the *Roman Prince* reported it in lat 45° 29′, long 42° 39′ as "a clump of bamboos about 30 feet in diameter and 20 feet high" Between these two dates the little island drifted more than 1000 miles in an E N E direction The month of October was very stormy in the North Atlantic, from the tracks laid down on the chart several of the storms seem to have moved along very abnormal tracks, and this fact has probably some connection with the very severe weather experienced in this country In the early part of the month a hurricane formed in very low latitudes, and passed over Trinidad on October 6 into the Gulf of Honduras, and possibly into the Gulf of Mexico It is unusual for a hurricane to occur in such low latitudes in the North Atlantic Very little fog was reported, and no ice south of the 50th parallel

SEVERAL shocks of earthquake have been felt lately in the island of Ponza On the evening of November 16, according to a Reuter's telegram, the walls of several houses were slightly cracked by one of these shocks, which was accompanied by subterranean rumblings No one was hurt, but alarm spread rapidly among the inhabitants, half of whom took refuge on small vessels lying along the coast, while the remainder encamped on the beach

THE *Age Herald* of Birmingham, Alabama, gave on October 28 an account of a great meteor which had been seen on the previous day to pass over that city and disappear in a south-westerly direction. We learn from the Mobile *Daily Register* of October 29 that at Gadsden a brilliant meteor was seen at the same time, that is, between five and six o'clock on the afternoon of October 27 It passed near the zenith Two young men employed in the *Daily Register* office at Mobile saw at the same hour in the afternoon a bright meteor in the north-west It was about 45° above the horizon When it neared the western horizon it explòded like a sky rocket

A MALE gorilla (*Gorilla gina*) has lately been acquired by the Berlin Aquarium He is larger than any gorilla that has yet been brought to Europe. He is supposed to be eight or nine years old, and was for six years in the possession of a chieftain on the Gaboon Captain Clarke brought him to England. The *Naturwissenschaftliche Wochenschrift*—which estimates the value of this "splendid animal" as not less than 10,000 marks—says he has not yet shown any very friendly feeling for man.

IT appears from a report issued by the Board of Trade that the examinations and comparisons of the Parliamentary copies of the Imperial standards show that no measurable change has taken place in the length of the Imperial standard of measure The Imperial standard pound weight appears, however, by comparison with the Parliamentary copies of the Imperial standard pound, to have decreased in weight since it was restored and legalized by the Standards Act of 1855. The amount of diminution in the weight of the Imperial standard pound would not be appreciable in trade, and had probably arisen before the year 1872, but the Board of Trade are taking into consideration the question of restoring this standard in the manner provided by Section 6 of the Act of 1878.

THE South Australian Government has issued a full report of the proceedings of the Rust in Wheat Conference during its third session, held in March of the present year Among the resolutions adopted by the Conference was one to the effect that a practical system for the production and distribution of rust resisting wheats suitable to different districts should be immediately established, and that this system—subject to modifications needed by each colony—should be conducted on the following lines —A central station for each colony for the preliminary testing of new wheats introduced into the colony, for the production of new varieties by cross fertilization and by selection, and for the distribution of suitable wheats thus obtained to representative districts of the colony, to be there subjected to a sufficient test, and, if necessary, fixed in their characters by farmers and others competent for the work, and that such wheats as pass satisfactorily this test should then be distributed to the farmers around in such a manner and by such agency as would be most suitable to the conditions of each colony The Conference will meet at Brisbane in 1894 It is hoped that in the meantime the various colonies will publish the results of the experiments which are to be carried on during the coming year.

MR XANTHUS SMITH, a well-known American photographer, has formed a high opinion of some of the work done in photography in England "There is no doubt," he has lately said, "that the English photographers excel us Americans in landscape photography, and mainly for two reasons, the first being their appreciation of atmospheric effects, which is no doubt a result of their moist climate, and second, the extreme pains which they are willing to take in order to secure an effective picture" The *Photographic News* considers it 'quite a comfort to record a statement like this, not because it praises English work, but because it acknowledges the pictorial effect often obtainable from a misty atmosphere" "Those who are ignorant of the subject," adds our contemporary, "invariably credit the alleged superiority of foreign photographs to the greater clearness of the atmosphere which is supposed to prevail outside the confines of Great Britain"

AN interesting case of a wild rabbit living in an almost tame condition is recorded by Helen J. Murray in the current number of *Nature Notes*, the Selborne Society's magazine Mrs. Paul, a fisherman's wife, living in a hut between Ardnahein Farm and the mouth of Loch Goil, deserves the credit of having achieved this result. The rabbit was brought in when very young by a cat, and reared by Mrs Paul, from whose hand it still feeds It now spends part of its time in the woods, and part on the low sloping roof of the hut among the pigeons, or at the door among the fowls It is shy in the presence of strangers, but quite friendly to the fisherman's wife

IT seems that since the appearance of the Russians at Tashkend a beginning has been made there in the cultivation of the better kinds of tobacco According to the *Journal of the Constantinople Chamber of Commerce*, quoted in the Board of Trade Journal, first trials were made by a commercial firm trading between Persia and China. The satisfactory result of this cultivation, due to the favourable atmospheric conditions and to the fruitful qualities of the soil, attracted many Russian imitators, and very soon the native population followed their example, so that the area of land devoted to the cultivation of tobacco now comprises sixty-three deciatines, and it is expected that it will not stop at that point

THE new number of *L'Anthropologie* contains an interesting article by M. Emile Cartailhac, on the Stone Age in Egypt. It is the first of a series of papers on the stone age in Africa. English readers will be glad to see that in this instalment M Cartailhac does ample justice to some of the discoveries of Mr Flinders Petrie, the value of whose work has also been fully

recognized lately in the German periodical *Globus*. Another good paper in *L'Anthropologie*, by M Louis Siret, deals with the end of the Neolithic epoch in Spain.

PROF McINTOSH's paper on the Scottish Fisheries, to which we referred at the time it was read at the Edinburgh meeting of the British Association, has now been issued as a pamphlet by Messrs John Leng and Co, Dundee The paper presents a clear and interesting account of the Scottish Fisheries, chiefly in their scientific aspects, during the decade 1882 92

THE Cartwright Lectures, 1892, delivered by Dr Henry F. Osborn, Professor of Biology in Columbia College, have been reprinted from the *American Medical Record* They deal with "present problems in evolution and heredity" In the first lecture Prof Osborn discusses the contemporary evolution of man, in the second, difficulties in the heredity theory, in the third, heredity and the germ cells

THE Kansas University has started a "Quarterly," which is to be maintained as a medium for the publication of the results of original research by members of the University In the second number, which we have just received, Mr E H S Bailey has an interesting paper on the Great Spirit Spring Mound The Great Spirit Spring is in Mitchell county, Kansas, on a conical limestone mound 42 feet high, and 150 feet in diameter at the top The pool itself is a nearly circular lake about 50 feet in diameter, 35 feet deep, and the water rises to within a few inches of the top of the basin There is a level space on all sides of the spring so wide that a carriage can be readily driven round it Within about 200 feet of the mound is a limestone bluff, which rises perhaps 20 feet above the level of the spring Mr Bailey suggests that the mound may have been made by successive deposits from the spring Although the mound is plainly stratified, this need not, he thinks, interfere with his theory, as the water may have been intermittent in its flow The rock is very porous, and on being ground to a thin section is shown to be concretionary in structure. It is of just such a character as might have been built up by deposition from the water, as it contains the least soluble constituents of the water The process of solidification would be assisted by the silica in the water, forming insoluble cementing silicates An analysis given by Mr Bailey shows that there is abundant silica in the water for this purpose

A PAPER presenting a revision of the species of Coryphodon, by Charles Earle, printed originally in a Bulletin of the American Museum of Natural History (vol iv, No. 1), has now been issued separately The recent expedition sent out by the American Museum of Natural History to the Bad Lands of the Wahsatch formation of Wyoming was successful in procuring some valuable Coryphodon material The entire collection was placed in Mr Earle's hands for identification and study He has been surprised by the large number of species which have been proposed, and finds upon studying and comparing the types that a great reduction in the number of species should be made.

WITH a view to determining the phylogenetic position of mammalian hair, Herr Maurer has recently been studying the sense organs of the skin, feathers, and hairs, and their mutual relations (*Morph Jahrb*) His researches render more evident the profound difference that exists, both in early development and in later behaviour, between mammalian hair and feathers Morphologically, they are to be regarded as quite different organs. Are the hairs, then, *sui generis*, or may they be brought into relation with other epidermis-forms? From studying the lower vertebrates, Herr Maurer considers that the skin sense organs of amphibia afford the ground on which hairs are developed. The complex relations of the root sheath of the hair allow thus of an easy explanation Further, as to the relation of mammalia to other vertebrate groups, as indicated by forms of integument, Herr Maurer is of opinion that mammals become separated from Sauropsida and draw closer to amphibians, thus confirming a view based on other points of organization

FLUORSULPHONIC ACID, $SO_2(OH)F$, has been isolated by Prof Thorpe and Mr Walter Kirman in the laboratory of the Royal College of Science, South Kensington, and an account of their experiments was given at the opening meeting of the Chemical Society, held last Thursday evening When liquid hydrogen fluoride is brought into contact with sulphur trioxide a violent reaction occurs The product of this reaction, provided any great rise of temperature is prevented by extraneous cooling, is now shown to be fluorsulphonic acid, a liquid behaving in many respects like the chlorosulphonic acid, $SO_2(OH)Cl$, discovered by Prof Williamson The preparation of fluorsulphonic acid was effected in the following manner —A quantity of sulphur trioxide was first distilled from a glass apparatus into the receiver of a distillation apparatus constructed entirely of platinum A quantity of the anhydrous double fluoride of hydrogen and potassium, HF KF, more than sufficient to furnish enough hydrogen fluoride to combine with all the sulphur trioxide, was then placed in the retort of the latter apparatus, and the retort connected with a long condensing tube surrounded by a freezing mixture of ice and crystallized calcium chloride. The receiver containing the sulphur trioxide was finally adjusted to the condensing tube, and was likewise surrounded by a similar freezing mixture. Upon heating the retort the double fluoride of hydrogen and potassium was dissociated, and pure hydrogen fluoride (hydrofluoric acid) distilled over into the receiver and reacted with the sulphur trioxide The excess of hydrogen fluoride was subsequently removed by means of a current of dry carbon dioxide, the receiver and its contents being warmed to a temperature of about 30° during the process The fluorsulphonic acid thus prepared is a colourless mobile liquid, which possesses an extraordinary affinity for water, reacting, in fact, with that liquid with almost explosive violence It fumes when exposed to air, and possesses a specific mildly pungent odour quite different from that of hydrofluoric acid It may be distilled, with but slight decomposition, in a platinum apparatus, its boiling point (corrected) being 162°·6 The latter constant was determined by use of a specially constructed platinum distillation apparatus, in the neck of the retort of which was fitted a small platinum tube containing a little mercury, and in which the thermometer was immersed during the process of distillation, in order to protect it from the powerfully corrosive action of the vapour The error introduced by the use of this arrangement was very slight, and was determined by distilling liquids of known boiling points Considerable interest is attached to the relatively high boiling point of fluorsulphonic acid, inasmuch as it is several degrees higher than that of chlorosulphonic acid, which boils at 155°·3 It would appear as if this fact is in some way connected with the relatively high boiling point of hydrogen fluoride itself (19°), as compared with that of hydrogen chloride, which, as most people are aware, is gaseous down to comparatively low temperatures The main products of the decomposition which occurs to a slight extent during distillation, are most probably sulphuric acid and sulphuryl difluoride, SO_2F_2, which latter compound Prof. Thorpe and Mr. Kirman shortly hope to isolate by a method similar to that by which Behrend prepared the analogous sulphuryl dichloride, SO_2Cl_2.

THE additions to the Zoological Society's Gardens during the past week include two Maholi Galagos (*Galago maholi*) from South Africa, presented by Mr Luscombe Searelle, a Feline Genet (*Genetta felina*), a White-eared Scops Owl (*Scops leucotis*), a Tawny Eagle (*Aquila naevioides*) from Matabeland, South

Africa, presented by Mr. B B. Weil, two Jackdaws (*Corvus monedula*, white var) British, presented by Mr Harding Cox, F Z S, eighteen Deadly Snakes (*Trigonocephalus atrox*) from Demerara, presented by Mr J J Quelch, C M Z S; a Common Chameleon (*Chamæleon vulgaris*) from North Africa, presented by Mr J Pettitt, a Blue and Yellow Macaw (*Ara ararauna*) from South America, deposited, four Lapland Buntings (*Calcarius lapponicus*), twelve Snow Buntings (*Plectrophanes nivalis*) European, six Cirl Buntings (*Emberiza cirlus*) British, purchased

OUR ASTRONOMICAL COLUMN

THE NEW COMET — The following observations of the "Comet Holmes" are communicated to the *Comptes rendus* by M Bigourdan, Paris Observatory —

Date	Paris Mean Time h m s	App R A h m s	App Decl ° ′ ″
Nov 9	7 59 25	0 45 55 51	+ 38 19 25 8

13	11 25 6	0 44 2 33	+ 37 52 48 6

On November 9 the comet was a large and bright nebulosity, perfectly round, and 5′ 5 in diameter It showed a central diffused nucleus, 10″ in diameter A rather brighter portion of an approximately elliptic form appeared to extend from the nucleus in the direction $p = 127°$, its axes being 1′ 5 and 30″ respectively On November 13 the comet was only seen intermittently It was 8′ in diameter and nearly round The nucleus no longer occupied the centre, but had shifted towards the preceding portion The elliptical region was 2′ by 30″, and in the direction $p = 116° 8$ To the naked eye it was easily visible, being as bright as the Andromeda nebula near it, but less easily distinguished, owing to its smaller apparent size.

The most recent elements and ephemeris have been obtained from observations made on November 9 at Karlsruhe, November 10 at Rome, and November 11 at Gottingen, and are given in *Astronomische Nachrichten*, No 3128, from which we make the following extract —

Elements

The comet can be easily picked up with a small telescope by knowing that it lies in a line joining the stars β and θ Andromedæ, about one-third of the distance from β

MOTION IN THE LINE OF SIGHT — The transformation of the great reflector of the Paris Observatory for the purpose of adapting it to the spectroscopic determination of radial velocities is described by M H. Deslandres (*Comptes rendus* 20) Instead of having a flat mirror at 45°, a collimator was placed in the optic axis itself, and movable along it. The rest of the spectroscope, which contained three flint prisms and a camera, was enclosed in a rigid steel box attached to the upper ring of the telescope. In order to control the motion, the plates forming the slit were made of polished steel and slightly inclined, so as to throw an image of the sky down into an auxiliary telescope inside the tube, which was provided with a reflecting eye-piece. Thus the observer below, standing near the great mirror, was enabled to keep the star well on the slit. With this arrangement, spectra of stars down to the 4th magnitude could be obtained, 12 cm long, in two hours. In the blue portion a displacement of 0·005 mm. indicated a velocity of 3 6 km per second The lines whose displacements were measured were those of hydrogen, calcium, and iron. 250 stars are within reach of the instrument For α Aurigæ, with a comparison of 30 lines, the velocity was + 43 5 km β Aurigæ is a spectroscopic double with velocities, on February 5, of − 84 km and + 97 km. Venus, on April 12, had an actual velocity of 13 55 km That indicated by the negative was 15 km

"HIMMEL UND ERDE" FOR NOVEMBER — The current number of *Himmel und Erde* contains many astronomical articles of interest "The Heat in August, 1892" is the subject of an article by Prof W J van Bebber In this he brings together all the statistics of the temperature readings during the interval between August 11 and 25, and shows by weather charts the general state of the weather, such as wind, barometer, &c The following few values, showing the highest temperatures recorded and extracted from the table mentioned above, may be of interest —

Dr J Scheiner, on "Astronomy of the Invisible," deals with the discovery of the dark companions of Sirius and Procyon. He commences with an historical sketch of the study of the proper motions of the fixed stars and leads up to the most modern observations describing the results obtained with regard to Sirius and Procyon Prof Barnard, with the help of two excellent woodcuts, explains the working of the great Lick refractor To prepare the instrument for micrometric work, he says five minutes is required, but for photographic work ten minutes is necessary, as a photographic correcting lens has to be adjusted to compensate for the difference between the photographic and optical focus, the large spectroscope absorbs nearly half an hour's work before it is ready for observation

OBSERVATIONS OF PERSEIDS — During the August display of the Perseids it has been noticed that in addition to the principal radiant point several minor ones have been observed, which although not very far distant from the primary one, are still far enough to suggest that they belong to another swarm of particles following a different track in space The orbit, which the particles in the main follow, corresponds, as is well known, to that of the comet of 1862 III, and M Bredikhine has suggested that the particles producing these minor radiant points belong really to the same swarm, only have either been acted on by external forces such as the perturbations of the major planets, or have been projected from the comet itself at different periods

With the intention of bringing some facts to bear upon this idea, M Puiseux, in the *Bulletin Astronomique* for October, gives the results of his observations made in August of last year, which seem to confirm those of M Bredikhine in several points of view.

His method of observation was simply to chart down on a large celestial globe the positions of the trails as observed A glance at this globe, after 199 positions had been so recorded, indicated that the area of radiation occupied a considerable surface, and extended principally in the directions of right ascensions, that several distinct centres of concentration were observable, and that the same radiant points, in general, manifested their activity at the same time, *i e*, on the evenings of August 10, 11, and 12, and some on August 7. In the table accompanying this paper M Puiseux shows that no less than fourteen different centres of radiation were observed. Table II, which we produce here, contains the essence of the whole work, and shows the positions of the radiant points in question, together with the corresponding elements of the orbits deduced. It must be remembered of course that their values cannot be very accurate, owing to the difficulty of observation, but the results are nevertheless interesting. The different radiant points are denoted by A, B, C, &c., while α and δ represent

their right ascension and declinations, the other nomenclature is that usually adopted in cometary computations

GEOGRAPHICAL NOTES

THE Royal Geographical Society has determined on a change in the form and alteration in the title of its *Proceedings*, which will materially enhance the value of the monthly publication The size of each part will be increased to ninety six pages, and two volumes will be published in the year instead of one as formerly Internally the arrangement will be slightly altered, and while the strictly geographical character of the publication will be maintained, the notes and record of geographical work from other countries will be made at once more systematic and more popular A special feature will be the record of the "Geographical Literature" of the month, summarizing all the accessions to the library, both books and memoirs This will form a subject-index to geographical literature, and serve as a continuous appendix to the exhaustive subject catalogue of the Society's library which is now being compiled The editorship of the new series remains in the hands of Mr J Scott Keltie, the assistant secretary

WITH reference to the note on the death of Lieutenant Schwatka, the Alaskan explorer, published last week, we are glad to observe that an official enquiry negatived the theory of suicide, and showed that the fatal result followed from an overdose of morphia taken medicinally.

THE German colonial authorities have recently come to a very important decision as to the official spelling of the place names of their various protectorates in Africa and New Guinea European names are to retain their ordinary form, but all native names are to be rendered phonetically according to a new set of rules These rules so closely resemble those put forward by the Royal Geographical Society, and now widely used, that it appears possible by some slight concessions on both sides to make one set serve both for English and German The letters *c*, *q*, *x*, and *z* are dispensed with as redundant, *c* and *z* being rendered by *ts*, *x* by *ks*, and *q* by *kw* The gutteral *ch* becomes *kh*, the English *ch* being given as *tsh*, and the sound of the English *j* as *dj* The German *j* sound will be represented by *y*, and the letter *j* used only for the French sound, which is represented in English as *zh* The German sound of *w* is rendered as *v*, the letter *w* being kept for the English sound Unfortunately the letter *s* is kept for its soft German sound, the sharp sound of the English letter being shown by *ß* The use of the English *z* would have overcome this difficulty, and removed the most serious obstacle to a common orthography

CAPTAIN MONTEIL, whose arrival at Kano on his way to Lake Chad was referred to in May last (vol xlvi p 110), has at last been heard of, and his mission, although involving two years of travel in the Sudan and Sahara, appears to be successfully completed The facts could not be put more concisely than in Monteil's official telegram to the French Foreign Office, which arrived on November 15 —"October 17 To-day I entered the territory of Fezzan by way of Tejerri coming from Kuka. Having set out from Kano on February 19, I reached Kuka on April 10, where the reception was excellent. I left Kuka on August 15 with a guide, sent by the Sheikh to accompany me to Murzuk . which I expect to reach on or about the 25th, and to stay there just long enough to arrange my departure for Tripoli. Badaire has borne the journey exceedingly well My men are all with me, except two left at Kuka" This is the most important journey through the Central Sudan and Sahara since the classical explorations of Barth and Rohlfs

STROMBOLI IN 1891 [1]

STROMBOLI is one of the most noted but least studied of volcanoes The regularity of the weak explosions which, succeeding each other at intervals of a few minutes, characterize its normal state, gives rise to the idea that its action is always thus uniform and monotonous, and the occasional paroxysms to which it is subject are apt to be overlooked In reality the so-called Strombolian phase of volcanic activity differs from the Plinian phase exhibited by Vesuvius and certain other volcanoes merely by the absence of intervals of perfect repose between the violent outbursts which are characteristic of the latter type It is in this difference that the explanation of the fact is to be found, that from time immemorial no explosion in any way comparable to the great explosions of Vesuvius have occurred at Stromboli, for the ceaseless activity of the latter prevents the accumulation of sufficient force to produce a powerful and destructive effect But from time to time the throat of the volcano does get more or less choked, and the efforts of the imprisoned vapour to escape result in an eruptive phase of some violence Such an event took place during the latter months of last year, and the following description of the phenomena is based on the observations of Profs Ricco and Mercalli, and of Ing Arcidiacono

The state of the volcano preceding this outburst had been one of relative calm for two years In October, 1888, an explosion had opened three new mouths on the upper edge of the Sciara del Fuoco, from one of which lava was emitted This was the commencement of a period of increased activity, with repeated issue of lava, lasting nine months till June, 1889 From this date to the eruption of last year, and particularly during the six months just preceding, the activity was less than normal It is to be noticed, however, that there were two short intervals of recrudescence, lasting only a few days, at the end of December, 1890, and January, 1891

On June 24, 1891, at 12 45 p m, two strong earthquake shocks were felt over the whole island at an interval of a few seconds Loud rumblings and a violent explosion followed each The shocks were not confined to the island of Stromboli, but were felt at Salina, a distance of 40 kilometres Even the subterranean rumblings were heard at the latter island The first shock and the first explosion were, as might be expected, more violent than any which succeeded Windows were broken at the semaphore station, and a great precipice of rock fell into the sea at the Filo del Cane, and other rocks in the same locality were so loosened that they fell on following days. Two powerful columns of ash, like thick smoke, arose from the crater and ascended far above the summit of the island Great masses of scoria were ejected and fell toward the northern part of the island, burning the grass and fig trees A boat passing to the north-east of the island at the time of the first explosion could not see the semaphore signals, owing to the quantity of ash in the atmosphere Lapilli fell around the eruptive mouths for a radius of a kilometre and a half, and a fine, dark grey ash rained over the whole island A stream of lava issued from a point on the Sciara del Fuoco near to the most western mouth, and a deep fissure formed its upper rim nearly in the same place as that of November, 1882. For two days the lava continued to flow, and loud explosions were frequent The rumblings were almost continuous On the 26th the emission of ash ceased, but moderately vigorous outbursts occurred with the ejection of incandescent scoria till the 27th, but on the 28th and 29th the volcano had resumed its wonted calm On the 30th, however, a fresh earthquake, accompanied by rumblings and a violent explosion, showed that the volcanic forces were not yet spent. An immense column of vapour and incandescent materials arose from a new breach on the edge of the Sciara, while an abundant current of lava flowed down the slope reaching the sea at its foot The whole of the powerful explosions o the 30th were repeated at short intervals, but the activity

[1] Sopra il Periodo eruttivo dello Stromboli cominciato il 24 giugno, 1891. Relazione dei Prof A. Riccò e G Mercalli col Appendice dell' Ingegnere Arcidiacono ("Annali dell Ufficio Centrale Meteorologico e Geodinamico" (2) XI Pt. 3, 1892)

gradually declined till July 4, when its normal state was reached. The eruptions were again violent, with emission of lava from the 16th to the 23rd of July.

The mouths on the edge of the Sciara, which were contemporaneously active during the above period, were four in number—two at the northern end and two at the western end. One of the former pair was opened by the explosion of June 30, and from it was ejected the greater part of the detrital material of the eruption, so that around it a cone has been built up, truncated by a crater, sub-elliptic in form, of about 60 metres in maximum diameter. The height of this new cone above the old edge of the Sciara is about 50 metres. The other crater is situated on the deep fissure mentioned above, and at night, from the sea the incandescent lava could be seen in free communication with the atmosphere—a circumstance which explains the fact that the explosions from this crater were rare and of feeble intensity. The two western ones were situated one below the other with an interval of about 30 metres. Near the lowest, three large fumaroles gave forth dense columns of steam, while other lesser fumaroles were plentifully scattered about. The majority of the explosions took place from these two mouths. During this same period, lava was emitted three times, (1) on June 24, soon after the first two explosions from the most western part of the Sciara, (2) on June 30, from the crater on the fissure, (3) on July 16, from the central part of the Sciara, between the first two. They all reached the sea, and since the second stream doubled itself round an obstacle about half way in its course, four new points were formed on the shore. The thickness of the lava at these points varied from 4 to 6 metres. Specimens of the lava collected from the most western stream showed that it consisted of an almost homogeneous blackish brown paste, compact in the interior, but becoming more and more porous and reddish in colour towards the exterior. Some of the larger cavities were internally covered with a shining brown patina. Externally it was covered with a rough crust, reddish-brown in colour, and of scoriaceous aspect. It was sensibly attracted by the magnet, and melted without effervescence to a brownish-green glass. Crystals of plagioclase, augite and olivine were apparent. In section, about two-thirds was rendered opaque and black by very minute microlitic granules of magnetite which were intimately mixed with a transparent glassy base, colourless or inclining to greenish. The remaining third consisted of a great number of colourless transparent microlites of plagioclase. Fluidal structure was only just apparent. In this microlitic paste were scattered crystals of plagioclase, augite, and olivine. The augites were greenish in section and possessed a feeble pleochroism. The olivines were corroded and irregularly fractured.

Analysis gave the following numbers —

	Stromboli	Etna Mean of analyses of 20 modern lavas
Silica	50.71	49.45
Alumina	13.99	19.30
Ferric oxide	5.13	11.82
Ferrous oxide	9.10	
Manganous oxide	.42	—
Lime	10.81	10.21
Magnesia	4.06	3.69
Potash	3.02	1.33
Soda	2.87	3.58
Loss on ignition	.24	—
Cl and SO_3	(traces)	—
	100.35	99.38

The lava is similar to other lavas of Stromboli, and to show the great similarity between the lavas of Stromboli and Etna, the mean of the numbers of twenty analyses of modern Etna lavas is appended for comparison.

The scoria, lapilli, and ash of the eruption present no special features, but are what might be expected from a lava of the above composition.

Although the volcano had reached a state of comparative calm at the end of July, this did not last for very long. Towards the end of August fresh signs of activity gave warning of an approaching explosion, which took place on August 31. It was preceded by an earthquake a few seconds before, and as a result a vast column of ash rose above the volcano, while scoria and other projectiles were shot out to a considerable distance. Soon after, a fine ash, dark red in colour (instead of black as in June–July), fell over the island, covering the ground in some places to a depth of several centimetres. On the evening of September 1 dense columns of ash were again emitted, and in the afternoon of September 3 the whole crater was enveloped in a thick mantle of steam, in the midst of which could be dimly seen a reddish-grey column of ash rising with extraordinary violence to a great height, when it spread out into a volcanic "pine." A fresh stream of lava was also observed. Eruptions succeeded each other at short intervals, accompanied by continuous rumblings, interrupted now and again by loud explosions, like heavy artillery. As far as could be observed, on the western side of the crater was a single mouth of almost circular form, 10 metres in diameter, which was most active in sending up vast columns of ash and projectiles of all kinds. To the east could be seen one or more little mouths, which tranquilly emitted large volumes of steam, while in the midst a large aperture, 30 metres in diameter, irregular in form and deeply fissured, was in powerful action. The activity, however, gradually quieted down, and towards the end of the year the volcano resumed its normal state.

In conclusion, it is useful to compare this eruptive phase of Stromboli with other contemporaneous seismo-volcanic phenomena of the Italian peninsula. It appears that earthquakes occurred in various districts in the early months of 1891, especially one on June 7 in the Verona district, rather severe, occasioning loss of life. Vesuvius was rather more active than usual during the whole of June, and in correspondence with this the great fumarole of the solfatara at Pozzuoli, increased in temperature. It is particularly interesting to note that Vulcano, the other active volcano of the Lipari Islands, remained in perfect calm during the whole period, emitting only vapour from the fumaroles. As, however, the character of the eruptions and the lithological composition of the material ejected from this volcano differ so greatly from those of Stromboli, it is tolerably certain that there is no free and direct communication between the reservoirs of these two volcanoes. In fact, Stromboli presents a much greater analogy with Etna. The similarity of the lithological composition of the lavas of these two volcanoes has already been referred to, and, further, Prof. Mercalli observes that the last four or five eruptions of Etna have all been immediately preceded or followed by a paroxysm at Stromboli. It is thus possible that there is a real relation between them.

L. W. FULCHER.

A LARGE METEORITE FROM WESTERN AUSTRALIA.

IN the *Mineralogical Magazine and Journal of the Mineralogical Society* of July, 1887 (vol. vii.) Mr. L. Fletcher, M.A., F.R.S., president of the Society, describes four specimens of a new meteoric iron found at Youndegin in Western Australia. They were discovered about three quarters of a mile to the north west from the top of Penkarring Rock, in the above district, about seventy miles from York. These fragments were found by Alfred Eaton, a mounted police constable, when on duty in the district of Youndegin, when he brought in one of the four pieces he found on January 5, 1884. Mr. Fletcher states that the late Mr. Edward T. Hardman, F.G.S., the then Government geologist, expressed his belief in the meteoric origin of these iron masses. Later the above-named Alfred Eaton was sent with a native assistant with instructions to bring in the other three pieces, and at the same time an unsuccessful search was made for additional fragments. In the above account it is stated that the four pieces were lying loose on the surface, three of them close together, and the fourth fifteen feet away. They weighed respectively 25¾ lbs., 24 lbs., 17½ lbs., and 6 lbs., the largest and smallest fragments are now in the British Museum collection, and the specimen of 24 lbs. is in the Geological Museum at Freemantle, and the fourth piece, weighing 17½ lbs., was presented to the Melbourne Museum in Victoria.

The new specimen now in my possession was discovered last year, and weighs 382½ lbs., and measures 22¾ inches high, 20½ inches wide, and 13¼ inches in its greatest thickness. In form it is roughly convex on one side and concave on the other, on both sides of which are large depressions or pittings similar to those usually observed on other large masses of meteoric iron. It is somewhat triangular in outline, but with irregular sides. It has one small hole quite through the mass near the top, and numerous deep holes, one near the bottom left hand corner

having a diameter of about 1½ inches and 4 inches deep, another at the opposite bottom corner 2 inches deep and 2 inches in diameter, also another of 3 inches deep, and several others On the upper edge especially, and at several other parts near, also on the edges, are fractured surfaces, as if in its fall a mass or masses were broken off, leaving a coarse crystalline structure, and which would indicate that several other large holes having existed before its fall on the earth, probably all or most of the pieces were connected together, and might have fallen in one mass It would be interesting to know if any of the pieces fitted together at the fractured surfaces as seems to me might be detach a fragment of which the cut face was not 2½ inche square

Mr Fletcher also states that on treating a specimen of this Youndegin iron to the action of bromine water, or of dilute nitric acid, the polished section gave no definite figures, but assumed a damascened appearance very like the Tucuman iron and of that of Brazos, being very similar to the latter in the proportion and distribution of the Schreibersite, some specimens of the Arva, the Sarepta, and the recently found Canon Diablo are similar as exhibiting these characters

One fifth natural size

possible. I observe that the two specimens of this iron in the British Museum collection exhibit similar fractures on the edges Before receiving this specimen I was informed that two masses were found, but have no information at present as to the size and weight of the other.

Mr. Fletcher in his paper minutely describes the size and form of the two British Museum specimens, and that the specific quantity was determined from three small pieces from the larger specimen, and gave 7·86, 7·85, and 7·72. He also states that a portion was cut off the larger piece by means of hack-saws, and was found to be so hard that three weeks were required to

The Youndegin Iron was also remarkable in containing the minute cubic and modified cubic crystals, having metallic lustre and of a greyish black colour, and which were determined to be graphitic in character, but of a diamond-like form, but were later found to be still distinct from the diamond, but having somewhat more the features of graphite. Mr Fletcher therefore decided to give the name of Cliftonite to this substance, as being a new form of a carbon mineral A most exhaustive description of this new mineral is given in his paper. Similar crystals of this substance are found in one or two other meteoric irons.

The composition of the Youndegin iron was found to be as follows —

Iron	92 67
Nickel	6 46
Cobalt	0 55
Copper	trace
Magnesium	0 42
Phosphorus	0 24
Sulphur	none
Insoluble cubes	0 04
	100 38

JAMES R GREGORY

THE CROSS-STRIPING OF MUSCLE

PROF RICHARD EWALD of Strassburg, has just communicated a paper to the fifty second volume of the *Archiv f. d ges Physiol*, in which he confirms Prof Haycraft's views concerning the structure of striped muscle The latter observer has held for many years that muscle fibrils are varicose threads, and that the cross striping is but an optical appearance due to this varicosity The varicosity is often difficult to demonstrate in the ordinary way, and most histologists were not prepared to admit that the stripings are all and entirely due to it Prof Haycraft, however, recently brought forward to the Royal Society of London, and to the Berlin International Medical Congress, fresh and striking proof of the strength of his position, by demonstrating films of moist collodion, on which pieces of muscle had been pressed and then withdrawn As a result of this pressure the collodion films were stamped as with a seal, and the impressions revealed in striking detail every stripe of the original fibre Prof Ewald confirms these experiments in the fullest manner, but suggests that the collodion impressions might be produced on the assumption that there are layers of hard and soft material alternating with each other in the course of the fibrils In this case the hard material would press into the collodion and make a series of furrows, which would appear as a series of stripes when examined with the microscope Prof Haycraft had previously demonstrated the varicosity of the fibrils, seen by transmitted light, and had published photographs of his preparations, but Prof Ewald was still sceptical upon this particular point, and sought to assure himself still more conclusively With this end in view he examined muscle, which had been rendered quite opaque, by means of reflected light, for under these circumstances the influence of the internal structure would be entirely set on one side, and the surface of the fibrils would alone receive and reflect the illuminating rays For purposes of illumination Prof. Ewald used the apparatus of W and H Seibert, of Wetzler, by means of which vertical rays can be projected upon an opaque object; and he rendered his preparations, both of fresh and of hardened muscle, quite opaque by a method of over-silvering Under these conditions Prof Ewald found that the cross-striping is most distinct, and he was able, with his admirable method of illumination, to examine the surface of a muscle just as one may observe the surface of the country at night by means of a search light from an observatory. With the light perfectly vertical the tops of the ridges of the muscle are bright, and the valleys on either side in half-light By shifting the light to one side or to another the slopes of the ridges can be thrown alternately into shadow or bright light. Prof Ewald concludes by admitting that his experiments fully prove that the striping is due to the shape of the fibrils alone, and that the internal structure of the muscle plays no part in its production

IRIDESCENT COLOURS [1]

ON taking a general survey of coloured objects, whether natural or artificial, we become aware of the fact that whilst the colours of some remain unchanged as regards tint, whatever their position in relation to the incident light, the tint of others varies with every alteration in their relationship to such light source We thus see that so far as their colours are concerned all bodies may be arranged in two groups according as their colours change or do not change in tint as their angular relationship to the light varies Nor is this classification entirely an artificial one, since, as will shortly be seen, though this change in tint with variation in the light source is an essential difference, it is not the only difference, even in the colour manifestations of the two groups, for it is also characteristic of the nature of the colour producing structure It is to the above mentioned varying colours that we apply the term iridescent, from the resemblance they have in the sequence or play of colours to the tints of the rainbow The unvarying group of colours, having no equivalent term to "iridescence" to express the nature of their colour production, are spoken of as "pigmentary," or absorption colours In naming examples of objects, natural and artificial, grouped as above in accordance with the nature of their colours, it is difficult to make a selection where all are so varied and characteristic I have preferred therefore to cite only such instances as I myself possess, and am therefore able to show you As examples of pigmentary colours, I need only name one or two for the sake of comparison, since the colours of most objects ordinarily met with are pigmentary Leaves, flowers, dyes, birds, fish, insects, minerals, &c, exhibit these colours, some almost entirely, and all, excepting fish, in far the majority of instances Of objects displaying iridescent colours we have also examples in the various divisions of the animal, vegetable, and mineral kingdoms Amongst birds the most striking examples are found amongst the humming birds, sun birds, birds of paradise, &c. Insects, again, furnish numerous examples, more especially amongst tropical species, though not, perhaps proportionally in greater numbers than amongst those belonging to our own more temperate regions The colours of fish are almost entirely iridescent, since their very whiteness, or silvery sheen, is due to the admixture of the iridescent colours of innumerable minute thin lamellæ, too small to be seen individually with the naked eye, but plainly perceptible under the microscope In the vegetable kingdom iridescent colours are far more numerous than is ordinarily recognized, since the surfaces of the cell walls produce interference colours which are more or less obscured by the pigmentary colours of leaves and coloured flowers, but may be readily seen in the case of white flowers by the aid of a lens and sunlight Under these conditions each cell may be seen to sparkle with its own iridescent colour, forming, by admixture of the interference tints of neighbouring cells, the varying shades of white seen in numerous flowers which are devoid of pigmentary colour Mineral bodies displaying iridescent colours are also numerous, opals, sunstone, fire marble, felspar, mica films, tarnish on various metallic crystals, certain crystals of chlorate of potash, &c., are examples

In describing the various natural objects for purposes of identification, or mere description, no account can be considered complete which omits all reference to their colours, and more especially is this the case where the colours constitute such a striking feature, as in the case of iridescent bodies. In innumerable instances, more especially amongst birds and insects, their specific names are taken from some conspicuous colour they possess. It thus becomes evident that a correct description of the colours of bodies is of importance, and where these colours are of the pigmentary, or unchanging kind, this is a matter of no difficulty How different, however, in the case of objects, the colours of which not only vary with every change of position, but disappear altogether, unless viewed with special relation to the light source Nor can it be wondered at that descriptions of these objects, even by observers of undoubted repute, vary according to the different angles from which they have been viewed, or are vague and profuse, owing to fruitless attempts to describe their changing tints produced by every movement The fact is, no words can convey an adequate impression of the gorgeous effects produced by most of such objects, whether birds, insects, or fish, when in motion in brilliant sunshine Some notion of the difficulties to contend with in describing the colours of humming birds, for example, may be gathered from the remarks of Wallace in his work on "Tropical Nature," when speaking of humming birds:—"In some species they must be looked at from above, in others from below, in some from the front, in others from behind, in order to catch the full glow of the metallic lustre, hence, when the birds are seen in their native haunts, the colours come and go and change with their motion, so as to produce a startling and

[1] By Alex. Hodgkinson, M.B., B Sc. Reprinted from the fifth volume of the fourth series of "Memoirs and Proceedings of the Manchester Literary and Philosophical Society" Session 1891-92.

beautiful effect." Most observers, in describing the colours of iridescent bodies, do so by attempting to depict the varied effects produced by casually changing the position of the object in relation to the light, omitting to mention the exact *sequence* of the play of colours, or the relation of these colours to the direction of the iridescent light, *i.e.*, whether produced by perpendicular or oblique illumination. Here is a description of the tufted neck humming bird, *Trochilus ornatus*, taken haphazard from a well known work:—"The throat is of a fine green colour, variable in different lights to a golden hue with a yellow or brown metallic lustre, and below that the whole of the belly is a rich brown, glossed with green, and golden." Such descriptions as the above, which happen to be the first I met with in seeking for an instance, are vague, and fail to give a definite idea of the appearance of the object. But vagueness in the description of these objects is not the only result of the changing character of their colours. As might be expected, where such variation in appearance exists, the descriptions of different authors are almost as variable as the colours. Few attempt descriptions without acknowledging the hopelessness of the task. Thus Jardine, after describing this humming bird, *Chryslampis mosquitus*, remarks:—"It is impossible to convey by words the idea of these tints, and having mentioned those substances to which they approach nearest, imagination must be left to conceive the rest." And I adduce this quotation as fairly expressing the feeling of naturalists in reference to the description of iridescent objects generally. Recognizing the admitted inability of observers to convey by description an idea of the appearance of these iridescent objects, and having myself, for many years, constantly experienced the same difficulty, I have been led to adopt a method for the examination of such objects, which, whilst extremely simple and available in its application, yields unvarying results with different observers, results, moreover, which admit of the simplest description.

Before describing this method, I may say that long experience in the examination of iridescent objects has proved to me that, almost without exception, the colours of natural iridescent objects are due to interference produced by thin plates. In order, therefore, to render clear the principles on which the method I propose is founded, I will briefly refer to certain fundamental facts in connection with colour production by thin plates, and for this purpose will select a thin film of mica, which with light at perpendicular incidence, appears red, iridescent red. If, now, this plate be inclined so that the light falls on it at a more oblique angle, it is, of course, reflected at the same angle, and now appears orange, and if the plate be still further inclined, the reflected light appears yellow, then yellowish green, green, and bluish green, and if the light were not too copiously reflected from the first surface to allow of perceptible interference by further inclination of the plate, all the colours of the spectrum in their proper sequence might be observed. The same results, but much more vividly, may be seen in these crystals of chlorate of potash. Thus, we see that by rendering the incident light more and more oblique, the reflected light changes from a lower to a higher tint, that is, from the red towards the violet end of the spectrum. And this is what occurs in the case of all iridescent bodies, as the incident light becomes more oblique the colour changes to the tint above it in the spectral order, so that, if we know what colour any such object appears when seen at a certain angle, we can infer what colour it will change to on varying the incidence. This beetle (*Sagra purpurea*), for instance, is red at perpendicular incidence, it will, therefore, appear orange yellow and green when examined by successively increased obliquity of light. And the same is true of all other iridescent red objects. If the object at perpendicular incidence be green, as in the case of this beetle (*Buprestis*), it will become blue and then violet as the incidence is increased. We thus see that an iridescent object varies in colour, simply because it is examined by light incident, and therefore reflected, at different angles. Thus, different observers see the same iridescent object of a different colour, when they view it illuminated by light at a different angle of incidence. If, however, the object is seen by all at the same angle of the incident light it will present the same colour, and this is, in fact, what the method I propose ensures, *i.e.*, that iridescent objects shall always be seen by light at one and the same angle of incidence. The angle I select is one of 90, so that the incidence and reflection are normal or perpendicular to the reflecting surface. By selecting this angle all trouble of measuring angles is avoided, since we know that the incidence is perpendicular when it coincides with reflection. Now, the reflected light may be made to coincide with the incident light by reflecting it on to the object by means of a mirror, and so adjusting the object that the light reflected from it passes to the eye through a perforation in the mirror. When examined in this way iridescent objects are marvellously altered in appearance, their changing colours are replaced by one fixed tint, visible only in one position, a fact which serves at once to distinguish them from bodies coloured by absorption, which remain coloured whatever the relation to the incident light. Such methods of examining bodies scarcely takes more time than by the eye alone. The mirror may be attached to a spectacle frame so as to leave both hands free, such as the one I show, or may be a simple hand mirror. For objects too small to be seen by the unaided eye, I have so arranged the microscope that light is made to pass down the tube of the instrument, through the object glass on to the objects, and by a special arrangement, so adjusted the position of the object that the light is reflected back again through the instrument to the eye. The method is thus available for macroscopic as well as microscopic objects.

To illustrate the practical value of this plan of examination, I have here a few objects exhibiting iridescent colours, which, by trial, will be found to give the following results:—

The crest of this humming bird, *Chrysolampis mosquitus*, which, to the unaided eye, appears resplendent with all shades of red, orange, yellow, or green, according to the angle of the incident light, appears, when examined by the mirror, of one unvarying red tint, disappearing when the object is moved but absolutely unchanging in tint. Such an object, therefore, I should describe as "iridescent red", all else regarding its colour may be inferred. Again, the breast, or gorget, of the same bird reflects all shades of orange, yellow, or green to the eye alone; with the mirror it is seen of a deep orange, which, as before, is unchanged in tints by any variation in position. Such an object I would describe as "iridescent orange." The gorget of another humming bird, *Calliphlox amethystina*, to the eye alone appears crimson, orange, yellow, or green; with the mirror it is iridescent crimson only, spectroscopically a red of the 2nd order. Amongst insects, instances of iridescent species are numberless, the results of examination are just the same as in other iridescent bodies. This butterfly, *Morpho*, to the eye alone appears either greenish blue, blue, or violet, as its inclination to the light varies; examined with the mirror it appears green, and should be described as iridescent green, or iridescent bluish-green. This beetle, *Poropleura bacca*, appears any shade of red, yellow, or green to the eye alone; with the mirror only iridescent red. In this extraordinary beetle, *Chrysochroa fulminans*, we have all the colours of the spectrum in their natural sequence, beginning with red at the tip of the wing case, and ending with violet higher up the elytron. These colours vary in an indescribable manner when attentively examined at different angles of incident light with the eye alone; with the mirror the wing cases are seen to be coloured successively from base to tip iridescent green, yellow, orange, and red, and these tints remain unaltered by change of position of the object. This piece of *Haliotis* shell exhibits indescribable changes of colour with every movement, but the difficulty of description, though by no means removed, is immeasurably lessened by the use of the mirror. And the same with this specimen of iridescent iron ore, its colours, which vary to the unaided eye, remain unchanged when examined by the mirror. To simplify the description of iridescent objects, therefore, I would advocate the above method, and would describe the result of such examination by recording the colour observed by aid of the mirror, and prefixing the term "iridescent" to express the changing properties of the colour. Bearing in mind the unvarying nature of these changes, a far clearer idea may be formed of the appearance of these objects than from any attempted description of what is admittedly indescribable. Time and space are also economized by the omission of lengthy descriptions. The accuracy, and, therefore, the value of any description of colour, is always enhanced by mapping its spectrum; more especially is this true in the case of iridescent colours. This is easily done, and by applying such map to a spectral chart, the order of the colour, and therefore its tint, is apparent. In examining many objects, chiefly birds or insects, by means of the mirror as above described, apparent exceptions are repeatedly met with to the fact stated above, that the colour

is invariable in tint and disappears by inclination of the body Such instances are no real exceptions, but are due to the reflecting plates being curved, or having pigmentary matter beneath them, or an opalescent medium above them In this way some of the most extraordinary and beautiful colour effects it seems possible to conceive are produced

In examining objects with the perforated mirror a single light is necessary The sun is of course the best, and the electric light probably almost as good I frequently employ the lime-light, but a good paraffin lamp may be used as a substitute Ordinary gas is unsuitable The light should be placed in front of the observer, its direct rays being prevented from falling on the objects by means of a book or partition of some kind resting on the table, and of such a height that the light can be seen above it , On placing the mirror to the eye the light may be reflected from the mirror on to the object, and the latter manipulated so as to reflect the ray back through the perforation in the mirror to the eye The incidence is thus known to be normal, and the colour observed is the one to be recorded

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —The following letter has been addressed by the University of Cambridge to that of Padua, which is about to celebrate the tercentenary of Galileo s professorship —

Universitas Cantabrigiensis Universitati Patavinae S P D

Litteras vestras, viri doctissimi, GALILAEI GALILAEI Professoris vestri celeberrimi in laudem conscriptas vixdum nuper perlegeramus, cum statim in mentes nostras rediit non una Italiae regio viri tanti cum memoria in perpetuum consociata. Etenim nostro quoque e numero nonnulli urbem eius natalem plus quam semel invisimus, ubi Pisano in templo lucernam pensilem temporis intervallis aequis ultro citroque moveri adhuc iuvenis animadvertit , etiam Vallombrosae nemora pererravimus, ubi antea scholarum in umbra litteris antiquis animum puerilem imbuerat , ipsa in Roma ecclesiam illam Florentinam intravimus, ubi doctrinae suae de telluris motu veritatem fato iniquo abiurare est coactus , Florentiae denique clivos suburbanos praeterivimus, ubi provecta aetate caeli nocturni sidera solus contemplabatur, ubi extrema in senectute diei lumine orbatus cum MILTONO nostro collocutus est, ubi eodem demum in anno mortalitatem explevit, quo NEWTONUS noster lucem diei primum suspexit

SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 17 —"Stability and Instability of Viscous Liquids," by A B. Basset, F.R.S (Abstract) —The principal object of this paper is to endeavour to obtain a theoretical explanation of the instability of viscous liquids, which was experimentally studied by Professor Osborne Reynolds[1]

The experiment, which perhaps most strikingly illustrates this branch of hydrodynamics, consisted in causing water to flow from a cistern through a long circular tube, and by means of suitable appliances a fine stream of coloured liquid was made to flow down the centre of the tube along with the water. When the velocity was sufficiently small, the coloured stream showed no tendency to mix with the water, but when the velocity was increased, it was found that as soon as it had attained a certain critical value, the coloured stream broke off at a certain point of the tube and began to mix with the water, thus showing that the motion was unstable It was also found that as the velocity was still further increased the point at which instability commenced gradually moved up the tube towards the end at which the water was flowing in

Professor Reynolds concluded that the critical velocity W was determined by the equation

$$Wa\rho/\mu < n,$$

where a is the radius of the tube, ρ the density, and μ the viscosity of the liquid, and n a number ; but the results of this

[1] *Phil. Trans.* 1883, p. 935.

paper show that this formula is incomplete, inasmuch as it does not take any account of the friction of the liquid against the sides of the tube

In the first place, if the surface friction is supposed to be zero, so that perfect slipping takes place, the motion is stable for all velocities If ϵ^{kt} be the time factor of a disturbance of wave-length λ, the value of k is

$$k = -\frac{2i\pi W}{\lambda} - \frac{\mu}{\rho a^2}\left(\frac{4\pi^2 a^2}{\lambda^2} + n^2\right) \qquad (1),$$

where n is a root of the equation $J_1(n) = 0$

Experiment shows that when the velocity is greater than about six inches per second, the frictional tangential stress of water in contact with a fixed or moving solid is approximately proportional to the square of the relative velocity This introduces a constant β, which may be called the coefficient of sliding friction, whose dimensions are $[ML^{-3}]$, and are therefore the same as those of a density This constant may have any positive real value, $\beta = 0$ corresponding to perfect slipping or zero tangential stress, whilst $\beta = \infty$ corresponds to no slipping, which requires that the velocity of the liquid should be the same as that of the surface with which it is in contact Owing to the intractable nature of the general equations of motion of a viscous liquid, I have been unable to obtain a complete solution, except on the hypothesis that β is an exceedingly small quantity This supposition, I fear, does not represent very accurately the actual state of fluids in contact with solid bodies, but at the same time the solution clearly shows that the instability observed by Prof Reynolds does not depend upon viscosity alone, but is due to the action of the boundary upon a *viscous* liquid

To a first approximation, the real part of k is proportional to

$$\frac{Wa\beta}{\mu} - \frac{(n^2 + m^2a^2)^2}{4n^2} \qquad (2),$$

where $2\pi/m$ is the wave-length of the disturbance, and n is a root of the equation $(J_1 n) = 0$ Since the second term is a number, this shows that the motion will be stable, provided

$$Wa\beta/\mu < \text{a number}$$

The experiments of Prof. Reynolds conclusively show that the critical velocity at which instability commences is proportional to μ/a, and the fact that the theoretical condition of stability turns out to be that Wa/μ, multiplied by a quantity of the same dimensions as a density, should be less than a certain number, appears to be in substantial agreement with his experimental results.

The results of the investigation may be summed up as follows —

(i) *The tendency to instability increases as the velocity of the liquid, the radius of the tube, and the coefficient of sliding friction increase, but diminishes as the viscosity increases*

(ii) *The tendency to instability increases as the wave-length ($2\pi/m$) of the disturbance increases*

The remainder of the paper is occupied with the discussion of a variety of problems relating to jets and wave motion.

I find that when a cylindrical jet is moving through the atmosphere, the tendency of the viscosity of the jet is always in the direction of stability. The velocity of the jet does not affect the stability unless the influence of the surrounding air is taken into account, if, however, this is done, it will be found that it gives rise to a term proportional to the product of the density of the air and the square of the velocity of the jet, whose tendency is to render the motion unstable. The tendency of surface-tension (as has been previously shown by Lord Rayleigh) is in the direction of stability or instability according as the wave-length of the disturbance is less or greater than the circumference of the jet.

If in addition, the jet is supposed to be electrified, the condition of stability contains a term proportional to the square of the charge multiplied by a certain number, n When the ratio of the circumference of the jet to the wave length is less than 0·6, n is positive, and the electrical term tends to produce stability; but when this ratio is greater than 0·6, n is negative, and the electrical term tends to produce instability. It must, however, be recollected that when the above ratio is greater than unity the tendency of surface tension is to produce stability, but if the influencing body is capable of inducing a sufficiently large charge, the electrical term (when $2\pi a > \lambda$) will neutralize the effect of surface tension and viscosity, and the motion will be unstable

The well-known calming effect of "pouring oil on troubled waters" has passed into a proverb The mathematical investigation of this phenomenon is as follows —The oil spreads over the water so as to form a very thin film, we may therefore suppose that the thickness l of the oil is so small compared with the wave-length hat powers of l higher than the first may be neglected Also, since the viscosity of olive oil in C G S units is about[1] 3 25, whilst that of water is about 0 014, the former may be treated as a highly viscous liquid, and the latter as a frictionless one

The result is as follows —

Let ρ_1, ρ be the densities of the water and oil, T_1 the surface tension between oil and water, T the surface tension between oil and air, μ the viscosity of the oil, and ϵ^{kt} the time factor, then, to a first approximation,

$$k = -\frac{\{g(\rho_1 - \rho) + T_1 m^2\}(g\rho - Tm^2)l}{4\mu\{g\rho_1 - (T - T_1)m^2\}}$$

For olive oil, $T_1 = 20{\cdot}56$, $T = 36\ 9$, so that $T > T_1$, and I find that the motion will be stable unless the wave length of the disturbance lies between about 9/11 and 6/5 of a centimetre This result satisfactorily explains the effect of oil in calming stormy water

Dr Hobson, Mr J Larmor, Mr Bateson New Members of Council Prof Thomson, Mr F Darwin, Dr Shore, Mr Ruhemann.—The retiring President addressed the Society —The following communications were made —Note on the determination of low temperatures by platinum-thermometers, by Mr E. H Griffiths and Mr G M Clark The authors, following up the suggestion of Profs Dewar and Fleming, that the resistance of certain pure metals vanishes at absolute zero, have assumed the possibility of extrapolating the platinum thermometer formulæ, and have thus found the temperature at which $R = 0$ From the previously-published constants of seven different thermometers—including Callendar's original wire—the mean value deduced by them is $-273°\ 86$, which is in remarkable agreement with Joule and Thomson's thermodynamical value $-273°\ 7$. They further suggest that the simple method of determining the resistance in ice and steam and assuming $R = 0$ when $t = -273°\ 7$ is sufficient to graduate a thermometer constructed of fairly pure wire, as they show that the errors so introduced will only amount to a fraction of a degree over the range $-273°$ to $+150°$ —Carnot's principle applied to animal and vegetable life, by Mr J Parker. The author discusses the question whether the conditions of the growth of plants are limited by the law of entropy. The assumption is made that Carnot's principle takes account only of the exchange of heat, and the temperature of the material system at which the exchange takes places, that the differential effect of solar radiation of different kinds consists in variation of the activity but not of the mechanical type of the growth The increase of available energy due to the building up of inorganic materials into a plant can then only be explained, in conformity with the second law of thermodynamics, by the aid of differences of temperature during growth: the author gives calculations to prove that the difference between day and night is amply sufficient for this purpose.—Note on the geometrical interpretation of the quaternion analysis, by Mr J. Brill

CHEMICAL LECTURE EXPERIMENTS

Chemical Lecture Experiments By G S Newth (Longmans, 1892)

"ON revient toujours," &c and the very description of a good lecture experiment to one who had for thirty years always enjoyed performing an old one, and was overjoyed in bringing out a new one, is something akin to that of the old war-horse when he scents the battle from afar And both Mr Newth's experiments and his descriptions are good, so I think that not only the novices of the profession but the old hands will read this book—the first with profit with a view to what they will do, and the second with pleasure in recollecting what they have done I was dining some years ago with the great Dumas (I don't mean either of the novelists), and after dinner we sat together on the sofa smoking our cigars, when he said to me, "I have been in many positions—professor, minister of state, and investigator—and I have seen the world from many points of view If I had to live my life again I would not leave my laboratory The greatest pleasure in my life has been original work, the second greatest that of teaching a class who appreciated what I was telling them" We all know that Dumas was a master in the art of experimental teaching, and those who have practised this art, even at a great distance from the master, will agree with him that the pleasure of giving a well-illustrated experimental lecture on chemistry is not a small one, and even that a man may go on for thirty years and yet not be altogether tired of the job The reason for this is not far to seek Our science in its daily progress constantly opens up new paths which yield matter suitable for lecture experiment, and this gives a zest to the discourse unattainable by the teachers of most other subjects Mr Newth has collected an ample store, and he has described them clearly For the collection he has had favourable opportunity, to begin with he was a distinguished student at Owens, and there he may have picked up a few wrinkles, then he has for many years been Lecture Demonstrator to Frankland and Thorpe, and from them the wrinkles he has picked up have certainly been many But although doubtless some are of his own finding out, I think it would have been well if he had added after the description of each experiment the name of the authority with whom it originated Thus some have been described by the chemists I have named, others owe their existence to Hofmann, Bunsen, and others These additions are not only due to the authors, but would add to the interest of the book. Mr Newth should see to this in the next edition The old booksellers tell us that Faraday's "Manipulations" is a work which no lecturer should be without, and as everything which that prince of experimenters wrote or did is worthy of attention, they speak truly, and yet no modern chemists can be bound by Faraday's experience of sixty years ago Things are not as they were; and the methods of work and the illustrations of chemical phenomena which he details belong to a bygone age. And so Mr. Newth comes forward to give the lecturer of to-day a helping hand The first thing that strikes one on looking through his pages, is how simple are the experiments—so far as illustrating the chemistry of the non-metals goes, and he goes no further—needed to illustrate a course of lectures. We do not require the expensive and delicate instruments of the physicist With glass and india-rubber, as Liebig said, we chemists perform all our mysteries Only in a few cases, as, for instance, when we want to hand round wine-glasses filled with liquefied oxygen or air, or when we desire to show our students free fluorine and such like things, does the apparatus become expensive or the experiments troublesome All the ordinary and many of the extraordinary experiments detailed in the book may be carried out with little cost and without great trouble, indeed most of them may be made by the veriest tyro provided he stick to the letter of the description and does not attempt to vary the proceedings, as one I knew did, who thought that as sulphuric acid is a more powerful desiccating agent than lime, he would dry his ammonia by the former substance instead of by the latter material No account of any experiment, the author tells us, has been introduced upon the authority solely of any verbal or printed description, but every experiment has been the subject of his personal investigation and the illustrations are taken from his original drawings, so that we may be sure that every experiment will "go" if properly managed and fairly dealt with Many of the experiments are, of course, old stagers, but none the less useful, whilst others are new to me and probably to most people To mention many either old or new this is not the place, but one of them, which has struck me as interesting is an easy method of showing the freezing of water by its own evaporation first with a common air-pump, and second with no air-pump at all I always used a Carre's machine, by which a quart of water could be frozen, but Mr Newth gives an excellent description of how a beautiful icicle twenty to thirty centimetres long can be obtained both with and without an air-pump The secret of how to do this can best be learnt by reading pages 57 to 59 of the book "How to float soap bubbles upon carbon dioxide" has often proved a difficult question to answer experimentally, because if you managed, after a score of trials, to free your bubble from the pipe on which you blew it, the bubble usually bursts the moment it touches your heavy gas Mr Newth lets us into the secret You must remove every trace of hydrochloric acid, which is carried over with the gas, by washing, the presence of this acid being fatal to the life of a soap bubble Under chlorine (p 88) a description is given of the mode of sealing up bulbs filled with chlorine and hydrogen This was first done in the early sixties by my old helper and friend Mr. Joseph Heywood, of Owens, to whom both students and lecturers owe many an ingenious and striking experimental illustration As Mr Newth remarks, there are many obvious reasons why the old plan of filling a soda-water bottle with a mixture of equal volumes of the gases and then throwing it out of the lecture-room window into the street, if the sun happened to shine, is "unsuitable for a lecture experiment," and Heywood's bulbs answer the purpose better in all respects. The author does not tell us—as he ought to have done—

that Victor Meyer now seals up bulbs of oxygen and hydrogen (electrolytic gas) in a similar way, and that these, like their confrères of Cl and H, can be kept not only in the dark for any time, but, unlike these, also in the light without undergoing any change. The fact that many gases when perfectly dry do not combine is illustrated by the case of chlorine and metals—brass and sodium, pp 84 and 85—as well as of carbon monoxide and oxygen, for these gases will not explode if dry, p 189 A more striking way of illustrating this latter case than that with the eudiometer is not mentioned I will add it Dry a current of carbonic oxide over glass balls moistened with strong sulphuric acid, light the stream of gas issuing from a horizontal tube, then plunge over the blue flame a cylinder full of air which has been previously dried by shaking it up with a little strong sulphuric acid The flame instantly goes out Another case of the kind observed by Arnold lends itself to a lecture experiment He found that powdered iron will not burn in pure dry oxygen, and in order to be able to estimate hydrogen in iron it was found necessary to insert a small tube containing a drop of water, through which the oxygen passed before coming into contact with the iron, this tube being of course weighed both before and after the experiment This may well be included in the next edition, which I hope will soon be called for Another capital experiment to show that iron can be carbonized by contact with a diamond was recently described to me by Mr Gilbert Fowler, of Owens. A loop of pure thin iron wire is placed in a vertical glass tube surrounded by an atmosphere of hydrogen Below the loop is a splinter diamond (or some diamond dust) placed on the top of a glass rod working through the lower end of the tube After heating the wire by a current to the highest possible temperature without fusion, bring the diamond carefully into contact with the heated iron The metal at once fuses But of good experiments "there is no end" (Mr Newth describes 620 for the non-metals alone) whilst of a review of a book in NATURE there must be a speedy end, and I will end by advising all those who like to see and to show good experiments to get Mr Newth's book

H E ROSCOE

A MANUAL OF PHOTOGRAPHY

A Manual of Photography. By A. Brothers, F R A S (London Charles Griffin and Co, 1892)

MR BROTHERS has in this well-illustrated book brought together a great amount of information relative to the history, processes, apparatus, materials, &c, which will be welcomed by all who are interested, even if only in a general way, in the fascinating art of photography The work covers about 360 pages, is divided into five parts and is accompanied by a full index.

In the short historical sketch which is introduced as the opening chapter, the author by means of quotations and otherwise gain much information which is not readily accessible, and many facts that are not inserted in our treatises, and which consequently are not generally known. At the present day, when so many possess a camera of some sort or other, it is very curious to carry ourselves back to the time of Daguerre and to picture to ourselves the idea which he put forward when he wrote in his pamphlet, "Those persons are deceived who suppose that during a journey they may avail themselves of brief intervals while the carriage slowly mounts a hill to take views of a country" Whether this is or is not the case now we will not stop to discuss, but we may mention that many other very interesting extracts are made from the same source

The next three chapters deal with the chemistry, optics, and light as applied to photography In these there seems to be nothing that calls for special attention, unless it be to state that the author has written them in a charming manner, as for instance the short summary under the heading "Magnesium Light," which one reads with quite renewed interest

Coming now to Part II, Processes, we find the most important section of the whole book. As Mr Brothers rightly observes, the old processes previous to the introduction of the gelatine bromide methods have been put completely in the shade, not because they have been surpassed by better and more trustworthy ones, but simply because they require a little more care in manipulation and consequently the consumption of more time In order to remedy this to some extent he has given great prominence to them, dedevoting nearly 140 pages to them, including working details of the more important later processes For the sake of facility of reference they are arranged in alphabetical order, and in many cases they are accompanied by illustrations which show the actual results that can be obtained by the uses of the methods under consideration To cite them in anything like detail would carry us too far away, but we may mention one or two briefly The (wet) collodion process is of course here fully described the author lays special stress on the advantage of this process, for there is no doubt that where dry plates are now used far better results could be obtained by employing this old wet process The photo-mechanical process, collotype, receives also a rather lengthy description, but its utility and the excellence of the results obtained necessarily give it some prominence A specimen illustration of the last mentioned is inserted, as well as one of a recent application of this method for printing in colour. Printing on wood, photo-lithography, platinotype, &c, together with photogravine Woodbury type and a host of others, are all described, some briefly, others of greater importance somewhat more in full

Parts III and IV deal with the apparatus and materials used in the production of a finished picture In the former the author describes the particular characteristics of many of the various kinds of cameras and accessories, while in the latter are explained the chief uses and actions of the chemicals employed

Part V., the last, contains short notices of the applications to which photography has given rise Astronomical Photography is referred to at some length, and we may mention that we have an excellent reproduction of one of Mr Rutherfurd's beautiful lunar photographs taken at first quarter. The practical

hints in the concluding chapter should be found very serviceable

Mr Brothers has produced a very serviceable and useful addition to our photographic literature; as a handbook for students it perhaps is somewhat too bulky, but nevertheless it will be very much used by them Every photographer who wishes to know something about the art with which he is working, and who does not wish to limit himself to the mere cut and-dried manipulations, should at any rate make himself acquainted with the volume. W J L

MATRICULATION CHEMISTRY

Matriculation Chemistry By Temple Orme (London Lawrence and Bullen, 1892)

THIS is still another elementary manual dealing with the non-metals and their compounds According to the author it can be studied most advantageously if the rudiments of chemistry have first been acquired The book is built on pretty much the same plan as many already in existence, here and there, however, the reading is enlivened by ideas which, if not altogether commendable, have some pretensions to novelty

The author is evidently of opinion that much of the ordinary chemical knowledge can be presented in other ways Mass and weight first receive attention In this book there are no atomic weights, atomic masses reign supreme In using a balance we are told that we do not find weights, but "only masses" Indeed to bring this idea home the following curious question is set —"When you 'weigh' a thing in an ordinary balance, do you find its weight?"

After a passing allusion to constitutional formulæ, in which they are likened to pyrotechnic frames, the next important alteration with which the author concerns himself refers to the nomenclature of oxides Such a name as sulphur dioxide or carbon dioxide is discarded, for it is "founded upon a formula which is liable at any time to be altered so as to suit our knowledge of atoms and molecules" Anhydride is described as, "etymologically at least, a still more atrocious term", hence we find that throughout the book SO_2, CO_2, &c, are spoken of as acids P_2O_5 is said to be a tribasic acid, N_2O_5 a monobasic acid CS_2 is called sulphocarbonic acid, P_2S_5 thiophosphoric acid, N_2O hyponitrous acid, and so forth, in spite of the fact that such compounds as that formed from "hydric oxide and phosphoric acid (*sic*) are often called *acids* by modern chemists"

The definition of a salt is thus summarily disposed of —"You are often asked what a salt is, the only possible answer is that it is a compound"

Such methods of tampering with terms which have a generally-accepted meaning should, it seems to us, meet with no encouragement. They can only end in muddling the reader who wishes to pursue his subject by the aid of any of our standard works But matter which is liable to do more immediate harm is frequently to be noted For instance, it is stated that there is no such thing as the Law of Multiple proportions—it is only a corollary of the atomic theory If, according to its usual interpretation, a law is a generalized statement of fact, it is rather hard to see how its existence is affected by its relations to any theory

To most chemists the brilliant work of Moissan has sufficed to settle the question of the isolation of fluorine, the author is, however, still sceptical on this point P_2O_3 is given as the formula of phosphorous acid (*sic*), recent research has shown P_4O_6 to be correct The valency of potassium is said to have been fixed by a "minute study of its *gaseous* compounds," water is stated to be elastic with regard to *shape*, and from Avrogadro's hypothesis molecules of different gases are stated to be equal in size

Even when the author is apparently trying to be precise he is apt to mislead The following definition is an example —"A chloride means a compound of chlorine with some other substance which, though it is not itself metallic in its general characteristics, possesses that important property of a metal, the capability of uniting *energetically* with chlorine" Is it to be understood from all this that a chlorine compound which is not produced by energetic union—say an endothermic compound like C_2Cl_4—is not a chloride?

These extracts may serve to show that the book requires to be carefully overhauled before it can be placed with confidence in the hands of a beginner

OUR BOOK SHELF

Vegetable Wasps and Plant Worms, a Popular History of Entomogenous Fungi, or Fungi parasitic upon Insects By M C Cooke, M A, LL D, A L S [364 pp 4 pl and figs in text] (London S P C K, 1892)

IT is somewhat surprising that a book on a subject of such importance alike to the entomologist and fungologist has not been forthcoming long ago It is true that a Memoir on the subject was undertaken thirty-five years ago by Mr G R Gray, but, being privately printed, was limited in circulation To this work Dr Cooke admits his indebtedness for a large amount of information bearing on the entomological aspect of the subject, and it is to be regretted that he was not aware of the existence of a much extended manuscript revision of the same work, at present in the Botanical Department, Natural History Museum

Dr Cooke's book is professedly a popular work on the subject, and consequently does not deal with the economic side, relating to such matters as the "muscardine" or silkworm disease, further than to indicate the nature and affinities of the fungus causing the disease

The fungi parasitic upon insects are arranged under four primary groups. the *Cordyceps* group, the *Laboulbeniaceæ*, the *Entomophthoræ*, and lastly a heterogeneous collection of moulds, which, with few exceptions, are not truly parasitic and destructive The structure and general characteristics of these groups, with glimpses of their life-history, are dealt with in an introductory chapter Entomologists, whose main interest will be to ascertain the name of any fungus parasitic on an insect, will find this a comparatively easy matter, as the general arrangement is an entomological one, commencing with the Hymenoptera, and under each is given an account of all the fungi that are known to be parasitic upon species included in the order Numerous woodcuts in the text and four plates assist very materially in the determination of species. From the mycological standpoint the arrangement indicated above is purely artificial, and introduced

for a purpose, while for the benefit of those who desire to know more of the inter-relationship of the fungi enumerated, a classified list is given of all the species, arranged under their respective families, including the distribution and name of the host

For the general reader, who is not specially interested in either insects or fungi, there is a considerable amount of interesting information bearing on such subjects as vegetable caterpillars, vegetable wasps, foul-brood of bees, &c, and the interest is not lessened by following the transition from the romantic and highly imaginative accounts given by early travellers of these productions, to the statements in accordance with modern knowledge There is a slip on p 35, *Cordyceps Sheeringii* should be *C Sherringii* The indices are very complete and the figures, excepting one on p 10, good

Notes on Qualitative Chemical Analysis By P Lakshmi Narasu Nayudu, B A (Madras K Murugesa Chetty, 1892)

IT is interesting to meet with books such as this, which serve to indicate how the study of chemistry is progressing in the colonies and dependencies of the empire

The author sets out with the endeavour to keep the *rationale* of the various processes of qualitative analysis well to the front, as in this way he considers the value of the study as a means of scientific training can alone be brought out Group-reagents and the reasons for their use are first discussed as a preliminary to a somewhat exhaustive study of the reactions of the different basic and acid radicles At the end of each group tables are given showing at a glance the behaviour of the radicles towards the various reagents

It is somewhat astonishing that after such a minute study of the reactions of all the more common radicles, the author should give no schemes for the separation of the constituents of the different group-precipitates In spite of the fact that under each radicle he gives as many, if not more, reactions than are given in the larger works on qualitative analysis, he contents himself with merely going through the examination of a simple salt The expenditure of but little space would remedy this omission, which limits the sphere of usefulness of the book. It is to be noted also that film-tests find no place in the system adopted

It may be said that the author adheres well to his purpose of showing why any particular operation is performed The book contains a large amount of useful information Occasionally, however, the mode in which it is stated is peculiar "In the cold" is an expression commonly used in speaking of a reaction The use of "in the heat," a term often employed by the author, is, on the other hand, uncommon To speak, too, of "neutral solutions of zinc salts containing strong acids" is confusing In some cases, as when using bodies like potassium metantimoniate or sodium hydrogen tartrate, it would be advisable to give the name as well as the formula. it isn't every student who is acquainted with such substances It is erroneous to say that fluorine does not combine with carbon even at a high temperature. According to Moissan, all the allotropes of carbon, except the diamond, unite with fluorine, indeed some of the forms are, in the cold, spontaneously inflammable in the gas

The following typographical errors are omitted in the list of errata. On p. 47 "meterially" should be "materially," "gSo_4," &c should be "$MgSo_4$," &c on p 58, and "Ba_2P_2O" is given for "$Ba_2P_2O_7$" on p 69

Science Instruments. Catalogue of Scientific Apparatus and Reagents manufactured and sold by Brady and Martin. (Newcastle-on-Tyne, 1892)

AT the present time, when almost all branches of experimental science are growing so rapidly, and new and improved pieces of apparatus are continually coming into existence, it is satisfactory to find that instrument makers are trying to keep pace with the times, and to afford purchasers the means of ascertaining with the minimum trouble what apparatus can be obtained to serve a particular end This catalogue is an instance that such is the case It is a well-bound book, profusely and clearly illustrated The different kinds of apparatus, useful both for teaching and for technical purposes, are well classified To prevent mistakes in ordering, each piece of apparatus is separately numbered, and where a new form is figured, a few lines are added explanatory of the principle involved

The instruments quoted belong to various branches of experimental science—chemistry, bacteriology, physics, mechanics, and meteorology A selection of instruments made by the Cambride company, and miscellaneous apparatus, diagrams, chemical reagents, &c, are also included

The sections on bacteriology and gas analysis are especially full, and indicate the interest at present taken in these departments

A table of contents and an index are supplied On p 145 "Irish" is misprinted for "Iris", and what is termed an "optical bank," on p 164, is usually called an "optical bench."

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Universities and Research.

AT the discussion in Edinburgh on the proposed National Laboratory, Lord Kelvin and Sir Geo Stokes took marked exception to my contention that the primary business of Universities was research, contending that it was teaching In a sense their contention is true, but not in contradistinction to my contention The distinction would hardly be worth fighting over were it not that they took up the further ground that only those researches should be engaged in in Universities which were likely to interest the students Of course the leaders of science can if they choose sell the great birthright of Universities for a mess of fees, but I hope they will not be permitted to do so without protest What view the democracy take of Universities is of the very last importance with our democratic institutions, and I trust all those who have the welfare of the nation at heart will protest against the Universities being turned into coach houses In this connection it is most important to bear in mind the distinction between the functions of Universities and those of schools and colleges The function of these latter is primarily to teach those who resort to them The function of the University is primarily to teach mankind In former days, when the means for distributing information were very imperfect, students used to flock from all sides to learn directly from a great mind Nowadays the great mind distributes his teaching broadcast In old days the only way to learn what was being done to advance knowledge was to go to the place where knowledge was being advanced Nowadays we read the Transactions of our learned societies at home. But at all times the greatest men have always held that their primary duty was the discovery of new knowledge, the creation of new ideas for all mankind, and not the instruction of the few who found it convenient to reside in their immediate neighbourhood Not that I desire to minimize the immense importance of personal influence, it is overwhelming; but it is a question quite beside the one at issue, which is whether the advance of knowledge by research and the teaching of the whole nation by the discoveries made is not rather the primary object of Universities than the instruction of the few students who gather in their halls: that is the real question at issue between Lord Kelvin, Sir Geo. Stokes, and myself. Are the Universities to devote the energies of the most advanced intellects of the age to the instruction of the whole nation, or to the instruction of the few

whose parents can afford them an, in some places fancy, education that can in the nature of things be only attainable by the rich?

In view of the discussion upon the proposed Teaching University for London it is to be hoped that these things will not be overlooked amid the local questions and rival institutions It is to be hoped on the one hand that those who will have the privilege of learning in the greatest city in the world will not be deprived of the personal influence of its greatest men by relegating these to some haven of laboratories where no bracing breath of students shall interfere with the inmates On the other hand it is to be hoped that London will so far honour itself as not to be content until it sees its University a centre of thought and investigation from which shall radiate new ideas and discoveries to enlighten and benefit the whole nation Before I close there is a matter of great importance to which I fear sufficient importance is not attached by those who are directing this matter and that is the great objections there are to mixing up Universities and Colleges with examining boards. We here in Trinity College, Dublin, suffer very much from the fact that a considerable number of our students never reside here, but only come over for periodical examinations We only suffer in one way, while if London adopted this abominable arrangement it would suffer in two ways We suffer because our degree is much less valued than it would be if all our students were compelled to reside All our students have not that education got by friction with their fellows and by contact with trained intellects which no examination can test, and which is such a valuable training, and in consequence our degrees are the less valuable London would suffer in this way, and it is a very serious way too In addition to this London would suffer from the inordinate importance that would be attached to extern examiners if the University examined London and extern students So far we have escaped this danger, but it is inevitable in London because the extern element there would be large, influential and organized, while with us it is of little strength The result would be to perpetuate and intensify that horrible teaching for examinations which is so necessary an evil in the case of the majority of students, but from which the leaders of thought should be exempt It matters not that the syllabus nor even that the very questions are approved by the professor, if the examination is conducted to any serious extent by an independent mind The student will seek a coach, who will probably teach him very well indeed, but whose whole view of learning will be of the passing-an examination type, and who will infect his pupil with this miserable disease Gradually the professor himself will be involved in the vortex, and the whole University will gradually look upon the passing of examinations as the end of life for students, and this is the acme of coaching and the bathos of education

GEO FRAS FITZGERALD

Trinity College, Dublin, November 25

The Stars and the Nile

AFTER reading Mr J Norman Lockyer's papers on the connection of the orientation of Egyptian temples with the heliacal rising of certain stars, I was interested to find that a custom still exists in the neighbourhood of the Second Cataract having a strong resemblance to the old Egyptian custom

The Nuba people of this part foretell the first rise of the Nile by the heliacal rising of the Pleiades, or as they call it, "Turáya." For Sirius they have no special name, calling it merely "the driver" or "follower" of the three stars (Orion).

It must be remembered that the first sign of the rise at Wady Halfa occurs at the beginning of June, reaching Assouan about a week later, but for some days the increase is very slow, and scarcely perceptible except in the readings of the Nile gauges.

These Nuba people still preserve in their language many ancient Egyptian words, and possibly we may have here a trace of the old custom, the Pleiades being taken instead of Sirius on account of the earlier date of the rise in the district of the Second Cataract than in Egypt itself.

H G LYONS, Capt. R E

Cairo, November 14.

A Palæozoic Ice-Age

THE account by Dr Wallace in NATURE (p 55) of glacial deposits recently discovered in Australia is a most important and welcome addition to our knowledge But to us the surprising circumstance is that Dr. Wallace appears quite unaware of the fact that this is only an addition to a great series of discoveries, by no means confined to Australia, affording evidence of a Palæozoic ice age That the deposits near Sandhurst are Palæozoic may, in the absence of any indication to the contrary, be assumed, since they are clearly similar in position and character to the well-known boulder beds of Bacchus Marsh, and these have been correlated with the strata containing ice borne fragments, amongst the marine beds west of Sydney and also at Wollongong to the southward, and in Queensland to the northward All these beds have been shown to be upper carboniferous A good account of the facts known up to 1886 may be found in Mr R D Oldham's paper on the Indian and Australian coal-bearing beds (Rec Geo Surv Ind xix p 39).

It is scarcely necessary to refer to the fact that extensive Palæozoic glacial deposits, of the same age as those of Australia, have been found in several parts of India, some as far within the tropic as lat 18° N, others in the Salt Range of the Punjab, that the famous Dwyka conglomerates of South Africa are similar and in all probability contemporaneous, and that boulder beds of very possibly the same geological date have been observed in Brazil We should not have mentioned these but for the fact that the idea of a Palæozoic ice age is apparently novel to Dr Wallace We do not think, however, that the reason why so well-informed a naturalist is unacquainted with geological data long known to many is any mystery. It has become an accepted article of faith amongst most European geologists (there are, of course, exceptions) that no ice age occurred before the last glacial epoch, just as it is part of the geological creed that the carboniferous flora was of world-wide extension, and as it has become the prevailing belief that the deep oceans have been the same since the consolidation of the earth's crust Now the discoverers of glacial evidence in the carboniferous beds of India and Australia also assert that the carboniferous flora of those countries differed *in toto* from that of Europe and resembled the jurassic flora of European regions, and some of them add that the great southern flora of South Africa, India, and Australia must have inhabited a vast continent, part of the area of which is now beneath the depths of the Indian Ocean Partly from Indian and Australian geologists being regarded as heretics geologically, partly from other causes, the evidence of ice action in India and Australia has been generally ignored No better proof could be afforded of the fact that European geologists in general have omitted to notice the series of discoveries in the southern hemisphere and in India than the publication of Dr Wallace's paper

The glacial evidence as it now stands is extremely interesting and perhaps transcends in importance that of the Pleistocene glacial epoch For as the effects of the carboniferous ice-age were felt within the present tropics, either the earth's axis of rotation must have shifted considerably, or else the refrigeration of the surface must have been due to a cause distinct from that supplied by the late Mr Croll's theory, even when supplemented by Sir R Ball's amendment

Our own interest in the whole subject is chiefly due to the circumstance that we happened in 1856 to be the first who met with the ancient boulder-bed in India, and suggested that it might be explained by the action of ice The discoveries in Australia and South Africa were of course quite independent of those in India, but were, we believe, slightly later in date.

HENRY F BLANFORD

Geology of Scotland.

MAY I supplement Prof. Green's history of geological mapping in Scotland (NATURE, vol xlvii. p. 49) by pointing out that Mr Cruchley published, on March 23, 1840, "A Geological Map of Scotland by Dr MacCulloch, F R.S, &c, published by order of the Lords of the Treasury by S. Arrowsmith, Hydrographer to the King." This fine map is on the scale of four miles to an inch. From the omission of "the late" before MacCulloch's name, it seems possible that the plates were in course of engraving before his death in 1835.

GRENVILLE A J. COLE

Royal College of Science for Ireland, Dublin

British Earthworms

I ENTIRELY concur with Dr. Hurst's view that the supposed new species, described by the Rev Hilderic Friend as *L rubescens* is in reality Savigny's *L festivus* I may add a further reason for discarding the term *L terrestris*, Lin , and substituting *L herculeus*, Sav , for our common large worm Savigny himself used "Enterion terrestre" to indicate a worm differing considerably from *L terrestris*, Lin , in the position and extent of the clitellum , moreover it belongs to the genus *Allolobophora* and not to *Lumbricus* at all

With regard to the second "new" species, *A cambrica*, recently described by Mr Friend, I believe that it is merely a variety of *A chlorotica*, Sav

According to the description it *appears* to differ from the latter species in three points —(1) colour , (2) extent of clitellum , (3) number of spermathecæ

(1) Now, amongst my collection of British worms I find one, of which a water colour sketch taken from the living specimen closely resembles Mr Friend's description of the colour of *A cambrica* My notes as to size, habits, &c , agree with his description I have carefully re examined my specimen, and find that it agrees perfectly with *A chlorotica* , or, in other words, I find that *A chlorotica* may vary—as Hoffmeister knew that it did vary—so much as to resemble *A mucosa*, and I may suggest that it is a mimetic resemblance

(2) Further, with regard to the clitellum of *A chlorotica* , in the table given by the Rev Hilderic Friend, it is stated to cover somites 29-36 As a matter of fact the next somite, 37, is nearly always included This brings *A cambrica*, Friend, into harmony with *A chlorotica*, Sav

(3) Thus the only differential character left is the number of spermathecæ, and I cannot agree to the validity of a new species on this single character, several specimens should be examined to settle the point, as variation in this feature is known to occur

I take a certain amount of credit to myself for the useful faunistic studies on the earthworms of Great Britain, now being pursued by the Rev Hilderic Friend, for, if I mistake not, I put him in the way of recognizing their specific characters, when, some years ago, I named for him, with remarks thereon, sundry consignments of some scores of worms which he sent to me for that purpose WM BLAXLAND BENHAM

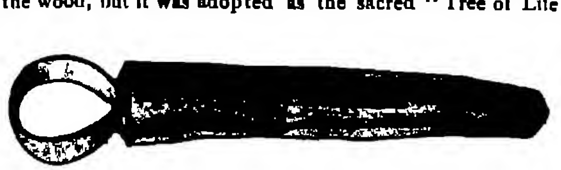
Egyptian Figs

THE accompanying sketch represents an instrument used in Egypt for removing the "eye" or top of the sycomore fig It is a piece of hoop iron, blunt on one edge and tolerably sharp on the other, and fixed into the end of a stick The fruit of *Ficus sycomorus*, or "Egyptian fig," seems to be invariably infested with the insect *Sycophaga crassipes*, Westw , which I am informed by Rev T. F Marshall, who has kindly given me the name, is the same insect supposed to effect caprification in Malta, judging from specimens which I sent him This fig never produces ripe seed in Egypt, though it has been introduced from the earliest times Not only are the ancient coffins made of the wood, but it was adopted as the sacred "Tree of Life



It probably came from Yemen, where Dr Schweinfurth saw many seedling trees growing spontaneously. The tree bears three crops per annum, in May, June, and August—September. Boys cut off the top of the figs of the first two crops only. Dr E. Sickenberger, one of the professors in the School of Medicine, Cairo, informs me that the figs have no pleasant flavour until the operation has been performed —"They then become very sweet, but remain smaller than when not cut open. The object is *to let the insects escape* Those that are left become watery and tasteless, and are full of *namoos* or sycophaga." In his first description Dr. Sickenberger described the instrument as "a kind of thimble made of iron plate ending in a spatula like a finger-nail. It is fixed on the thumb of the right hand. The operation is only made on fruits which shall be picked up the following day The day after the operation the fig is quite ripe The male flowers in those figs are all aborted, and the females have never perfect seeds The figs of the third generation are larger, of an agreeable taste, and sweet-scented , but they are not operated upon, only because in August and September, though the trees are much fuller of fruit than in May and June, the people have so much to do at that time They are seldom sold, and only eaten by the owners of the trees, or else they are abandoned to the field mice, birds, and dogs, which latter are very fond of them These *nilg* fruits are full of sycophaga '

It will be seen that the instrument he has sent me is of a different shape to the one he describes , and the chief interest lies in the fact that Pliny also describes the process as closely corresponding with this modern method He even uses a similar term "nail" (ὄνυχας) πέπτειν οὐ δύναται ἂν μὴ ἐπικνισθῇ ἀλλ' ἔχοντες ὄνυχας σιδηροῦς ἐπικνίζουσιν ἃ δ' ἂν ἐπικνισθῇ, τετάρταια πέπτεται (*Nat Hist* xiii 14) Further, the Prophet Amos describes himself as *bôlês siqmîm* , and the authors of the LXX, writing in Alexandria, appear to have understood the expression and translated these words by κνίζων συκάμινα This is the same verb as that which Pliny uses , so that it would seem to be pretty certain that Amos performed identically the same operation on the figs as is still done in Egypt at this day It will be noticed that the idea was to ripen the figs It does not really do this, because there are no seeds , but it does make the fig sweeter It also liberates the insects, and without doing this the figs would be uneatable Jerome is the only author, as far as I know, who alludes to "grubs" being inside the fig

GEORGE HENSLOW

Iridescent Colours

THE article "Iridescent Colours" on p 92 puts me in mind of a notice which I published thirty years ago, while I lived in the United States It was entitled "Harmonies of Form and Colour" (*Stettiner Entom Zeitung*, 1862, pp 412–414), and a portion of it refers to the subject of the above-mentioned article in NATURE, and may be of interest to its readers —

"A fundamental observation, which proves the influence of the intensity of light upon colour, may be made on some insects of metallic coloration, inhabiting a large area from north to south About six years ago, while in Southern Russia, I took a walk during sunset, and was struck by the brilliancy of some metallic red *Chrysomelæ*, abundant in that locality I found that it was the common *C. fastuosa*, which I did not recognize at once, because in the environs of St Petersburg, where I lived at that time, it occurs in its metallic-green variety, with an iridescent blue stripe on each of the elytra. Still farther north it assumes a more violet metallic colour. The same is the case with *Chrysomela cerealis* and *C graminis* The first of these species is represented in St Petersburgh in the blue variety (*C ornata*, Ahrens), while the typical variety, occurring farther south, has purplish-red metallic stripes. It is evident therefore that the metallic colouring of these wide-spread species is gradually intensified from north to south, in the order of the colours of the spectrum. We may imagine the area which these beetles occupy, like an immense rainbow, reflected from their backs, violet in the north, red in the south ; the violet perhaps connected in some way with the magnetic phenomena prevailing in the polar regions. The longicorn beetle (*Callidium violaceum*) undergoes the same variation : violet in the north, blue in central Europe." C R OSTEN SACKEN

Heidelberg, Germany, November 27

The Afterglow

THERE has been for three weeks past a very remarkable renewal of the afterglow There is a quite deep secondary red glow after the stars are fully out. I should say that no such afterglow has been seen since 1886, or three years after the Krakatão eruption. There is also a great extension of the white hazy atmospheric corona around the sun, very marked also around the moon. I am unable, however, to make out any of the pink colour on the outer edge of the haze, which was so char-

acteristic of "Bishop's Ring," and distinguishable at Honolulu for two years Apparently there has recently been a great re-inforcement added to the material in the upper atmosphere, which produces the afterglows

Is this owing to the August eruption in Alaska, which is said to have distributed ashes at a distance of 250 miles?

Prof C J Lyons, in charge of tidal observations in Honolulu, reports the period of highest mean tide to have extended itself this year into November, or fourteen months later than the last similar period The mean sea level is now over ten inches higher than it was last April It is also somewhat higher than has been shown by any previous tide registers in Honolulu Mr Lyons regards this as of special importance, taken in connection with the oscillation of the earth's axis, now established by the combined observations at Berlin and Honolulu

Honolulu, November 8 SERENO E BISHOP

OSMOTIC PRESSURE

OF the various properties which have found a common explanation in the new theory of solutions, there are none perhaps to which more interest attaches than to osmotic pressure, and although, on account of the experimental difficulties, the observations as yet accumulated on this subject are but scanty, they have so largely contributed to the novel ideas involved in the new theory, that they merit special attention

Since accounts of osmotic pressure are finding their way into few English text books, it may be worth while glancing at the main features which have led up to the present state of the question

It has long been known that if an aqueous solution—say, of sugar—be separated from pure water by a piece of animal membrane, that movements of the water and of the sugar take place through the membrane If the solution be contained in an open vessel, the base of which is composed of membrane, on partially immersing the vessel in water it is easy to see that more water enters the vessel than solution leaves it The level of liquid within rises above that without the vessel, different pressures being thus set up on opposite sides of the membrane

To this process wherein currents pass through a membranous septum, the terms "osmosis," "osmose," and "diosmose" have been applied The last of these is perhaps to be preferred, as it serves to indicate that two currents are involved in the phenomena Investigations carried out as indicated above were concerned with the measurement of what was termed the "endosmotic equivalent" That is the ratio of the amount of water passing *into* the solution to the amount of dissolved substance passing in the opposite direction Consistent measurements of this quantity could not be obtained, however, for it was found that the nature of the membrane exercised a marked influence upon its magnitude The kind of membrane employed, or, with the same membrane, its thickness or freshness, or even the direction in which water passed through it, was of importance Thus in illustration of the last point, water passes more readily outwards through eel's-skin, more readily inwards through frog's-skin

To obtain quantitative relations in this field it thus became essential to eliminate the influence of the membrane, and more recently this end seems to have been attained by the use of membranes artificially prepared

These artificial membranes differ from those of animal origin in the remarkable particular that although they allow water to pass through, they present a barrier to the passage of certain dissolved substances On this account they have been termed semi-permeable membranes, and by their use measurements of osmotic pressure have been made possible

To carry out such measurements the first point to be solved was to obtain a membrane of sufficient strength The substance which has been found to be most satisfactory as a membrane-former is copper ferrocyanide When aqueous solutions of potassium ferrocyanide and copper sulphate are carefully brought into contact a pellicle of copper ferrocyanide is formed where the two solutions meet In this condition the pellicle is much too fragile to sustain even slight differences of pressure, but by the following simple device, employed first of all by W Pfeffer, satisfactory results have been obtained.

If a cell similar to the ordinary porous pot of a voltaic battery be lowered into a solution of copper sulphate while at the same time a solution of potassium ferrocyanide be poured into its interior, the two solutions meet somewhere within the walls of the cell and deposit a film of copper ferrocyanide Little diaphragms of membrane are thus produced stretching across the pores of the cell-wall, which furnishes the necessary support, and by taking suitable precautions a membrane may thus be obtained capable of withstanding a pressure of several atmospheres

The behaviour of a solution when separated from pure solvent by such a semi-permeable membrane differs markedly from what takes place when an animal membrane is employed In the latter case, at the outset water adds itself to the solution, the level of liquid and the pressure on the solution-side of the membrane thus rise until a maximum pressure-head is attained, which, roughly speaking, is greater the stronger the solution used Seeing, however, that dissolved substance is continually escaping from the solution through the membrane, as soon as the maximum is reached the pressure-head begins to fall until eventually it vanishes, the levels of liquid on either side of the membrane being the same

If, on the other hand, a semi-permeable membrane be employed, as before, a maximum pressure is attained, but since dissolved substance cannot leave the solution, this maximum pressure as well as the concentration of the solution remain constant

When this constant state of things is established the excess of pressure on the solution-side of the membrane over that on the solvent-side, whatever it may mean, is termed the "osmotic pressure" of the solution It is therefore customary to reserve the term osmose to phenomena relating to semi-permeable membranes, diosmose being used in cases where, as with animal membranes, dissolved substance as well as solvent can traverse the membrane. It is obvious that when the pressure is established as indicated above, the original concentration of the solution has been altered by the entrance of solvent, and the observed osmotic pressure refers of course to the solution having the final concentration. If, however, we imagine the vessel containing the solution to be closed at the top, a quantity of air being imprisoned over the solution, pressure may be set up by compressing this air, only a small quantity of solvent being allowed to enter If, further, the air enclosure be tapped by a manometer, measurements of the pressure may be taken, and by making the air enclosure and the volume of the manometer small enough the quantity of solvent entering while pressure is being established may be neglected, the original concentration of the solution remaining practically unaltered This is the principle of the method employed in measuring osmotic pressure in absolute units.

The question now arises, "Are these measurements really independent of the nature of the membrane? Has the difficulty which beset the older experiments been overcome?" To this question an immediate answer is forthcoming, for, as pointed out by Prof Ostwald, it follows from theoretical considerations that if the membrane employed is really semi-permeable, the observed osmotic pressure of a given solution must be the same, no matter of what material the membrane is com-

posed For suppose we have a quantity of solution enclosed in a tube, one end of the tube being closed by a membrane A, the other by a membrane B, and suppose it possible that a pressure P can be developed on the membrane A when it separates the solution from pure water, which is higher than the pressure p similarly developed when B separates the solution from pure water On immersing the tube in water, the latter will begin to pass through both membranes into the solution When the pressure p is attained passage through B will stop, but that through A will continue, but as soon as the pressure on the solution rises above p, water will be forced out through B The pressure P will thus never be attained, water will continuously enter through A, and pass out at B We will thus have a machine capable of doing an infinite amount of work, which is impossible. Similar reasoning shows that p cannot be greater than P, it follows therefore that the pressure developed on each membrane is the same, that the osmotic pressure must be independent of the nature of a truly semi-permeable membrane

Actual observations are on record in which the osmotic pressure did appear to vary with the membrane employed A sugar solution, for example, exhibited a much lower osmotic pressure with a membrane of Prussian blue or calcium phosphate than with copper ferrocyanide From the preceding argument it is concluded, however, that these membranes giving the lower values were not quite firm or not quite impermeable to the dissolved substance; the highest value is thus taken as the measure of the osmotic pressure which is nearest the truth

On glancing at the results which have been obtained, the first point which strikes one is the extraordinary magnitude of the pressures thus set up In the case of a 1 per cent. aqueous solution of nitre the pressure attains the value of 2½ atmospheres This value increases with the strength of the solution till at 3 3 per cent it is no less than 6 atmospheres, this pressure being the highest which any membrane yet prepared has been able to withstand With substances like sugar, other things being the same, the pressure is not so great, but in all cases, in order to keep it within workable limits, the solutions employed have to be dilute

Striking as the results are themselves, their explanation is not less remarkable The original measurements of osmotic pressure were made with the purpose of elucidating the movement of liquids in plant cells, and naturally the substances examined were such as occur in the vegetable organism—aqueous solutions of sugar, gum, dextrin, and the nitrate, sulphate, and tartrate of potassium For some years after these observations were made, they lay comparatively unnoticed, until Prof van't Hoff, of Amsterdam, turned them to a use undreamt of by their discoverer From a study of the properties of dilute solutions van't Hoff came to the conclusion that the osmotic pressure was due to the bombardment of the molecules of the *dissolved substance* on the semi-permeable membrane. For when the osmotic pressure is established and equilibrium exists between solvent and solution, in the same time, equal amounts of solvent, must pass in either direction through the membrane and the impacts of the solvent molecules on the membrane will then be equal and opposed on either side, and therefore negligible On this reasoning the pressure recorded on the manometer is taken to be that exerted by the substance in solution

On examining the magnitude of the pressure thus attributed to the dissolved substance, in the case of a solution of sugar van't Hoff next showed that it bore the closest resemblance to the pressure of a gas Indeed, if we calculate the pressure of a gas which at the same temperature contains as many molecules per unit volume as there are molecules of sugar per unit volume of solution, then the pressure of the gas and the osmotic pressure are the same. Moreover, on thermodynamical grounds it was established that on the above hypothesis as to the nature of osmotic pressure its magnitude should be quantitatively connected with measurements of other physical properties of solutions, more especially those on the lowering of the vapour-pressure, and of the freezing point of a solvent produced by the presence of dissolved material In this way a mass of evidence was collected, a general survey of which led to the foundation of the new theory of solutions On this theory the dissolved substance, if the solution be dilute, is supposed to behave as if it were gaseous, the pressure it exerts—the osmotic pressure—being equal to the pressure which it would exert if it were gasified, and occupying, at the same temperature, a volume equal to the volume of the solution

Unfortunately measurements of osmotic pressure have only been made on few substances, and only for solutions in water, but on turning to all the available observations to see how they support this novel conclusion, the most superficial examination serves to show that an agreement does not exist Unless in the case of sugar, for no substance of known formula which has yet been investigated does the osmotic pressure agree with the corresponding gaseous pressure These substances consist of salt solutions, and they invariably give higher osmotic pressures than theory demands Similar disturbing influences have been observed when other physical properties of these solutions were measured, and to account for the facts an additional hypothesis has been put forward by Dr Svante Arrhenius

Salt solutions are electrolytes, they conduct the electric current, and undergo simultaneous chemical decomposition into their constituent ions Experiment shows that such electrolytic solutions give high osmotic pressures, more particles appear to bombard the semi-permeable membrane than if the dissolved substance behaved as a gas The new hypothesis states that this is really the case, the additional number of particles being produced from the breaking up of the dissolved substance It states that in a solution which can be electrolyzed a portion at least of the dissolved substance exists already decomposed or dissociated into its ions, and that although these ions cannot be separated by diffusion they are so far independent that each can exercise an effect on the semi-permeable membrane

The extent of this electrolytic dissociation is supposed to vary with the chemical nature of the dissolved substance, and to increase with the dilution In very dilute solutions it may be complete, the whole of the dissolved substance being supposed to exist in the state of ions

The second hypothesis gives, therefore, some explanation why the osmotic pressure of a salt solution is greater than that of a non-electrolytic solution of sugar, it further fixes the limits between which the osmotic pressure ought to vary in the case of an electrolyte, for the lower limit should be that of undissociated gas, the higher should be that of completely dissociated gas, each original molecule having decomposed into as many submolecules as there are ions in each molecule of salt

So far as these limiting conditions go, the facts support the hypothesis In all cases the observed osmotic pressure is either equal to one or other of the limits, or lies between them A closer scrutiny leads, nevertheless, to apparent discrepancy. It is evident that a measure of the amount of dissociation can be obtained from osmotic pressure observations. For if we divide the observed osmotic pressure by the corresponding pressure of undissociated gas we have obviously, if the preceding hypotheses are valid, the ratio of the actual number of bombarding molecules to the theoretical number had no dissociation occurred The ratio of these two numbers is denoted by the letter "i," a factor first used by van't Hoff. Now, on the new theory, the value of "i" can be

obtained by measurements of other properties of salt solutions, the electric conductivity, the depression of the freezing point, &c, and the theory is compared with practice by seeing if the values of "*i*," as determined, say, from freezing point observations, agree with those deduced from the osmotic pressure The comparison shows that in some cases, some half-a-dozen in all, the two sets of values correspond, in others, and in by far the majority, no such correspondences exist In these latter instances it is argued, and with a certain amount of experimental evidence, that the salts were not without action on the membrane employed, and that, therefore, diosmose really took place, the membrane was not truly semipermeable In this way the discordant observations have been put out of court.

It is thus apparent that the leading hypotheses of the new theory do not receive confirmation of the weightiest kind from observations on osmotic pressure. Indeed, were they supported by such measurements alone, they would hardly be entertained Their mainstay, however, lies in the mass of experimental work on many other properties—evidence which it is much easier to obtain than the difficult measurements on osmotic pressure—which has been correlated and explained by their use been put forward in favour of the gaseous analogy Several physicists, starting from entirely different points of view, have arrived at the result that in a dilute solution the dissolved substance should obey laws similar to those which hold for gases At present the attitude of the prominent upholders of the new theory is one of indifference as to the exact mechanism of osmotic pressure. The numerical agreement between the measurements on solutions and those on gases is regarded as ample justification for considering dissolved substances to be in a *pseudo*-gaseous condition

Whatever the ultimate explanation of the facts may be, there can be no doubt that the existing speculations on the nature of osmotic pressure and allied phenomena have infused new life into the study of solutions Indeed, as instigators to fresh inquiry these hypotheses must take rank as the most fruitful of recent times.

J. W RODGER

A SANITARIAN'S TRAVELS

MR ROBERT BOYLE has travelled round the world no fewer than four times for the purpose of studying sanitary science and preparing the way for the intro-

GREAT RECUMBENT FIGURE OF BUDDHA, PEGU, BURMAH

It is only fair to add that both hypotheses, from physical as well as chemical standpoints, have met with a measure of adverse criticism The *rôle* played by the membrane has also been questioned It has been suggested that it is not really semi-permeable, allowing solvent only to pass, but just as a porous plug behaves towards a mixture of gases, it allows molecules with different momenta to traverse it at different rates Or, again, its action has been likened to that of a palladium film towards hydrogen, compounds being formed with the membrane substance on one side, these becoming diffused and dissociated on the other If either of these views be correct the pressures exerted by dissolved substances have probably never been measured

On the other hand, important theoretical support has duction of the ventilating and sanitary appliances he has invented. An interesting account of his fourth journey is given in a little book entitled "A Sanitary Crusade through the East and Australasia," consisting of a series of papers reprinted from the *Building News* In the course of this "crusade" Mr Boyle visited Burmah, the Malay native states, Sumatra, Siam, Borneo, Java, Australia, New Zealand, Samoa, the Sandwich Islands, and America. Of all the facts noted by him as a sanitarian the most remarkable are those relating to leprosy, a disease which he believes to be spreading to an alarming extent all over the world. He was particularly struck by the gigantic proportions the evil has assumed in Burmah The steps of the great Shwedagon pagoda at Rangoon, the Mecca of the Indo-Chinese Buddhists, he found to be

"closely lined from top to bottom with lepers, suffering from that loathsome disease in its worst forms and most advanced stages" A number of the victims examined by Mr Boyle "presented a most sickening and awful spectacle" Yet no provision worthy of the name appears to be made for the maintenance or treatment of these poor lepers, who are thus compelled to resort to begging to keep themselves in existence At Mandalay Mr Boyle came in contact with horrors of a similar nature During times of high festival the entrances of the great Arakan pagoda in that city are crowded by hundreds of lepers, so that the visitor has to pick his way carefully among them. In the Sandwich Islands also Mr Boyle was strongly impressed by the terrible effects of the curse of leprosy, which, he says, has nearly decimated the native population

He has a curious theory to the effect that the propagation of leprosy has been to a large extent connected with cannibalism, the disease "being spread wholesale through the eating of infected bodies" He has frequently seen in New Caledonia and the South Sea Islands human bodies "hanging up in the natives' huts, intended for future repasts, though then in an advanced stage of decomposition and exhaling a sickening odour"

The little book is by no means occupied only with these terrible subjects Reference is made to many interesting things which came under Mr Boyle's observation in the course of his journey We may especially note the impression produced upon him by Buddhist temples and various classes of objects associated with Buddhism in Burmah Pagan, an ancient capital of Burmah, situated on the Irrawaddy between Mandalay and Rangoon, contains an enormous number of Buddhist temples of various sizes and styles of architecture, and the city, as seen from the river, is described by Mr Boyle as "one of the grandest and most impressive sights he has ever seen." Lower down the Irrawaddy below Prome there is a cliff about two miles long and 300 feet high, on the face of which are carved innumerable figures of Buddha ranged in tiers from the bottom to the top He thinks that some of these figures cannot be less than twenty feet high Many of them are richly gilded, and the whole forms "a very brilliant and curious sight" We reproduce an illustration showing the great recumbent figure of Buddha, in the province of Pegu, of which Mr Boyle reports that "it is said to measure about 270 feet in length by 70 feet at the shoulder" In a paper read lately before the Anthropological Institute (see NATURE, November 10, p 46) Major R C Temple gives the length as 181 feet and the height at the shoulder as 46 feet This remarkable monument is built of brick, and Major Temple speaks of it as "well proportioned throughout." It is supposed to have been produced in the fifteenth century It was hidden from view by jungle until 1881, when it was accidentally discovered by a railway contractor

GAUSS AND WEBER

IN bringing before our readers the contents of a circular we have received with respect to the erection of a monument, in Gottingen, to the two world-renowned scientific workers and friends, Charles Frederick Gauss and William Weber, we do so, knowing that every scientific man, whether he be astronomer, mathematician, or physicist, will be only too glad to have a chance of paying some tribute, however slight, to their memory

Only about a year has gone by since the younger of the two, William Weber, passed away, having brought glory to the University of Göttingen, which was radiated throughout the whole scientific world. The work which both have done in the service of science cannot be said to be the property of their followers alone, but is a precious heirloom of mankind, which has proved, and will continue to prove in the future, valuable in many ways in the service of Technics, in methods of communication, and in civilization generally

Gauss, who is almost unequalled among the scholars of the century, has not only left imposing landmarks of his great mind in all domains of pure mathematics, but he has also by his work furthered all departments of its applications in astronomy and physics, while his investigations have become standard for the theoretical as well as for the observational side

What Gauss did for magnetism, Weber, whom Gauss had chosen for his fellow worker, attracted by his useful work on acoustics, did for the strength of galvanic currents, for their impelling electromotive forces, and for their resistances

Further, in teaching how to measure these quantities in absolute units, he has furnished extremely important methods for their investigation In this way not only has the science itself been furthered, but a firm basis for the development of electro-technics has been formed, the soundness of which is proved by its general adoption and which has contributed greatly to the tremendous advance witnessed during the last ten years The pamphlet then goes on to say "It is not the purpose of these lines to enlarge on the eminent works which we owe to the co-operation of these great investigators, we can only call to mind the fertile researches on the laws of the earth's magnetism, from which as it were a new branch of physics has developed; further, the attempts to encompass the phenomena of electrostatics, electrodynamics, and induction by one single law, attempts which, however a future generation may judge of them, will mark an important epoch in scientific development, and further, we may recall the most popular result of their co-operation, viz the erection of the first telegraph practically adopted for communication at a distance"

Since the year 1877 the birthplace of Gauss has possessed a memorial of him, but Göttingen, the place where he and Weber worked, and where the former died, and which consequently became celebrated, possesses no such memorial That this should be remedied is the object of this circular, and one has only to glance down the list of names attached to it—about 275 altogether—to see that it includes most of the learned men in Germany, and those of many distinguished foreigners Among these we are glad to see the name of Lord Kelvin, President of the Royal Society

The acting committee is composed of Prof Klein, E v Meier (Curator of the University), F Merkel (Prorector of the University), G Merkel (Over-burgomaster), Profs E Riecke, E. Schering, W Schur, W Voigt, H Weber, and S Benfey (banker), and it is to the last mentioned that subscriptions should be addressed (S Benfey, Bankgeschäft, Göttingen) The list will remain open until April 1, 1893

THE ANNIVERSARY OF THE ROYAL SOCIETY

YESTERDAY being St. Andrew's Day the anniversary meeting of the Royal Society was held in their apartments at Burlington House. The auditors of the Treasurer's accounts having read their report, and the Secretary having read the list of Fellows elected and deceased since the last anniversary, the President (Lord Kelvin) proceeded to deliver the anniversary address. The medals were then presented as follows —The Copley Medal to Prof Rudolf Virchow, For.Mem.R.S (received by the Foreign Secretary), for his investigations in Pathology, Pathological Anatomy, and Prehis-

toric Archæology; the Rumford Medal to Mr Nils C Dunér (received by the Swedish Minister), for his Spectroscopic Researches on Stars; a Royal Medal to Mr J N Langley, F R.S, for his work on Secreting Glands, and on the Nervous System, a Royal Medal to the Reverend Prof Pritchard, F R.S, for his work on Photometry and Stellar Parallax, the Davy Medal to Prof François Marie Raoult, of Grenoble, for his researches on the Freezing Points of Solutions, and on the Vapour Pressures of Solutions; and the Darwin Medal to Sir J D Hooker, F R S, on account of his important contributions to the progress of Systematic Botany, as evidenced by the "Genera Plantarum" and the "Flora Indica," but more especially on account of his intimate association with Mr Darwin in the studies preliminary to the "Origin of Species"

The Society next proceeded to elect the Officers and Council for the ensuing year The following is a list of those elected —President · The Lord Kelvin Treasurer Sir John Evans Secretaries Prof Michael Foster, The Lord Rayleigh Foreign Secretary Sir Archibald Geikie Other Members of the Council Capt William de Wiveleslie Abney, Sir Benjamin Baker, Prof Isaac Bayley Balfour, William Thomas Blanford, Prof George Carey Foster, Richard Tetley Glazebrook, Frederick Ducane Godman, John Hopkinson, Prof Joseph Norman Lockyer, Prof John Gray McKendrick, William Davidson Niven, William Henry Perkin, Rev Prof B Price, The Marquis of Salisbury, Adam Sedgwick, Prof William Augustus Tilden

In the evening the Fellows and their friends dined together at the Whitehall Rooms, Hôtel Métropole

The following is the address delivered at the anniversary meeting by Lord Kelvin —

Since our last Anniversary Meeting, the Royal Society has lost 27 Fellows on the Home list, and 5 Foreign Members, a sadly great number

Pedro (Dom) II. (d'Alcantara), Emperor of Brazil, December 5, 1891
Ramsay, Sir Andrew Crombie, December 9, 1891, aged 77
Stas, Jean Servais, December 13, 1891, aged 78
Bennett, Sir James Risdon, December 14, 1891, aged 82
Devonshire, William Cavendish, 7th Duke of, December 21, 1891, aged 83
Russell, William Henry Leighton, December 28, 1891, aged 68
Kronecker, Leopold, December 29, 1891
Wood, John, December 29, 1891, aged 66.
Airy, Sir George Biddell, January 2, 1892, aged 90
Henry, William Charles, January 7, 1892, aged 88.
Quatrefages de Bréau, Jean Louis Armand de, January 12, 1892, aged 81.
Adams, John Couch, January 21, 1892, aged 72
Paget, Sir George Edward, January 29, 1892, aged 83
Caird, Right Hon. Sir James, February 9, 1892, aged 76
Dittmar, William, February 9, 1892, aged 59.
Grant (Lieut -Col), James Augustus, February 11, 1892, aged 65
Hunt, Thomas Sterry, February 12, 1892, aged 66
Bates, Henry Walter, February 16, 1892, aged 67.
Hirst, Thomas Archer, February 16, 1892, aged 61
Kopp, Hermann Franz Moritz, February 20, 1892, aged 75
Gregory, Right Hon Sir William Henry, March 6, 1892, aged 75.
Knowles, Sir Francis Charles, March 19, 1892, aged 90
Bowman, Sir William, Bart., March 29, 1892, aged 76
Hofmann, August Wilhelm von, May 5, 1892, aged 74
Thomson, James, May 8, 1892, aged 71
Bramwell, George William Wilsher, Lord, May 9, 1892, aged 84.
Aitken, Sir William, June 25, 1892, aged 67
Schorlemmer, Carl, June 27, 1892, aged 58
Clark, Frederick Le Gros, July 19, 1892, aged 82
Sherbrooke, Robert Lowe, Viscount, July 27, 1892, aged 81
Sutherland, George Granville William Sutherland-Leveson Gower, Duke of, September 22, 1892, aged 64.
Tennyson, Alfred, Lord (Poet Laureate), October 6, 1892, aged 83
Calver (Captain), Edward Killick, October 28, 1892.
Biographical notices will appear in the Proceedings

During the past year, in the mathematical and physical section of the "Philosophical Transactions," eighteen papers have been published, and in the biological section, eleven, the two sections together containing a total of 1235 pages of letterpress and 50 plates Of the "Proceedings," fourteen numbers have been issued, containing 1223 pages and 20 plates This unusually large bulk is partly accounted for by the publication in the "Proceedings" of certain extra matters which the Council deemed likely to interest the Fellows One part (No 307), which forms an appendix to volume l, contains results of the Revision of the Statutes, to which I alluded in my Anniversary Address last year It consists of a summary of the second and third chapters, and a copy of the Statutes as now revised, followed by an interesting note on the history of the Statutes, which has been drawn up by our senior secretary, Prof Michael Foster In addition to these matters, the same number contains a complete list of the portraits and busts at present in the apartments of the Society, compiled by order of the Library Committee, a work which was much needed, as no such list had been made since Weld's Catalogue, printed thirty two years ago The new "list" is not a descriptive catalogue, but the names of the painters and donors, and the dates of the gifts, so far as a thorough and somewhat laborious examination of the Council minutes and Journal books has revealed them, are furnished The list of portraits is followed by a full descriptive catalogue of the medals at present in the possession of the Society, which has been carefully made by our clerk, Mr James, under the supervision of the treasurer.

Another extra number of the "Proceedings" (No. 310) is devoted to a First Report of the Water Research Committee on the Present State of our Knowledge concerning the Bacteriology of Water, by Profs Percy Frankland and Marshall Ward It contains 96 pages, full of most valuable information regarding the vitality of micro-organisms in drinking water, to which in a large measure the spread of Asiatic cholera, typhoid fever, and other zymotic diseases is now known to be due

In my Presidential Address of last year, I referred to this Water Committee as having been appointed by the Royal Society, in alliance with the London County Council, and this first instalment of its work seems amply to justify its originators in their expectations of results, most valuable for the public health, from the investigation which has been commenced.

A third extra number (No 311) contains the report of the Committee on Colour Vision. This Committee, from the time of its appointment in March, 1890, held over thirty meetings, in course of which it examined more than 500 persons as to their colour vision, and tried various methods and many kinds of apparatus for colour testing The report of the results of the whole inquiry contains a large mass of most interesting matter, and the Committee's work ends in a set of practical recommendations, from which we may hope that much benefit will come, in the prevention of inconvenience and disaster liable to be produced by mistake of colour signals, both at sea and on railways

Mr Ellis's communication (Roy Soc. Proc, November, 1892, vol lii, p. 191) to the Royal Society of last May, and Prof. Grylls Adams' communication (Phil Trans, vol. clxxxiii. 1891–92, p 131) of June, 1891, both on the subject of simultaneous magnetic disturbances found by observations at magnetic observatories in different parts of the world; the award of a Royal medal two years ago to Hertz, for his splendid experimental work on electro-magnetic waves and vibrations, and Prof. Schuster's communication (Phil Trans vol. clxxx. 1889, p 467) to the Royal Society, of June, 1889, on the "Diurnal Variations of Terrestrial Magnetism," justify me in saying a few words on the present occasion regarding terrestrial magnetic storms, and the hypothesis that they are due to magnetic waves emanating from the sun.

Guided by Maxwell's "electro-magnetic theory of light," and the undulatory theory of propagation of magnetic force which it includes, we might hope to perfectly overcome a fifty years' out-

standing difficulty in the way of believing the sun to be the direct cause of magnetic storms in the earth, though hitherto every effort in this direction has been disappointing. This difficulty is clearly stated by Prof W. G. Adams, in the following sentences, which I quote from his Report to the British Association of 1881 (p. 469) "On Magnetic Disturbances and Earth Currents" — "Thus we see that the magnetic changes which take place at various points of the earth's surface at the same instant are so large as to be quite comparable with the earth's total magnetic force; and in order that any cause may be a true and sufficient one, it must be capable of producing these changes rapidly."

The primary difficulty, in fact, is to imagine the sun a variable magnet or electro-magnet, powerful enough to produce at the earth's distance changes of magnetic force amounting, in extreme cases, to as much as 1/20, or 1/30, and frequently, in ordinary magnetic storms, to as much as 1/400 of the undisturbed terrestrial magnetic force

The earth's distance from the sun is 228 times the sun's radius, and the cube of this number is about 12,000,000. Hence, if the sun were, as Gilbert found the earth to be, a globular magnet, and if it were of the same average intensity of magnetisation as the earth, we see, according to the known law of magnetic force at a distance, that the magnetic force due to the sun at the earth's distance from it, in any direction, would be only a twelve-millionth of the actual force of terrestrial magnetisation at any point of the earth's surface in a corresponding position relatively to the magnetic axis Hence the sun must be a magnet[1] of not much short of 12,000 times the average intensity of the terrestrial magnet (a not absolutely inconceivable supposition, as we shall presently see) to produce, by direct action simply as a magnet, any disturbance of terrestrial magnetic force sensible to the instruments of our magnetic observatories.

Considering probabilities and possibilities as to the history of the earth from its beginning to the present time, I find it unimaginable but that terrestrial magnetism is due to the greatness and the rotation of the earth. If it is true that terrestrial magnetism is a necessary consequence of the magnitude and the rotation of the earth, other bodies comparable in these qualities with the earth, and comparable also with the earth in respect to material and temperature, such as Venus and Mars, must be magnets comparable in strength with the terrestrial magnet, and they must have poles similar to the earth's north and south poles on the north and south sides of their equators, because their directions of rotation, as seen from the north side of the ecliptic, are the same as that of the earth It seems probable, also, that the sun, because of its great mass and its rotation in the same direction as the earth's rotation, is a magnet with polarities on the north and south sides of its equator, similar to the terrestrial northern and southern magnetic polarities. As the sun's equatorial surface-velocity is nearly four and a half times the earth's, it seems probable that the average solar magnetic moment exceeds the terrestrial considerably more than according to the proportion of bulk Absolutely ignorant as we are regarding the effect of cold solid rotating bodies such as the earth, or Mars, or Venus, or of hot fluid rotating bodies such as the sun, in straining the circumambient ether, we cannot say that the sun might not be 1000, or 10,000, or 100,000 times as intense a magnet as the earth It is, therefore, a perfectly proper object for investigation to find whether there is, or is not, any disturbance of terrestrial magnetism, such as might be produced by a constant magnet in the sun's place with its magnetic axis coincident with the sun's axis of rotation Neglecting for the present the seven degrees of obliquity of the sun's equator, and supposing the axis to be exactly perpendicular to the ecliptic, we have an exceedingly simple case of magnetic action to be considered: a magnetic force perpendicular to the ecliptic at every part of the earth's orbit and varying inversely as the cube of the earth's distance from the sun The components of this force parallel and perpendicular to the earth's axis are, respectively, 0.92 and 0.4 of the whole, of which the former could only be perceived in virtue of the varying distance of the earth from the sun in the course of a year; while the latter would give rise to a daily variation, the same as would be observed if the red ends of terrestrial magnetic needles were attracted towards an ideal star of declination 0° and right ascension 270°. Hence, to discover the disturbances of terrestrial magnetism, if any there are, which are due to direct action of the sun as a magnet, the photographic curves of the three magnetic elements given by each observatory should be analysed for the simple harmonic constituent of annual period and the simple harmonic constituent of period equal to the sidereal day. We thus have two very simple problems, each of which may be treated with great ease separately by a much simplified application of the principles on which Schuster has treated his much more complex subject, according to Gauss' theory as to the external or internal origin of the disturbance, and Prof. Horace Lamb's investigation of electric currents induced in the interior of a globe by a varying external magnet. The sidereal diurnal constituent which forms the subject of the second of these simplified problems is smaller, but not much smaller, than the solar diurnal term which, with the solar semi-diurnal, the solar ter-diurnal, the solar quarter-diurnal constituents form the subjects of Schuster's paper. The conclusion at which he has arrived, that the source of the disturbance is external, is surely an ample reward for the great labour he has bestowed on the investigation hitherto, and I hope he may be induced to undertake the comparatively slight extension of his work which will be required for the separate treatment of the two problems of the sidereal diurnal and the solar annual constituents, and to answer for each the question:—Is the source external or internal?

But even though external be the answer found in each case, we must not from this alone assume that the cause is direct action of the sun as a magnet The largeness of the solar semi-diurnal, ter diurnal, and quarter-diurnal constituents found by the harmonic analysis, none of which could be explained by the direct action of the sun as a magnet, demonstrate relatively large action of some other external influence, possibly the electric currents in our atmosphere, which Schuster suggested as a probable cause. The cause, whatever it may be, for the semi-diurnal and higher constituents would also probably have a variation in the solar diurnal period on account of the difference of temperature of night and day, and a sidereal and annual period on account of the difference of temperature between winter and summer.

Even if, what does not seem very probable, we are to be led by the analysis to believe that magnetic force of the sun is directly perceptible here on the earth, we are quite certain that this steady force is vastly less in amount than the abruptly varying force which, from the time of my ancestor in the Presidential Chair, Sir Edward Sabine's discovery,[1] forty years ago, of an apparent connection between sunspots and terrestrial magnetic storms, we have been almost compelled to attribute to disturbing action of some kind at the sun's surface.

As one of the first evidences of this belief, I may quote the following remarkable sentences from Lord Armstrong's Presidential Address to the British Association at Newcastle, in 1863:—

"The sympathy also which appears to exist between forces operating in the sun and magnetic forces belonging to the earth merits a continuance of that close attention which it has already received from the British Association, and of labours such as General Sabine has, with so much ability and effect, devoted to the elucidation of the subject I may here notice that most remarkable phenomenon which was seen by independent observers at two different places, on September 1, 1859. A sudden outburst of light, far exceeding the brightness of the sun's surface, was seen to take place, and sweep like a drifting cloud over a portion of the solar face This was attended with magnetic disturbances of unusual intensity, and with exhibitions of aurora of extraordinary brilliancy. The identical instant at which the effusion of light was observed was recorded by an abrupt and strongly-marked deflection in the self-registering instruments at Kew. The phenomenon as seen was probably only part of what actually took place, for the magnetic storm in the midst of which it occurred commenced before, and continued after the event If conjecture be allowable in such a case, we may suppose that this remarkable event had some connection with the means by

[1] The moon's apparent diameter being always nearly the same as the sun's, the statements of the last four sentences are applicable to the moon as well as to the sun, and are important in connection with speculation as to the cause of the lunar disturbance of terrestrial magnetism, discovered nearly fifty years ago by Kreil and Sabine.

[1] Communication to the Royal Society, March 18, 1852 (*Phil. Trans.*, vol. cxlii. p. 143).

which the sun's heat is renovated. It is a reasonable supposition that the sun was at that time in the act of receiving a more than usual accession of new energy; and the theory which assigns the maintenance of its power to cosmical matter, plunging into it with that prodigious velocity which gravitation would impress upon it as it approached to actual contact with the solar orb, would afford an explanation of this sudden exhibition of intensified light, in harmony with the knowledge we have now attained, that arrested motion is represented by equivalent heat."

It has certainly been a very tempting hypothesis, that quantities of meteoric matter suddenly falling into the sun is the cause, or one of the causes, of those disturbances to which magnetic storms on the earth are due. We may, indeed, knowing that meteorites do fall into the earth, assume without doubt that much more of them fall, in the same time, into the sun. Astronomical reasons, however, led me, long ago to conclude that their quantity annually, or per century, or per thousand years, is much too small to supply the energy given out by the sun in heat and light radiated through space, and led me to adopt unqualifiedly Helmholtz's theory, that work done by gravitation on the shrinking mass is the true source of the sun's heat, as given out at present, and has been so for several hundred thousand years, or several million years. It is just possible, however, that the outburst of brightness described by Lord Armstrong may have been due to an extraordinarily great and sudden falling in of meteoric matter, whether direct from extraplanetary space, or from orbital circulation round the sun. But it seems to me much more probable that it was due to a refreshed brightness produced over a larger area of the surface than usual by brilliantly incandescent fluid rushing up from below, to take the place of matter falling down from the surface, in consequence of being cooled in the regular *régime* of solar radiation. It seems, indeed, very improbable that meteors fall in at any time to the sun in sufficient quantity to produce dynamical disturbances at his surface at all comparable with the gigantic storms actually produced by hot fluid rushing up from below, and spreading out over the sun's surface.

But now let us consider for a moment the work which must be done at the sun to produce a terrestrial magnetic storm. Take, for example, the magnetic storm of June 25, 1885, of which Adams gives particulars in his paper of June, 1891 (Phil. Trans., p. 139 and Pl. 9). We find at eleven places, St. Petersburg, Stonyhurst, Wilhelmshaven, Utrecht, Kew, Vienna, Lisbon, San Fernando, Colaba, Batavia, and Melbourne, the horizontal force increased largely from 2 to 2.10 p.m., and fell at all the places from 2.10 to 3 p.m., with some rough ups and downs in the interval. The storm lasted altogether from about noon to 8 p.m. At St. Petersburg, Stonyhurst, and Wilhelmshaven, the horizontal force was above par by 0.00075, 0.00088, and 0.00090 (C.G.S. in each case) at 2.10 p.m., and below par by 0.0007, 0.00066, 0.00075 at 3 o'clock. The mean value for all the eleven places was nearly 0.0005 above par at 2h. 10m., and 0.0005 below par at 3h. The photographic curves show changes of somewhat similar amounts following one another very irregularly, but with perfectly simultaneous correspondence at the eleven different stations, through the whole eight hours of the storm. To produce such changes as these by any possible dynamical action within the sun, or in his atmosphere, the agent must have worked at something like 160 million million million million horse-power[1] (12×10^{35} ergs per sec.), which is about 364 times the total horse-power (3.3×10^{33} ergs per sec.) of the solar radiation. Thus, in this eight hours of a not very severe magnetic storm, as much work must have been done by the sun in sending magnetic waves out in all directions through space as he actually does in four months of his regular heat and light. This result, it seems to me, is absolutely conclusive against the supposition that terrestrial magnetic storms are due to magnetic action of the sun; or to any kind of dynamical action taking place within the sun, or in connection with hurricanes in his atmosphere, or anywhere near the sun outside.

It seems as if we may also be forced to conclude that the supposed connection between magnetic storms and sun-spots is unreal, and that the seeming agreement between the periods has been a mere coincidence.

We are certainly far from having any reasonable explanation of any of the magnetic phenomena of the earth; whether the fact that the earth is a magnet; that its magnetism changes vastly, as it does from century to century; that it has somewhat regular and periodic annual, solar diurnal, lunar diurnal, and sidereal diurnal variations; and (as marvellous as the secular variation) that it is subject to magnetic storms. The more marvellous, and, for the present inexplicable, all these subjects are, the more exciting becomes the pursuit of investigations which must, sooner or later, reward those who persevere in the work. We have at present two good and sure connections between magnetic storms and other phenomena: the aurora above, and the earth currents below, are certainly in full working sympathy with magnetic storms. In this respect the latter part of Mr. Ellis's paper is of special interest, and it is to be hoped that the Greenwich observations of earth currents will be brought thoroughly into relation with the theory of Schuster and Lamb, extended, as indeed Professor Schuster promised to extend it, to include not merely the periodic diurnal variations, but the irregular sudden changes of magnetic force taking place within any short time of a magnetic storm.

[1] 1 horse power = 7.46×10^{9} ergs per second.

In my Presidential address of last year I referred to the action of the International Geodetic Union, on the motion of Prof. Foerster, of Berlin, to send an astronomical expedition to Honolulu for the purpose of making a twelve months' series of observations, on latitude, corresponding to twelve months' simultaneous observations to be made in European observatories, and I was enabled, through the kindness of Prof. Foerster, to announce as a preliminary result, derived from the first three months of the observations, that the latitude had increased during that time by ½ sec. at Berlin, and had decreased at Honolulu by almost exactly the same amount. The proposed year's observations, begun in Honolulu on June 1, 1891, were completed by Dr. Marcuse, and an elaborate reduction of them by the permanent Committee of the International Geodetic Union was published a month ago at Berlin. The results are in splendid agreement with those of the European observatories Berlin, Prag, and Strasbourg. They prove beyond all question that between May 1891 and June 1892 the latitude of each of the three European observatories was a maximum, and of Honolulu a minimum, in the beginning of October, 1891; that the latitude of the European observatories was a minimum, and of Honolulu a maximum, near the beginning of May, 1892; and that the variations during the year followed somewhat approximately, simple harmonic law as if for a period of 385 days, with range of about ½ sec. above and below the mean latitude in each case. This is just what would result from motion of the north and south polar ends of the earth's instantaneous axis of rotation, in circles on the earth's surface of 7.5 metres radius, at the rate of once round in 385 days.

Sometime previously it had been found by Mr. S. C. Chandler that the irregular variations of latitude which had been discovered in different observatories during the last fifteen years seemed to follow a period of about 427 days, instead of the 306 days given by Peters' and Maxwell's dynamical theory, on the supposition of the earth being wholly a rigid body. And now, the German observations, although not giving so long a period as Chandler's, quite confirm the result that, whatever approximation to following a period there is, in the variations of latitude, it is a period largely exceeding the old estimate of 306 days.

Newcomb, in a letter which I received from him last December, gave, what seems to me to be, undoubtedly, the true explanation of this apparent discrepance from dynamical theory, attributing it to elastic yielding of the earth as a whole. He added a suggestion, specially interesting to myself, that investigation of periodic variations of latitude may prove to be the best means of determining approximately the rigidity of the earth. As it is, we have now, for the first time, what seems to be a quite decisive demonstration of elastic yielding in the earth as a whole, under the influence of a deforming force, whether of centrifugal force round a varying axis, as in the present case, or of tide-generating influences of the sun and moon, with reference to which I first raised the question of elastic yielding of the earth's material many years ago.

The present year's great advance in geological dynamics forms the subject of a contribution by Newcomb to the Monthly Notices of the Royal Astronomical Society of last March. In a later paper, published in the *Astronomische Nachrichten*, he examines records of many observatories, both of Europe and America, from 1865 to the present time, and finds decisive evidence that from 1865 to 1890 the variations of latitude were much less than they have been during the past year, and, seeming to show that an augmentation took place, somewhat suddenly, about the year 1890.

When we consider how much water falls on Europe and Asia

how a careful observer in the British Islands may form a good judgment of the coming weather. The lecturer showed, with the aid of diagrams, the tracks followed by storm centres, with reference to the conditions of areas of low and high pressure The reason why storms usually proceed in a north-easterly direction across or skirting these islands was explained as owing to the high barometer generally to be found in the Atlantic in the vicinity of the Azores, while in the neighbourhood of Iceland there is a region where the barometer is generally lower than in the space surrounding it The storms generally advance so as to leave the low pressure on their left, and the high pressure on their right—moving round the south and east sides of the prevailing low pressure Considerable stress was laid upon the importance of observing the cirrus clouds, the different motions of which, in conjunction with the indications of the barometer, are useful guides both as to the approach of a storm and the track along which the centre is moving. Several illustrations of these facts were given by the lecturer, who also gave many valuable hints as to what may be learnt from the published daily weather charts

THE Leeds Naturalists' Club seems to be in no hurry about the publication of its Transactions, those for the year 1890 having only just been issued The volume, however, has been prepared with great care, and shows that much good work is being done by the Club. Among the contents is a most interesting abstract of a lecture by the Rev Edward Jones on relics found in Yorkshire caves Reference was made to the cave at Kirkdale, near York, and the Victoria Cave of Settle, both of which have been well worked and have given valuable results, but attention was directed mainly to the cave found at Elbolton or Thorp, which is situated ten miles north of Skipton and two miles from Grassington Through the energy of the president and members of the Skipton Natural History Society, this cave, which has been handed over to them, has been worked with great earnestness, and many bones have been turned up Human remains, representing some thirteen bodies, have been found in an excellent state of preservation These human beings must have been buried there, as they were all found in a sitting position, with the knees brought under the chin The cave, however, was not used only as a burial-place, for the remains of charcoal fires, burnt bones, and pieces of pottery have been found At the time when the lecture was delivered, the excavations had not revealed anything older than the Neolithic period Among the finds are several specimens of bones of bears, red deer, foxes, dogs, badgers, grizzle and brown bears, &c Some time after the delivery of the lecture the members of the Club made an excursion to this interesting cave, which was explored for a distance of a hundred feet, and to a vertical depth of thirty feet The visitors saw many stalactites and stalagmites in course of formation, and the osseous remains of animals, including some now extinct Mr Jones pointed out the former location of several human skeletons.

MR. J W TOURNEY contributes to *Science* (November 11) an excellent paper on cliff and cave dwellings in Central Arizona He refers especially to dwellings in cliffs rising a hundred feet or more above Beaver Creek, which flows into the Verde river In the perpendicular walls of one of these cliffs is a well preserved ruin known as Montezuma's castle It is midway between the rim of the cliff and the bed of the stream, and is neither house nor cave, but a combination of the two Not accessible from the summit of the cliff, it can only be reached from below, and even here not without the use of a ladder, which, if short, the climber must pull up from one ledge to another in making the ascent. The entire front is of artificial walls built of large, flat pieces of limestone, with openings here and there for doors and windows The rooms are small, only about five feet to the ceiling Generally a small opening two or three feet in diameter connects one room with another, and a small orifice in the ceiling gives access to the room above. The openings in the ceilings are never directly under one another, so that any one who might stumble could only fall the height of one story The floors are mostly of flat stones supported on timber cut from the surrounding mountains Many of the timbers are still sound The rooms all show considerable skill in their construction Those in the rear are dark, dungeon-like caves hollowed from the solid rock, and are now the abode of thousands of bats, which fly about in great numbers when disturbed by visitors A few miles above Montezuma's castle, on the opposite bank of the creek, a conspicuous cone-like mountain rises a few hundred feet above the surrounding country The summit is a narrow rim enclosing a crater some three hundred feet in diameter and with nearly perpendicular walls Standing on the rim one can look down a hundred feet upon the dark-blue water of a small lake in the bosom of the mountain The lake, a hundred yards in diameter and of unknown depth, is known as Montezuma's well In the steep sides of the crater are a number of caves, which at one time were the abode of man A few are natural, but the greater number are the result of human effort The rim is crowned with the fallen walls of an ancient ruin more than a hundred feet long Far down the mountain side, below the level of the water in the crater, the outlet of the well flows from between an opening in the rocks This stream is large and constant, and at present is used to irrigate a ranch in the valley below Ages ago the builders of caves and castles utilized this same stream to irrigate portions of the neighbouring rich valley

THE fourth volume of "Reports from the Laboratory of the Royal College of Physicians, Edinburgh," edited by J B. Tuke and D Noel Paton, has just been published The work completed in the Laboratory during the past year was so large that an account of the whole of it could not be included in the present volume

A LARGE dirigible balloon is being constructed (*La Nature* informs us) at the military balloon works at Chalais-Meudon, under the direction of Commandant Renard It will be similar in form to the *La France* of 1884-5, but longer, measuring about 230 feet in length and 43 feet in its greatest diameter By a new arrangement of motor it is expected to be able to make headway against air currents not exceeding 40 feet per second (or 28 miles an hour) The motor is not fully described, but it will act either with gasoline or the gas of the balloon, giving an effective force of 45 horse-power on the shaft The total weight of machinery, with supply of gasoline, &c, will be about 30 kilogrammes (or 66 lbs) per horse power Previously it has not been possible to make petroleum motors with a less weight than 150 to 200 kilogrammes per horse-power The screw will be in front, and a large rudder behind, the former will make about 200 turns per minute. The first experiments with this balloon are to be made in the early spring

DR. HEYDWEILER, of Würzburg, has constructed a new mirror electrometer for high potentials (*Zeitschr fur Instr*). It is a kind of torsion-balance with bifilar suspension, the charged bodies being a sphere and a ring The attraction between the two, when at different potentials, is zero when the sphere is at the centre of the ring, and also when it is infinitely removed Hence at some intermediate distance it is a maximum In the instrument as constructed there are two spheres of 2 cm diameter attached to the ends of a conducting bar bent in the form of an S The combination is suspended in a horizontal plane by two brass wires 0·1 mm. thick attached to the middle of the bar Two brass rings 10 cm. across are fixed in a vertical position such that the spheres can be made to coincide

with their centres In the zero position the spheres are at a distance of 3 1cm, this being a little less than the distance of maximum attraction The deflections are indicated by those of a mirror carried by a thin glass rod attached to the curved arm below, and the motion is damped by a vane immersed in some vegetable oil The tangents of the angle of deflection are proportional to the differences of potential to within 0 9 per cent., between the scale readings 0 05 and 0 4 The instrument is best adapted to potentials ranging from 6000 to 60,000 volts, but with potentials above 35,000 it is best to immerse it entirely in oil

AN account of a series of experiments to determine the temperature of the flame of water-gas is given by Mr E Blass, of Essen, in *Stahl und Eisen* The instruments employed were Wyborgh's air pyrometer, Chatelier's electric pyrometer, Hartmann and Braun's telephonic pyrometer, and others by Siemens, Seeger, and Ducretel It was found that Chatelier's formula for the variation of the specific heat of water vapour and other gases at high temperatures was practically reliable The temperatures of combustion were taken for various proportions of air and gas, beginning with a large excess of the latter With 0 18 cubic metres of air to one of gas, the temperature was 425° C Calculated according to the old formula this would have been 521 Allowing for variation of specific heat, the theoretical value becomes 409 For 0 714 of air, the temperature was 1170, for 4 18 it was 1218, for 9 79 it was 655, and for the proportion of air just sufficient for combustion the flame temperature was 1169°

A NEW "shortened telescope," constructed by Dr R Steinheil, is described in the *Zeitschr fur Instr* for November The principle resembles that adopted by Dallmeyer and Dr A Steinheil in their telephotographic objectives A negative system is introduced between the object-glass and the eye piece, thus increasing its equivalent focal length If a be the focal length of the objective by itself, r its distance from the negative lens, and the magnification m times that produced without the negative lens, the total length of the tube is given by $l = r + m\,(a - r)$ In a telescope actually constructed on this system, the object-glass had a focal length of 16 2 cm Its distance from the nearest surface of the negative lens was 12 cm, the equivalent focal length 60 8 cm, and the total length 27 8 cm Hence the magnification was 3 75 times that obtained by using the objective alone In this case, then, a magnification of 22 diameters was obtained with an effective aperture of 4 cm, a total length of 27 8 cm, and a one inch eye piece If the same magnification and illumination had to be obtained by a long-focus objective, the length would have to be 6. 8 cm Thus the length is reduced by more than one half without the usual disadvantages of short telescopes and eye-pieces of high power

ACCORDING to a writer in the *Pioneer Mail* of Allahabad, the thatch on Burmese houses gives a tempting shelter to snakes, especially during the rains, and many of the occupants of the houses would be surprised if they knew the number of snakes that share the shelter of their roof on a rainy night One night an officer was wakened up by a noise in his room, and by the light of a lighted wick, floating in a tumbler of oil, he made out that two combatants were disputing the possession of the small space in the centre of the bedroom The belligerents turned out to be a snake and a rat, that somehow had jostled against each other in the tiny tenement

A VALUABLE report on the geology of north-eastern Alabama and adjacent portions o Georgia and Tennessee, by C Willard Hayes, has been published as a Bulletin of the U.S Geological Survey Mr. Hayes explains that in writing the report he has tried to keep it as free as possible from technical terms, and, without sacrificing scientific accuracy, to present the facts in such a way as to make them intelligible to the largest possible number of readers in the region under consideration Many details which would be of interest to the geologist have been purposely omitted, and only those which were considered essential are given It is expected that the atlas sheets covering this region will shortly be published by the U S Geological Survey, and supply the details to those specially interested which are omitted from the report

A SECOND edition of Prof Oliver J Lodge's "Modern Views of Electricity" has been published by Messrs Macmillan and Co A new chapter on recent progress has been added

A VOLUME on "The Pharmacy and Poison Laws of the United Kingdom" has been issued from the office of *The Chemist and Druggist* It contains also a brief account of the pharmacy laws in force in Australasia, Canada, and Cape Colony

MR CHARLES E MUNROE, Torpedo Station, Newport, Rhode Island, U.S A, has completed the manuscript of the second part of his index to the literature of explosives The first part was issued in 1886 The second will be issued in pamphlet form if an adequate number of subscriptions is obtained

MESSRS FRIEDLANDER AND SON, Berlin, send us the latest of their lists of the books which they offer for sale It is a list of works relating to ornithology

PENTA IODIDE and penta-bromide of cæsium, together with several other penta-halogen compounds of the metals of the alkalies containing mixed halogens, have been isolated by Messrs Wells and Wheeler, and are described by them in the current number of the *Zeitschrift für Anorganische Chemie* Cæsium penta iodide, CsI_5, is obtained in an impure form when the crystals of the tri-iodide of cæsium, CsI_3, previously obtained by Prof Wells and described in our note of February last, vol. xlv p 325, is treated with hot water, or when solid iodine is treated with a hot solution of cæsium iodide Either of these processes produce it in the form of a black liquid, which solidifies in the neighbourhood of 73° The tri-iodide of cæsium, moreover, which is only sparingly soluble in alcohol, is found to be much more readily soluble when a quantity of iodine, corresponding to two atoms for each molecule of the tri-iodide, is added. Upon cooling, crystals of the penta-iodide of cæsium are deposited Remarkably well-formed crystals are obtained upon evaporation of a more dilute solution over oil of vitriol The crystals are black and the faces extremely brilliant, they sometimes attain a diameter of a centimetre They belong to the triclinic system according to Prof Penfield, by whom they have been measured They are at once distinguished from crystals of iodine by their form and brittleness. They melt at about 73° When exposed to the air they lose iodine about as rapidly as crystals of free iodine These crystals are anhydrous, and yield analytical numbers agreeing with the formula CsI_5. The penta-bromide of cæsium may be similarly obtained by agitating a concentrated solution of cæsium bromide with a large excess of bromine. When such a mixture is allowed to stand at a low temperature the excess of bromine slowly evaporates and the penta-bromide separates in the form of a dark red solid substance Cæsium penta-bromide $CsBr_5$, is a very unstable substance, losing bromine rapidly at the ordinary temperature. Anothe interesting compound is cæsium tetrachloriodide, $CsCl_4I$, which was obtained by dissolving forty grams of cæsium chloride in mixture of six hundred cubic centimetres of water and two hundred cubic centimetres of concentrated hydrochloric acid, adding

thirty grams of iodine, and then saturating the liquid with chlorine gas The temperature was raised slightly during the operation, and upon subsequent cooling the compound $CsCl_4I$ was deposited in the form of pale orange-coloured prismatic crystals belonging to the monoclinic system The compound is only slightly soluble in water, but, with a little loss due to decomposition, may be recrystallized from that liquid It is, however, quite stable in the air, and only decomposes upon heating, thereby producing the tri-halogen compound, $CsCl_2I$, fusing at 238°, the melting-point of this latter compound A similar compound, containing rubidium instead of cæsium, $RbCl_4I$, may be obtained in like manner in large orange-coloured tabular crystals, likewise belonging to the monoclinic system, but of different habitus to the crystals of the cæsium compound An analogous compound containing potassium, KCl_4I, was prepared so long ago as the year 1839, by Filhol Messrs Wells and Wheeler finally describe sodium and lithium salts of this description, both of which, however, contain water of crystallization They are represented by the formulæ $NaCl_4I\ 2H_2O$ and $LiCl_4I\ 4H_2O$ Both crystallize well, the former in rhombic prisms, the latter, however, is so extremely deliquescent that measurements of the crystals have not been obtained

THE additions to the Zoological Society's Gardens during the past week include two Common Marmosets (*Hapale jacchus*) from South-east Brazil, presented by Mrs Comolli, an Otter (*Lutra vulgaris*) British, presented by Mr Frederick Collier, a Black-backed Jackal (*Canis mesomelas*, ♂v) from South Africa, presented by Miss Thornton, a Common Jackal (*Canis aureus*, ♀) from Fao, Persian Gulf, presented by Mr W D Cumming, C M Z S, two Short-headed Phalangers (*Belideus breviceps*, ♂ ♀) from Australia, presented by Capt S M Orr, a —— Lemur (*Lemur* ——) from Madagascar, six Crab eating Opossums (*Didelphys cancrivorus*), four Ypecha Rails (*Aramides ypecha*) from South America, a Green cheeked Amazon (*Chrysotis viridigenalis*) from Columbia, a Yellow-cheeked Amazon (*Chrysotis autumnalis*) from Honduras, purchased, a Nilotic Monitor (*Varanus niloticus*) from Africa, received in exchange, two Shaw's Gerbilles (*Gerbillus shawi*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

COMET HOLMES (NOVEMBER 6, 1892) —The elements and ephemeris of this comet have been the subject of much computation during the present month The first result obtained gave a place resembling in many particulars that of the long-sought for Biela comet, but owing to an error in one of the observations, the corrected elements stated otherwise The current number of *Astronomische Nachrichten* (No 3129) gives four different systems of elements which have as yet been deduced, and it is quite worth while to produce them here, showing also the difference between the observed and reduced places for each in particular

Elements, Berlin M T.

	1892	1892	1892	1892
T =	Feb. 28 362	Mar 19 630	May 6 301	June 6·841

Mean place (O – R) dβ	+ 0 86	+ 0 84	+ 0 58	+ 0 41

The latest information about the elements is that which has originated from Prof. Kreutz, who has found *elliptic* elements for the comet, he also says that the elements indicate that perturbations have taken place on account of the comet's proximity to the planet Jupiter. The elements are reduced from the three places observed on November 9, 13, and 17, and are as follows —

Epoch 1892 Nov 17 5 M T Berlin.

M =	22 18 37 1
ω =	13 37 49 0 ⎫
☊ =	331 31 3 7 ⎬ 1892 0

μ =	500″ 407
log u =	0 567123
U =	7 09 years

Further observations of this comet are reported (*Comptes rendus*, No 21) At Algiers, MM Trépied, Rambaud, and Sy found its position on November 15, at 8h 53m 41s, Algiers mean time, to be App R A 0h 43m 22 28s App Decl +37° 43′ 3″ 9 The corresponding values found at Lyon by M. G Le Cadet at 8h 47m 33s, Paris mean time, were App R A 0h 43m 22 72s App Decl + 37° 43′ 5″·9 The comet presented a bright nebulosity in the form of an elliptic segment with its axis directed in the position angle 150°, its length and breadth both being 10′ The northern edge appeared rounded and well defined At the focus of the ellipse a condensation could be distinguished, about 20″ broad, with a prolongation inclined to the axis of the ellipse An attempt at calculating the elements of the orbit has been made by M Schulhof The slow motion of the comet renders this task very difficult Among the various systems of elements tentatively fixed there is only one which fairly agrees with all observations In this the excentricity is as small as 0 355386, so that it will probably be possible to follow the comet throughout its orbit with the most powerful instruments The other elements thus determined are π = 0° 0′ 39″ 1, ☊ = 328° 32′ 40″ 7, i = 20° 26′ 46″ 8, and log g = 0 360966

At Bordeaux, M F Courty succeeded in photographing the brighter portions of the comet on November 13, with one hour's exposure Another photograph, taken by MM Paul and Prosper Henry at Paris, was presented to the Academy by M Tisserand It was obtained on November 14, with the chart photographic equatorial The exposure lasted two hours It is a very fine photograph, showing a well defined and nearly circular contour The nucleus is bright, excentric and lengthened out Several stars can be seen through it There is no tail except the lengthening of the nucleus, which does not extend beyond the limits of the nebulosity

A BRIGHT COMET —A telegram from Kiel states that Mr W R Brooks has discovered a bright comet As determined at Cambridge, U S, its place was, on November 21, at 16h 44 6m Cambridge M T

R A 12h 59m. 15 6s
Decl + 13° 50′ 27″ 0
Daily motion + 1m 32s, and + 25′ respectively

Another telegram, also from Kiel, gives the position, as obtained at Vienna on November 24, at 15h 49 7m. (Vienna M T), as

R A 13h 3m 6 4s
Decl + 15° 0′ 36″

ASTRONOMICAL INSTRUMENTS UP TO DATE.—We have received a circular signed by Dr. L Ambronn, of the Gottingen Observatory, and Herr Julius Springer, publisher in Berlin, setting forth the contents of a work which they propose to publish with regard to the general principles, constructions, and methods of using astronomical instruments in general Such a book, of course, to be of the greatest value to science, must be completely done, but any one who is acquainted with the compiler and publisher mentioned above will be sure that each will do his share thoroughly and honestly. In constructing such a compendium of instruments as this is proposed to be, we might say it would be impossible for one man to do it alone, for the present state of the *feintechnik* has reached such a high pitch and the branches of astronomy are so numerous, that such an undertaking would simply be out of question. The object of this circular, besides stating the lines on which the work will be written, is to request the co-operation of all observatories. Astronomical science, especially the theoretical side, owes much, as we all know, to German workers, so that we can rely on a good response being given to this request. What is

asked is that descriptions, together with drawings or photographs not only of typical instruments but of the important parts of them, should be sent. Technical drawings also are requested, if obtainable, and these very probably could be obtained from the makers of the instruments in question. Of course it is not required that each observatory should send say a description, &c., of the transit instrument there in use, but it is hoped that any instrument of peculiar construction or special merit should be referred to. It is needless to add that all drawings, &c., if requested, will be returned with as little delay as possible, and the undersigners of the circular thank in advance all those who respond towards the completion of this undertaking. The address to which the drawings, &c., may be sent is as follows:—Dr. L. Ambronn, Gottingen, Kgl. Sternwarte.

MOTION OF β PERSEI.—*Astronomical Journal*, No. 277, contains a short note calling the attention of transit observers to the importance of observation of this variable, to confirm the irregularity in its proper motion. At the present time Algol and his neighbouring stars are conveniently situated, and it is hoped that the following list of stars will be added to working lists generally where their observation is not inconsistent with other work. The places are for the year 1875:—

	R.A. h	m	s	Decl. °	′
γ Andromedæ	1	56	14	41	43·7
β Trianguli	2	2	7	34	23·7
θ Persei	2	35	40	48	41·9
41 Arietis	2	42	38	26	44·6
γ Persei	2	55	45	53	0·9
ϕ Persei	2	57	10	38	21·3
β Persei	3	0	2	40	28·3
α Persei	3	15	24	49	24·9
δ Persei	3	34	2	47	23·1
ν Persei	3	36	42	42	10·9
η Tauri	3	40	3	23	43·0
ζ Persei	3	46	17	31	30·6
ϵ Persei	3	49	28	39	38·8
ξ Persei	3	50	51	35	25·8

PROPER MOTIONS.—M. Deslandres, in *Comptes rendus* of November 14, communicates the recent work he has been carrying out with regard to the spectroscopic determinations of proper motions. The first part contains a description of the apparatus employed, showing how he has completely altered one instrument specially for this work. During the ten months of the year he has obtained several proofs of stars susceptible of furnishing radial velocity. The following are among some of the important methods of procedure:—(1) The luminous "faisceaux" of the star and of the source of light have the same aperture, and are thus as identical as possible, a condition necessary to the absolute measure of displacements. (2) The displacements of spectra is measured not only with the Hy line of hydrogen, but with all the hydrogen, calcium, and iron lines. (3) The large surface of the mirror renders the possibility of measuring the velocities of 250 stars. Some of the results already obtained show that the work, when finished, will be of a very reliable and accurate kind. For instance, the velocity of Venus has been obtained instrumentally as 15 kilometers, while that calculated amounted to 13·55 k.m. The velocity of α Aurigæ on February 5, employing 30 lines of comparison, came out as 43·5 k.m., and the velocities of the components of β Aurigæ, a spectroscopic double, were obtained on the same day as − 84·5 k.m. and + 97 k.m.

GEOGRAPHICAL NOTES

THE measurement of an arc of the meridian between Dunkirk and the Spanish frontier, which has recently been completed with the highest precision by the French Government, shows that the measurement by Delambre and Méchain in determining the length of the metre was 126·6 feet, or $\frac{1}{10000}$th too short. The new measurement accords very closely indeed with the value as deduced from Clarke's ellipsoid.

A NEW weekly paper devoted to African geography, under the title of Kettler's *Afrikanische Nachrichten*, was started at Weimar in July last, with the object of collecting and publishing the most recent information on all matters connected with Africa and the Africans. An ingenious feature is that of giving a sketch map of parts of Africa, with a small section of a map of some well-known part of Germany on the same scale below it, for the purpose of ready comparison of distances.

MR. AND MRS. THEODORE BENT have arranged to spend the winter in Abyssinia studying the ancient monuments of Axum. They will leave this country about the middle of December. We understand that Mr. Bent would welcome a scientific man who might wish to work at any of the natural conditions of eastern Abyssinia, and take advantage of the arrangements which have been made for the safety and comfort of the party. It would, of course, be necessary for such a companion to pay his own expenses and provide his own outfit.

A SPECIAL general meeting of the Royal Geographical Society was held on Monday afternoon to consider some alterations in the rules, recently decided on by the Council. It was agreed to raise the entrance fee to the Society from £3 to £5, and to augment the life composition accordingly, relief being, however, granted by a diminution of the commutation fee to members of long standing. Other changes were made to bring the laws into harmony with the present practice of the Society in several minor matters. The meeting also passed a resolution associating itself with the act of the Council in no longer withholding the Fellowship of the Society from women.

MR. JOSEPH THOMSON'S JOURNEY TO LAKE BANGWEOLO

MR. JOSEPH THOMSON read a paper on his expedition to Lake Bangweolo in 1890–91 to the Royal Geographical meeting on Monday night. The paper was not only of a thoroughly scientific character, but also a model of literary grace, Mr. Thomson having the trained eye which enables him to detect and throw into prominence the really important features. The expedition went up the Zambesi by way of the Kwakwa creek, encountering considerable hostility and obstruction from the Portuguese authorities on the way. Mr. Thomson speaks warmly of the great work done by the Scottish missionaries in the Blantyre and Nyassa districts. Under the kind but firm control of the missionaries the warlike Angoni tribes came in thousands to cultivate the fields, which formerly they visited only for plunder, and for the first time in all his African travels Mr. Thomson found a spot where the advent of the white man was an unmitigated blessing to the natives.

Barometric observations made while waiting for porters on the western coast of Lake Nyassa made the elevation of the lake 1430 feet, a somewhat lower result than was formerly arrived at. On August 23, 1890, the expedition, comprising Mr. Grant, Mr. Charles Wilson, and 153 porters, started from Kotakota and struck westward through unmapped country, a rough and sparsely wooded plateau with little running water. The route lay along a strip of debateable ground, inhabited by an excitable, warlike tribe, and raided equally by Mwasi's people from the north and Mpeseni's from the south. Great tact was required to avoid bloodshed, but the expedition passed safely. Then crossing the fine fertile plain of the Loangwa river, they passed over and climbed the steep Muchinga mountains to the high plateau beyond. So far the rocks had been metamorphic, with intruded masses of granite, overlaid in the valley by sandstones, shales, and marls. At one place great fossil-tree trunks were found. The Loangwa-Kafue plateau was magnificent country, glorious with the tints of early spring on the stunted trees which formed a scraggy forest over most of the surface. But no sign could be seen of the Lokinga mountains, nor was any word heard from the natives of that range so conspicuous on the maps; but on the watershed of the plateau, 5000 feet above the sea, rose the Vimbe hills in a series of isolated domes, perhaps rising 1000 feet higher. A new lake, thirty square miles in area, was found in a dip of the plateau, and named after the Moirs. Then troubles began. Small-pox broke out amongst the porters, and when Chitambo's was reached no trace could be found of the lake, on the margin of which it was supposed to stand. While the white members of the expedition were attending to their sick followers some of the healthy Swahilis marched to Old Chitambo's (which is not in Ilala but Kalinde), now deserted, and twenty miles distant from the present village, finding the tree under which the heart of Livingstone was buried still standing, and the inscription on it legible. In the dry season the Chambeze does not enter Lake Bangweolo at all, but flows direct across the marsh to the Luapula, but in the wet season

the whole of the great marsh to the south is flooded up to Chitambo The level at that time was made out to be 3750 feet, about 250 feet lower than Livingstone's estimate After a rest for recovering health the expedition followed the Luapula eastward through fertile country, and leaving it where the curve from the north occurs, struck across for the Kafue, but small-pox reappeared, the land was ravaged by half caste Portuguese slave-raiders, Mr Thomson himself fell ill, and the course had to be changed to the south with the hope of turning west again But matters got worse instead of better, and after touching the borders of Manica, a return had to be made to Lake Nyassa, along the southern margin of the plateau, through deep valleys, and climbing the steep slopes of the Muchinga Mountains, here separated by the great parallel valley of the Lukosashe from the plateau. All the way the land was seen to be of immense possibilities for cultivation, but neglected, and inhabited by a wretched people governed by Mpeseni, himself the vilest of them all Kotakota on the lake was reached again on January 4th, 1891, after a total journey of 1200 miles, which resulted in many important rectifications of position and much information as to the future possibilities of the plateaux

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —Dr Hobson, late deputy Lowndean Professor, has been elected a representative of the Mathematical Board on the General Board of Studies.

Plans for a handsome building to serve as the Sedgwick Memorial Museum of Geology have been submitted to the Senate, the estimated cost being £26,000 Four members of the Syndicate appointed to prepare the plans dissent from the report of the majority, chiefly on the ground that the internal arrangements are unsatisfactory, and that the cost, initial and annual, of the proposed building will be excessive The divergent views held on the subject will be discussed by the Senate on Saturday, December 3

The Senate have agreed to confer on Sir R S Ball, the new Lowndean Professor, the complete degree of M A, *honoris causa.*

SOCIETIES AND ACADEMIES

LONDON

Physical Society, November 11 —Mr Walter Baily, M A, Vice-President, in the chair —The discussion on Mr Williams's paper, the dimensions of physical quantities, was resumed by Dr Burton He remarked that the idea that so called "specific quantities," such as specific gravity, are pure numbers was an erroneous one, and liable to lead to difficulties The specific gravity of a substance was of the nature of density, and was only a simple number on the convention that the density of water was taken as unity If dimensions be given to specific quantities their interpretation would, he thought, be easy when the rational dimensional formulæ were found Referring to Prof Fitzgerald's comments, he said, although the contention that all energy is ultimately kinetic could not be gainsaid, the distinction commonly drawn between kinetic and potential energy involved nothing contrary to this view, and was useful and convenient in many cases. As to the dimensions of μ and k he was inclined to favour Mr Williams's views, for several considerations suggest that the two capacities of the medium are essentially different Arguments to show that μ was probably absolutely constant in the ether, whilst k might be variable, were brought forward Of the two systems of dimensions for μ and k suggested by Mr Williams, that which made μ a density seemed preferable —Prof A Lodge said he was greatly interested in propagating the idea that physical quantities are concrete, and therefore welcomed Mr Williams's paper. He thought it desirable to keep some names for abstract numbers, and "specific gravity" should be one If another name involving dimensions was required "specific weight," or "weight per unit volume," might be used Speaking of the dimensions of the various terms of an equation he did not think it was usually recognized that in ordinary algebra or Cartesian geometry the principle of directed terms was rigidly adhered to, for if directed at all every term of such an equation was directed along the same line In this respect ordinary algebra was more rigid than vector algebra. Even if circular functions were involved, as in polar co-ordinates, they had the effect of making the directions of the terms the same. Other instances of problems bringing out the same fact were mentioned Mr Boys thought Mr Madden had been arguing in a circle when he spoke of the astronomical unit of mass, and deduced the dimensions of mass as L^3/T^2 from the equation $MLT^{-2} = M^2/L^2$, for it was quite impossible that this equation could be true unless γ, the gravitation constant, was introduced on the right-hand side Mr Williams's method was quite the reverse, for he maintained that unless k and μ were introduced in the dimensions of electric and magnetic quantities, their dimensional formulæ could not indicate the true nature of those quantities, and hence were open to objection Mr W Baily, whilst agreeing with Mr Williams on most essential points, thought the total omission of L from dimensional formulæ made the expressions more complicated and less symmetrical For example, such expressions as XY/Z, X^2 and XYZ, which respectively represent undirected length, area, and volume, might with advantage be written L, L^2, and L^3 respectively The restriction of the dimensions of μ and k to those which give interpretable dimensional formulæ for electrical and magnetic quantities seemed scarcely justified Both the systems proposed could not be right, and he thought it would be more in accordance with our present want of knowledge, if a quantity U of unknown dimensions were introduced such that μ or $k = U^2$ density and k^{-1} or $\mu^{-1} = U^2$ rigidity This would keep in view the fact that the absolute dimensions of quantities involving U were unknown A list of the dimensions of the various quantities based on this arrangement was given Mr Swinburne, referring to the conventional nature of many units, said great differences exist between the ideas held by different persons about such units Starting with the convention that unlike quantities could be multiplied together, he might have six ampères flowing in an electric circuit under a pressure of ten volts, and he might say he had sixty volt-amperes The term "volt ampère" could be regarded as indicating that the sixty was the numerical result of multiplying a number of volts by a number of ampères, or on the other hand it might be understood as a new unit, a *watt*, compounded of a volt and an ampère Before Prof Rucker's paper on suppressed dimensions was published, an electrician might have suggested measuring the length of a bench by sending an alternating current through it and determining its self induction, which he regarded as a length Prof Rucker, however, would say that this could not give the right result, for μ must be taken into account He was inclined to think that dimensions were liable to mislead Referring to scientific writers as authorities, he said Maxwell had been careless in some cases, for he had sometimes given dimensional formulæ as zero, which really ought to have been $L^0 M^0 T^0$, or unity In French text-books the errors had been corrected Mr Williams, in reply to Mr Madden's remarks about self-induction being a length, pointed out that the subject might be looked at in two different ways, depending on whether one thinks of the *standard* of self-induction as the practical standard of measurement, or the *unit* of self induction as a physical quantity In the former case the *standard* was a length, but in the latter the *unit* was a quantity of the same *species* as self-induction, the nature of which was as yet unknown If its dynamical nature was known, then the absolute dimensions of all other magnetic and electric quantities would also be determined In answer to Prof. Fitzgerald's remarks he said it was hardly likely that he should be unacquainted with the common view that kinetic and potential energies were ultimately quantities of the same kind, for it was a view with which he was quite familiar The fact that they have the same dimensions was sufficient to show their identity, and the idea that all energy is ultimately kinetic was fundamental to his paper. This, however, did not imply that electrification and magnetization are of necessity the same, and the suggestion that they may be the same was only one of several "probable suggestions," all of which were entitled to consideration. His chief reason for regarding Prof Fitzgerald's suggestion as probably incorrect was that it led to a system of dimensional formulæ incapable of rational mechanical interpretation, and containing fractional powers of the fundamental units. Prof. Fitzgerald's system would make resistance an abstract number, and μ and k directed quantities, whereas the former was a concrete quantity and the two latter must be scalar in isotropic media. If he (Mr. Williams) had erred in treating electrification and magnetization as different phenomena he could only plead that he had

done nothing more than follow such authorities as Lord Kelvin, Dr Lodge, and Mr O Heaviside in the matter —The discussion on Mr Sutherland's paper, on the laws of molecular force, was reopened by Prof Perry reading a communication from the President, Prof Fitzgerald He objected to discontinuous theories, especially when Clausius had given a continuous formulæ much more accurate over a very long range than Mr Sutherland's discontinuous ones The introduction of Brownian motions without carefully estimating the rates required and energy represented, and without giving any dynamical explanation of their existence, was not satisfactory It would, he said, be most interesting if Mr Sutherland would calculate the law of variation of temperature with height of a column of convectionless gas, under conduction alone (for Maxwell thought the inverse fifth power law of molecular attraction was the only one that gave uniformity of temperature under these conditions), and if necessary make tests with solid bars Referring to the statement that molecular attraction at one cm was comparable with gravitation at the same distance, he thought Mr Boys would question this, and he suggested an *experimentum crucis* of the inverse fourth power law Both the inverse fourth and inverse fifth power laws, assumed symmetry which did not exist He also took exception to other parts of the paper Dr Gladstone, referring to the relative dynic and refraction equivalents given in Table XXVIII of the paper, said he thought it interesting to make a similar comparison between dynic and dispersion and magnetic rotation equivalents The result as exhibited in a complete table showed a certain proportionality between the four columns but the differences were beyond the limits of experimental error Mr Sutherland, however, sometimes reckoned the dynic equivalent of hydrogen as 0 215, and at other times looked upon it as negligible The analogies between the optical equivalents did not depend on the proportionality of the numbers so much as upon the fact that the refraction, dispersion, and magnetic rotation equivalents of a compound was the sum of the corresponding equivalents of its constituent atoms, modified to some extent by the way in which they were combined Whilst a somewhat similar relation held true for the dynic equivalents, the effect of "double linking" of carbon atoms, so evident in the optical properties, was scarcely perceptible The result of calculating the constants from Ml instead of from M^2l was next discussed, the effect of which was to quite upset the proportionality before noticeable Mr S H Burbury said that on referring to the author's original paper, on which the present one was based, he found that a uniform distribution of molecules was assumed. On this supposition the demonstrations given were quite correct, and the potential was a maximum If, however, the molecules were in motion the average potential must be less than the maximum, and the deductions in the present paper being based on wrong assumptions were liable to error Prof Ramsay remarked that many statements in the paper, on the subject of critical points, were very doubtful Separate equations for the different states of matter were not satisfactory, neither was the artificial division of substance into five classes The predicted differences in the critical points due to capillarity, had not been found to exist Speaking of the virial equation, he said that hitherto R had been taken as constant Considerations he had recently made led him to believe that R was not constant The whole question should be reconsidered regarding R as a variable Mr Macfarlane Gray said he had been working at subjects similar to those dealt with in Mr Sutherland's paper, but from an opposite point of view, no attraction being supposed to exist between molecules In the theoretical treatment of steam he found that no arbitrary constants were required, for all could be determined thermo-dynamically The calculated results were in perfect accord with M Cailletet's exhaustive experiments except at very high pressures, and even here, the theoretical volume was the mean between those obtained experimentally by Cailletet and Battelli respectively Prof. Herschel pointed out that Villarçeau had discussed the equation of the virial, where the chemical and mechanical energies were not supposed to balance each other Mr. Sutherland's paper all turns on the existence of such a balance, and he (Prof. Herschel) could not understand why this balancing was necessary. The discussion was then closed, and the meeting adjourned.

Geological Society, November 9.—W H. Hudleston, F R.S., President, in the chair.—The following communications were read:—A sketch of the geology of the iron, gold, and copper districts of Michigan, by Prof M. E. Wadsworth. After an enumeration of the divisions of the azoic and palæozoic systems of the upper and lower peninsulas of Michigan, the author describes the mechanically and chemically formed azoic rocks, and those produced by igneous agency, adding a table which shows his scheme of classification of rocks, and explaining it The divisions of the azoic system are then described in order, beginning with the oldest—the cascade formation, which consists of gneissose granites or gneisses, basic eruptives and schists, jaspilites and associated iron ores, and granites The rock of the succeeding republic formation are given as nearly as possible in the order of their ages, commencing with the oldest —Conglomerate, breccia and conglomeratic schist, quartzite, dolomite, jaspilite and associated iron ores, argillite and schist, granite and felsite, diabase, diorite and porodite, and porphyrite The author gives a full account of the character, composition, and mode of occurrence of jaspilite, and discusses the origin of this rock and its associated ores, which he at one time considered eruptive, but new evidence discovered by the State Survey and the United States Survey leads him to believe that he will have to abandon that view entirely In the newest azoic formation, the Holyoke formation, the following rocks are met with —Conglomerate, breccia and conglomeratic schist, quartzite, dolomite, argillite, greywacke and schist, granite and felsite (?), diabase, diorite, porodite, peridotite, serpentine, and melaphyre or picrite The conglomerates of the Holyoke formation contain numerous pebbles of the jaspilites of the underlying republic formation, a description of the Holyoke rocks is given, and special points in connexion with them are discussed. The author next treats of the chemical deposits of the azoic system, gives a provisional scheme of classification of ores, and discusses the origin of ore deposits. The rocks of the palæozoic system are next described, and it is maintained that the eastern sandstone of lower silurian age underlies the copper-bearing or Keweenawan rocks The veins and copper deposits are described in detail, and the paper concludes with some miscellaneous analyses and descriptions, as well as a list of minerals found in Michigan After the reading of this paper, the President noted that it presented three sets of questions of much importance, viz., those bearing on the archæan rocks, the iron deposits and jaspilites, and the copper and gold deposits respectively As regards the classification of the archæan rocks, some might wonder what the terms used by the author meant. The words laurentian and huronian used in Canada seemed not to be tolerated in Michigan The officers of the United States Geological Survey have described all the archæan formations noticed by the author, the cascade as the fundamental complex, the republic as the lower marquette, and the Holyoke as the upper marquette Was each State of the Union going to divide these archæan rocks after its own fashion? With regard to the iron rocks, he would observe that the author, after enumerating all the views in favour of their volcanic origin, now admitted that he was wrong, and that Irving and others were correct The most important question was how the iron ores were really formed, and to this it was difficult to find a complete answer in the paper Sir Archibald Geikie remarked that it was hardly possible to criticize a voluminous paper of this nature, in the reading of which much of the detailed statement of facts was necessarily omitted One of its most interesting points related to the nature and classification of the rocks intermediate between the base of the Cambrian system and the oldest or fundamental gneisses. The plan which Prof. Wadsworth followed of adopting local names for the several subdivisions of the series in each region was no doubt in the meantime of advantage, until some method of correlation and identification from region to region could be discovered. But it unavoidably led to temporary confusion, for the same rock group might turn out to have received many different names. He thought it would be of service if geologists could agree upon some general term which would denote the whole of the sedimentary groups or systems which intervene between the old gneisses and the *Olenellus*-zone Various names had been proposed, such as azoic, eozoic, proterozoic, algonkian, to each of which some objection may be raised. The existence of a number of very thick systems of sedimentary deposits between the base of the Cambrian formation and the gneisses was now well established in this country and in North America. In the upper members of this series fossils had been found, and it might eventually be possible to group the rocks by means of palæontological evidence. But in the meantime it would be convenient to class them under one general name which would clearly mark them off from the true archæan gneisses, &c., below them and the palæozoic rocks

above Dr Hicks congratulated Prof. Wadsworth on his important communication, but he strongly objected to the application of the term Silurian, instead of Cambrian, to the lower palæozoic rocks of America. Dr Hicks did not think that the author had proved his case with regard to the Keweenawan rocks, and he was still inclined to believe that they would prove to be, as suggested by other American geologists, of pre-Cambrian age—the apparent superposition being due to over-thrust faults The term eozoic, now that worm tracks have been discovered in the pre Cambrian rocks, is more correct than azoic for the sedimentary rocks of that age. Moreover, other organic remains will certainly be found, for it is inconceivable that ancestors of the forms comprising the rich fauna at the base of the Cambrian should not have been entombed in earlier rocks Mr H Bauerman, considering the three hypotheses as to the origin of the iron ores—namely, dehydration of limonites in sandy beds, transformation from siderite, and the breaking-up of highly ferriferous igneous masses into quartz and hæmatite —thought that the first was the most likely, although there were certainly difficulties in connexion with it which made it desirable that the newer views upon the subject should be presented He was therefore glad that they were likely to have a detailed exposition of the author's views in the journal As regards the origin of the copper deposits, he believed that Dr Wadsworth agreed with the views brought before the society several years since In conclusion, he called attention to the gold deposits, which were of comparatively recent discovery, and interesting from the large number of minerals associated with the auriferous quartz veinstuff Sir Lowthian Bell and Mr Marr also spoke —The gold quartz deposits of Pahang (Malay Peninsula), by H M Becher —The Pambula gold deposits, by F D Power

Zoological Society, November 15 —Dr A Gunther, F R S, Vice President, in the chair —The Secretary read a report on the additions that had been made to the Society's Menagerie during the month of October 1892, and called special attention to a very fine male Ostrich (*Struthio camelus*) presented by Her Majesty the Queen, and to a specimen of what appeared to be a new and undescribed Monkey of the genus *Cercopithecus*, obtained by Dr Moloney at Chindi, on the Lower Zambesi, for which the name *Cercopithecus stairsi* was proposed Attention was also called to the receipt of a series of specimens of mammals, birds, and reptiles, brought by Mr Frank Finn, on his recent return from a zoological expedition to Zanzibar, and received from several correspondents of the Society at Zanzibar and Mombasa.—The Secretary exhibited (on behalf of Mr T Ground) a specimen of the Siberian Pectoral Sandpiper (*Tringa acuminata*) killed in Norfolk —Mr G A Boulenger read a paper describing the remains of an extinct gigantic tortoise from Madagascar (*Testudo grandidieri*, Vaill), based on specimens obtained in caves in South west Madagascar by Mr Last, and transmitted to the British Museum The species was stated to be most nearly allied to *Testudo gigantea* of the Aldabra Islands.—Mr W Bateson and Mr H H Brindley read a paper giving the statistical results of measurements of the horns of certain beetles and of the forcipes of the male earwig It appeared that in some of these cases the males form two groups, "high" and "low", the moderately high and the moderately low being more frequent than the mean form in the same locality It was pointed out that this result was not consistent with the hypothesis of fortuitous variation about one mean form.—A communication was read from Mr O. Thomas containing the description of a new monkey of the genus *Semnopithecus* from Northern Borneo, which he proposed to call *S everetti* after Mr A Everett, its discoverer —Mr G A. Boulenger read a description of a Blennioid fish from Kamtschatka belonging to a new generic form, and proposed to be called *Blenniophidium petropauli* The specimen had been obtained in the harbour of Petropaulovski by Sir George Baden Powell, M P, in September 1891

Royal Meteorological Society, November 16.—Mr A Brewin, Vice-President, in the chair —An interesting paper by Mr. J. Lovel was read on the thunderstorm, cloudburst, and flood at Langtoft, East Yorkshire, July 3, 1892 The author gives an account of the thunderstorm as experienced at Driffield on the evening of this day, the full force of the storm was, however, felt in the wold valleys, which lie to the north and north-west of Driffield, where great quantities of soil and gravel were removed from the hillsides and carried to the lower districts, doing a large amount of damage. Many houses in the lower parts of Driffield were flooded, and a bridge considerably injured The storm was most severe in a basin of valleys close to the village of Langtoft, where three trenches, sixty-eight yards in length and of great width and depth, were scooped out of the solid rock by the force of the water from the cloudburst. From the appearance of the trenches it is probable that there were three waterspouts moving abreast simultaneously This particular locality seems to be favourable for the formation of cloudbursts, as there are records of great floods having previously occurred at Langtoft, notably on April 10, 1657, June, 1857, and June 9, 1888 The author gives, in an appendix, a number of observations made on similar occurrences, together with particulars and opinions as to the cause of such outbursts by several eminent authorities —Mr W H Dines also read a paper, remarks on the measurement of the maximum wind pressure, and description of a new instrument for indicating and recording the maximum For some years the author has been conducting a large number of experiments with various forms of anemometer, and in the early part of the present year recommended the adoption of the tube anemometer for general use, as it appeared to possess numerous advantages The head is simple in construction, and so strong that it is practically indestructible by the most violent hurricane. The recording apparatus can be placed at any reasonable distance from the head, and the connecting pipes may go round several sharp corners without harm The power is conveyed from the head without loss by friction, and hence the instrument may be made sensitive to very low velocities without impairing its ability to resist the most severe gale In the present paper the author describes an arrangement of this form of anemometer which he has devised for indicating very light winds as well as recording the maximum wind pressure

Linnean Society, November 17 —Prof Stewart, President, in the chair —The President having announced a proposal by the council to present a congratulatory address to the Rev Leonard Blomefield (formerly Jenyns) on the occasion of the seventieth anniversary of his election as a Fellow of the Society, and in recognition of his continuous and useful labours as a zoologist, it was moved by Sir Wm Flower and seconded by Dr St George Mivart, that the address be signed and forwarded as proposed This was carried unanimously In moving the resolution, Sir Wm Flower took occasion to sketch the scientific career of Mr Blomefield, who is now in his ninety-third year, and to recapitulate the works of which he is the author under his earlier and better known name of Jenyns The address, which was beautifully illuminated on vellum, was then signed by those present —Mr. George Murray exhibited and made remarks upon a genus of Algæ (*Halicystis*) new to Britain, the species shown being *H ventricosa* from the West Indies, and *H ovalis* from the Clyde Sea area —Mr Buxton Shillitoe exhibited an artificial cluster of the fruit of *Pyrus sorbus*, as put up for ripening by cultivators in Sussex —A paper was then read by the Rev Prof Henslow on a theoretical origin of endogens through an aquatic habit based on the structure of the vegetative organs The lecture, which was very fluently delivered, was profusely illustrated, and drew forth some interesting criticism from Prof Boulger, Messrs Henry Groves, H Goss, and Patrick Geddes, to which Prof Henslow replied.—On behalf of Mr George Lewes, who was unable to be present, a paper was read by Mr W Percy Sladen on the *Buprestidæ* of Japan, upon which some criticism was offered by Mr W F Kirby

Royal Microscopical Society, November 16.—Dr. R Braithwaite in the chair —Mr. T F Smith read a note on the character of markings on the *Podura* scale.—An account of Mr W. West's paper on the freshwater algæ of the English lake district was given by Mr A. W Bennett, who thought it was an exceedingly important contribution to our knowledge of the algæ of that district-Mr F Chapman gave a *résumé* of Pt 3 of his description of the foraminifera of the Gault of Folkestone —Mr. C Haughton Gill read a paper on a fungus internally parasitic in certain diatoms, illustrating his subject with specimens and photomicrographs Mr Bennett said that he had observed structures which might be of a similar character in desmids. He should like to enquire if by the term "spores" Mr. Gill did not mean zoospores? Had he observed them to be possessed of vibratile cilia? And could he form any idea as to how they came to be inside the diatoms? It was possible that they might be transmitted in some way by inheritance, and if so that might account for their great abundance in particular species. Mr. Gill said

that the question how these things got into diatoms was one still under consideration As to the movements of the spores he was not at present perfectly certain that they moved at all more than a very short distance from the orifice of the beak, but he had not yet had time to examine them sufficiently to be able to answer the question as to whether they were ciliated Diatoms were by no means the tightly shut-up boxes which they were supposed to be; they could not live or absorb nutriment unless there was some sort of passage, and he thought there was very likely a means of penetration all over them to admit of the diffusion of fluid throughout — Mr E M Nelson called attention to the fine adjustment of Messrs W Watson's Van Heurck microscope, which he said had been wrongly described as being on Zentmayer's plan, he found that Messrs Watson's adjustment was provided with spring stops, which obviated all the evils complained of in Zentmayer's system, the adjustment-screw was also left-handed, so that the apparent and real motions were made to coincide, which was a great advantage when working with high powers

OXFORD.

University Junior Scientific Club, November 9 — The President, Dr J Lorrain Smith, in the chair — The President gave an exhibit to illustrate the relation of ventilation to respiratory products, after which he called on the Rev F J Smith for his paper on the inductoscript and spark photography The paper, which was illustrated with experiments, and a large and varied selection of lantern slides, dealt with the recent researches of the writer and others in an exhaustive manner It was shown how impressions of coins, &c, could be taken on photographic plates and paper by means of the electric spark, and the various results produced by changes of pressure, &c, in the atmosphere The second part of the paper dealt more with the instantaneous photography produced by the electric spark, and the exhibits included photographs of bullets and other rapidly-moving objects, which had been taken by the reader of the paper — Mr G C Bourne read a paper on Butschli's researches on protoplasm, which was followed by an animated discussion in which Prof Burdon-Sanderson and others took part

CAMBRIDGE

Philosophical Society, November 14. — Prof T McKenny Hughes, President, in the chair — The President exhibited (1) a live tarantula, (2) quartz crystals of unusual form The following communications were made — (1) Preparations were exhibited showing the division of nuclei in the sporangium of a species of *Trichia*, one of the Myxomycetes The nuclei divide throughout the sporangium, with clearly recognizable karyokinetic figures, immediately before the formation of the spores, by J J Lister (2) On the reproduction of *Orbitolites* Mr. H B Brady has described specimens of Orbitolites, which he obtained in Fiji, showing the margin of the disc crowded with young shells Mr Brady's material was worked at in the dry state, and it was at his suggestion that the author collected specimens preserved in spirit from the Tonga reefs Examination of this material shows that large brood chambers are formed at the margin of the disc during the later stages of growth These are at first lined with a thin layer of protoplasm At a later stage the central region of the disc is found to be empty, and the whole of the protoplasm is massed in the brood chambers in the form of spores. The spores have the structure of the "primitive disc," which during the early stages of growth of the Orbitolites occupies the centre of the shells They are liberated by absorption of the walls of the brood chambers, and each becomes the centre of a new disc, which is built up by additions of successive rings of chamberlets at the margin The reproduction of Orbitolites therefore takes place by spore formation The spore contains a single nucleus, lying in its "primordial chamber" After several rings of chamberlets have been added, a stage is reached at which the nucleus appears to be represented by numbers of irregular, darkly staining masses scattered through the protoplasm of the central part of the disc In the later stages numbers of oval nuclei are found in the protoplasm, often arranged in pairs, and in favourable preparations they may be seen to be undergoing amitotic division — The fragmentation of the nosperm nucleus in certain ova, by S J Hickson. — On Gynodiœcism in the Labiatæ (second paper), by J. C. Willis. — The observations made in 1890–91 on *Origanum* (see *Reporter*, No. 937, June 7, 1892) were continued, chiefly on female plants. Six of these, derived from seed of the hermaphrodite plants of 1890, were observed, and their variations noted It seems possible that some of the six, at any rate, were derived not from the normal, but from the abnormal (female) flowers of the parent Attempts were made to determine if the occurrence of female flowers or flowers with one, two or three stamens only, on hermaphrodite plants, was due to lack of nourishment. A string was tied tightly round the main stalk of an inflorescence, about the middle, and it was found that more variations (12 : 1) occurred above than below Analysis of the three years' observations shows that the abortion of the stamens tends to occur symmetrically rather than not, *i e* most commonly all four abort, and next in frequency is the abortion of the two anteriors then of the two posteriors These observations are still in progress, and it is hoped to publish full details in 1896 or later

PARIS

Academy of Sciences, November 21 — M d'Abbadie in the chair — Observations of the minor planets, made with the great meridian instrument of the Paris Observatory, from October 1, 1891, to June 30, 1892, by M Tisserand — Determination of the centre of the mean distances of the centres of curvature of the successive developments of any plane line, by M Haton de la Goupillière — Observations of Holmes' comet (November 6, 1892) made at the great equatorial of the Bordeaux Observatory, by M G Rayet — Exploration of the higher regions of the atmosphere by means of free balloons provided with automatic recorders, by M Gustave Hermite Small balloons were filled with coal gas and provided with recording barometers and minimum thermometers The former consisted of metallic aneroid boxes on Vidi's system, recording the pressure by the motion of a smoked plate in front of a glass style. These aneroids weighed less than 100 grs. The writer hopes to reduce their weight to 10 grs Some of the balloons were lost or destroyed, but most of them were returned, after a journey exceeding in many cases 100 km Two successful registrations of temperature have been made so far, giving a fall of 1° C for every 260 m and 280 m respectively — Observations of Holmes' comet made at the Algiers Observatory (*equatorial coudé*), by MM Trépied, Rambaud, and Sy — Observations of Holmes' comet (November 6) made with the *equatorial coudé* of the Lyon Observatory, by M G Le Cadet — Elliptic elements of Holmes' comet of November 6, 1892, by M. Schulhof (see our Astronomical Column) — On the calculation of inequalities of a high order Application to the long-period lunar inequality caused by Venus, by M Maurice Hamy — Distribution into four groups of the first *n* numbers, by M Désiré André — On electric oscillations, by M Pierre Janet A gap in a circuit containing a high resistance of some 20,000 ohms is bridged by another containing a coil resistance with self induction and a bridge resistance without. The terminals in the same gap are also connected with a condenser, and a Mouton's *disjoncteur* is introduced in the circuit, rotating at a high speed The differences of potential between the terminals of the two resistances are measured by an auxiliary condenser and a ballistic galvanometer It is thus possible to determine the form of the oscillations On suddenly breaking the short circuit in the gap, it was found that the ends of the resistance without self induction reached a constant difference of potential in a series of oscillations which were always of the same sign, whereas those of the other showed a series of positive and negative oscillations. — On some results furnished by the formation of soap bubbles by means of a resinous soap, by M Izarn Very thin and permanent bubbles are obtained by pounding together 10 gr. each of colophonium and potassium carbonate, adding 100 gr of water and completely dissolving by boiling. For use, it must be diluted with four times its bulk of water — Action of piperidine upon the haloid salts of mercury, by M Raoul Varet. — On the exchanges of carbonic acid and oxygen between plants and the atmosphere, by M. Th Schlœsing, jun — A new case of living *Xiphopage*, the Orissa twins, by M. Marcel Baudouin. — Notes on the feet of batrachians and saurians, by M. A. Perrin. — On asymmetric growth in polychætous annelids, by M. de Saint Joseph. — Influence of moisture on vegetation, by M. E. Gain. Experiments with soils kept in a given state of humidity have led to the following conclusions: For each plant there exists a certain proportion of moisture most favourable to its growth A high comparative moisture in the soil accelerates the growth, especially of the stem and leaves. The air being dry, fructification is slower with a dry than with a humid soil. Inflorescence is retarded either by dry soil or by moist air, and is hastened by the reverse con-

ditions. The most favourable conditions for exuberant growth of flowers are a moist soil and dry air, especially the latter.—Researches on the mode of production of perfume in flowers, by M. E. Mesnard. By the action of pure hydrochloric acid on sections immersed in strongly-sweetened glycerine, the essential oils are easily separated. It is found that the oil is generally located in the epidermic cellules of the upper surfaces of the petals or sepals. In every case the oils appear to have been derived from chlorophyll. The perfume is not given off until the oil is sufficiently freed from the intermediate products, and it exhibits some inverse relation to the amount of tannin and pigment produced in the flower.—On the existence of a conidian apparatus in the *Uredineæ*, by M. Paul Vuillemin.—On the presence of *Actinocamax* in the Pyrenæan chalk, by MM. Roussel and de Grossouvre.—Stratigraphic consequences of the preceding communication, by M. A. de Grossouvre.—On the formation of the Arve valley, by M. Emile Haug.—On an experiment which appears to produce an artificial imitation of the doubling of the canals of Mars, by M. Stanislas Meunier.

DIARY OF SOCIETIES.

LONDON

THURSDAY, DECEMBER 1.

LINNEAN SOCIETY, at 8.—Notes on Œcodoma cephalotes and the Fungi it Cultivates: J. H. Hart.—On a Small Collection of Crinoids from the Sahul Bank, North Australia: Prof. F. Jeffrey Bell.—Descriptions of Twenty-six New Species of Land Shells from Borneo: E. A. Smith.

CHEMICAL SOCIETY, at 8.—On the Formation of Orcinol and other Condensation Products from Dehydracetic Acid: J. Norman Collie.—Isolation of Two Predicted Hydrates of Nitric Acid: S. U. Pickering.—Anhydrous Oxalic Acid: W. W. Fisher.—Observations on the Origin of Colour and of Fluorescence: W. N. Hartley.—The Origin of Colour—Azobenzene: H. E. Armstrong.—The Reduction Products of *αα'* dimethyl *αα'* diacetylpentane: Dr. Kipping.—The Products of the Action of Sulphuric Acid on Camphor: Drs. Armstrong and Kipping.—Methods for Showing the Spectra of easily Volatile Metals and their Salts, and of Separating their Spectra from those of the Alkaline Earths: W. N. Hartley.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Experimental Researches on Alternate Current Transformers: Prof. J. A. Fleming, F.R.S. (Discussion.)

LONDON INSTITUTION, at 6.—Photographs of Flying Bullets, &c. (Illustrated): Prof. C. V. Boys, F.R.S.

SUNDAY, DECEMBER 4.

SUNDAY LECTURE SOCIETY, at 4.—Bacteria and Infectious Diseases (with Oxy-hydrogen Lantern Illustrations): Dr. E. E. Klein, F.R.S.

MONDAY, DECEMBER 5.

SOCIETY OF ARTS, at 8.—The Generation of Light from Coal Gas: Prof. Vivian B. Lewes.

VICTORIA INSTITUTE, at 8.—Principles of Rank among Animals: Prof. Parker.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—A New Form of Filter Press for Laboratory Use: C. C. Hutchinson.—The Production of Acetic Acid from the Carbohydrates: Messrs. Cross and Bevan.—Electrolytic Soda and Chlorine; the Present Aspects of the Question: Messrs. Cross and Bevan.

LONDON INSTITUTION, at 5.—Reading as a Recreation: Edmund Gosse.

ROYAL INSTITUTION, at 5.—General Monthly Meeting.

ARISTOTELIAN SOCIETY, at 8.—Symposium—Does Law in Nature exclude the Possibility of Miracle? R. J. Ryle, Rev. C. J. Shebbeare, A. F. Shand.

TUESDAY, DECEMBER 6.

ZOOLOGICAL SOCIETY, at 8.30.—A Revision of the Genera of the Alcyonaria Stolonifera, with Descriptions of One New Genus and several New Species: Sydney J. Hickson.—Upon the Convolutions of the Cerebral Hemispheres in Certain Rodents: F. E. Beddard, F.R.S.—On a New Monkey from South East Sumatra: Prof. Collett.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Monthly Ballot for Members.—The Manufacture of Small Arms: John Rigby. (Discussion.)

WEDNESDAY, DECEMBER 7.

GEOLOGICAL SOCIETY, at 8.—Note on the Nufenen-stock (Lepontine Alps): Prof. T. G. Bonney, F.R.S.—On some Schistose "Greenstones" and Allied Hornblendic Schists from the Pennine Alps, as Illustrative of the Effects of Pressure-Metamorphism: Prof. T. G. Bonney, F.R.S.—On a Secondary Development of Biotite and of Hornblende in Crystalline Schists from the Binnenthal: Prof. T. G. Bonney, F.R.S.—Geological Notes on the Bridgewater District in Eastern Ontario: J. H. Collins.

SOCIETY OF ARTS, at 8.—The Chicago Exhibition, 1893: James Dredge.

ENTOMOLOGICAL SOCIETY, at 7.—Further Observations upon Lepidoptera (Illustrated by the Oxy-hydrogen Lantern): Edward B. Poulton, F.R.S.—The Effects of Temperature on the Colouring of Pieris napi, Vanessa atalanta, Chrysophanus phlœas, and Tephrosia punctulata: Frederic Merrifield.—Notes on Hydroptilidæ belonging to the European Fauna, with Descriptions of New Species: Kenneth J. Morton. (Communicated by Robert McLachlan, F.R.S.)—On some Neglected Points in the Structure of the Pupa of Heterocerous Lepidoptera, and their Probable Value in Classification; with some Associated Observations on Larval Prolegs: Dr. Thomas Algernon Chapman.—Description of a New Species of Butterfly, of the Genus Cyllinaga, from Siam: James Cosmo Melvill.

THURSDAY, DECEMBER 8.

ROYAL SOCIETY, at 4.30.—On the Photographic Spectra of some of the Brighter Stars: Prof. J. Norman Lockyer, F.R.S.—Experiments in Examination of the Peripheral Distribution of the Fibres of the Posterior Roots of some Spinal Nerves: Dr. Sherrington.—Preliminary Account of the Nephridia and Body Cavity of the Larva of Palæmonetes varians: Edgar J. Allen.

MATHEMATICAL SOCIETY, at 8.—Note on Cauchy's Condensation Test for the Convergency of Series: Prof. M. J. M. Hill.—Additional Note on Secondary Tucker Circles: J. Griffiths.—Notes on Determinants: J. E. Campbell.—A Geometrical Note: R. Tucker.

LONDON INSTITUTION, at 7.—A Plea for Catholicity of Taste in Music (Illustrated): Sir Joseph Barnby.

SATURDAY, DECEMBER 10.

INSTITUTION OF CIVIL ENGINEERS, 1 to 4.—Students' Visit to the Machinery and Inventions Division, South Kensington Museum.

BOOKS, PAMPHLETS, and SERIALS RECEIVED

BOOKS.—Berzelius und Liebig, Briefwechsel 1831–1845 (München, Lehmann).—A Short Manual of Orthopædy, Part I.: H. Bigg (Churchill).—Congrès International de Zoologie, Deux Session à Moscou. Première Partie (Moscou).—Congrès International d'Archéologie 11-ème Session à Moscou, vol. 1 (Moscou).—A Catalogue of British Jurassic Gasteropoda: W. H. Hudleston and E. Wilson (Dulau).—Annuaire de l'Observatoire Municipal de Montsouris, 1892–93 (Paris, Gauthier Villars).—Les Textiles Végétaux: H. Lecomte (Paris, Gauthier-Villars).—Essais d'Or et d'Argent: H. Gautier (Paris, Gauthier Villars).—Past and Future: C. M. Jessop (K. Paul).—Toothed Gearing: A Foreman Pattern Maker (C. Lockwood).—Modern Views of Electricity, 2nd edition: Prof. O. J. Lodge (Macmillan).—The Universal Atlas, Part 21 (Cassell).—Grasses of the Pacific Slope, Part 1: Dr. G. Vasey (Washington).—Das Keimplasma, Eine Theorie des Vererbung: Prof. A. Weismann (Jena, Fischer).—Die Zelle und die Gewebe: Prof. O. Hertwig (Jena, Fischer).—Extinct Monsters: Rev. H. N. Hutchinson (Chapman and Hall).—The Algebra of Coplanar Vectors and Trigonometry: R. B. Hayward (Macmillan).—Science in Arcady: Grant Allen (Lawrence and Bullen).—The Chemical Basis of the Animal Body: Dr. A. Sheridan Lea (Macmillan).

PAMPHLETS.—Quelle est la Race la plus Ancienne de la Russie Centrale: A. Bogdanow (Moscou).—Descriptive Notes on certain Implements, Weapons, &c., from Graham Island, Queen Charlotte Islands, &c.: A. Mackenzie.—Notes on the Shuswap People of British Columbia: G. M. Dawson.—Some Laws of Heredity and their Application to Man: S. S. THE NEW UNIVERSITY QUESTION

THE correspondence between Prof Huxley and Prof Pearson which has appeared in the *Times* is not pleasant reading With infinite pains and trouble an Association had been formed to support the foundation in London of a university of a certain type A nucleus of the most eminent teachers or ex-teachers in London had collected around them a powerful body of supporters from the provinces In Prof Huxley as President, and Sir Henry Roscoe as Vice-President, the Association secured the services of two men distinguished both as professors and for their knowledge of affairs It appears to have been less fortunate in its secretary Prof Karl Pearson had some difference with his fellow committee-men on a question of procedure He himself has described the divergence as not fundamental and has publicly stated that he believes that the other members of the committee were aiming at securing the establishment of a university of the type which he himself approves So comparatively trifling was the issue, that, according to Prof Huxley, Prof Pearson himself proposed that the reason to be given for his resignation should be "pressure of work" No doubt can therefore exist as to the cogency of this motive His position was apparently even more clearly defined by his not voting against the course of action proposed on the occasion of a meeting which was shortly to take place between the Senate of the University of London and the Committee of the Association, and by his spontaneously pledging himself "to say nothing as a member of the deputation, contrary to what was then agreed to"

It is therefore no wonder that Prof Huxley was surprised, when on the very next day Prof Pearson wrote to the *Times*, discussing resolutions which Prof Huxley regarded as confidential and accusing his colleagues of various offences, of which the day before he thought so little that he had voluntarily stated that "pressure of work" was the reason to be given for his resignation

One good result may perhaps follow from Prof Pearson's action Owing to the sense which has unfortunately been attached to the word "absorb," and to the assumption that the title "Professorial University" meant a University governed solely by Professors, an opinion has got about that the members of the Association are impracticable persons, who have propounded an unworkable scheme It is true that both accusations are directly met by the published programme of the Association It is there made clear that a voluntary absorption is all that is aimed at, and that laymen as well as experts are to have a share in the management of the University Prof Pearson's defection has made it still more obvious that the Association scheme is intended, not to gratify theorists, but to support a policy which is capable of realization

Prof Pearson declares that he desires a University on the model of Berlin, but the question at once arises, Is the model to be followed exactly, or are modifications to be introduced? Is the University to be free from all State control? Prof Huxley desires that it shall be free, and under existing circumstances we cordially agree with him Let the State, if it will, nay as it must, support and subsidize the new University as it supports the British Museum, but let the control of the one, as of the other, be in the hands of an independent Governing Body But, if this condition is realized, there is at once a fundamental difference between the actual University of Berlin and the possible University of London The external element furnished in Germany by State control must in England be supplied by lay members of the Governing Body, and the difference thus established will run throughout the whole of the constitution

Prof. Huxley publishes in his letter to the *Times* an outline of a scheme for the organization of the University which is too interesting to be omitted here He explains that he gives the rough notes on which his evidence before the Gresham University Commission was based

The scheme is as follows —

"Do not venture to ask for all I want, but for as much as it seems possible to get on the way to that

"Suggestions tentative and open to modification

"(*a*) Retain title and prestige of University of London, reorganize it in such a manner as to secure general uniformity and efficiency of work with freedom and elasticity In short, unify without fettering

"(*b*) Make the institutions which contain technical schools of theology, law, medicine, engineering, and so on into colleges of the University Let these examine their own candidates for degrees, under conditions determined jointly by them and the Senate of the University, and present such as they declare fit to the University for *ad eundem* graduation

"(*c*) Deal in the same way with institutions giving adequate instruction in the other categories of University work—if they so please, or let the University examine

"(*d*) Provide ample means for instruction in the modes of advancing natural knowledge and art, either in material connexion with the existing University or in particular colleges

"(*e*) Professoriate to have large but not preponderant representation in Senate, and wide, but not exclusive, influence in regulating instruction and examination in accordance with the general aim at unification.

"(*f*) All state and municipal contributions, private endowments and University fees for instruction and examination to be paid into a University chest All professorial staff and current expenses (save in cases that may be reserved) to be paid out of the University chest, also building and fitting expenses where there is no sufficient endowment of a college The payment of the professorial staff to be primarily regulated by the kind and amount of the work done for the University, not by number of students.

"(*g*) No bar to be placed in the way of any one who desires to profit by any description of University instruction If, after trial, he does not profit, time enough to exclude. Value of exclusion as disciplinary measure."

Any one who takes the trouble to compare this scheme with the original programme of the Association will see that they are in close accord It is true that the Association put forward the complete voluntary absorption of the colleges as the result most to be desired, but it distinctly contemplated the possibility of relations between the University and institutions or colleges which were not completely absorbed, and it will be seen that the only terms on which Prof Huxley will permit relations to be established between the University and the colleges secure to the former a very large measure of authority

Prof Huxley himself describes his scheme as of a tentative character, but whatever plan be finally adopted it is desirable that the real aims and objects of the Association shall be fully understood

It is desired that there shall be one University in London which shall be a central authority to organize and improve higher education

No reasonable person has ever supposed that the existing University of London was to be destroyed as a sort of peace-offering to its critics, or that existing colleges were to be ignored or dragooned into self-effacement What is desired is that the Senate of the existing University should be reconstituted by the addition of professors teaching under the control of the University and by a reduction in the number of its lay members, if, with the new additions, it would otherwise be of unwieldy size

It is desired that a share in the benefits to be obtained from the University should be given to any college only in so far as it is willing to put into the hands of the University the appointment and control of those of its chairs which might be recognized by the University It is hoped that the advantages which would accrue from this partial fusion would be so great as to lead to the gradual voluntary "absorption" of the colleges To make this desirable end attainable it is necessary that the College Councils should not be represented, as such, on the Governing Body of the University, but no objection would, we believe, be felt to temporary arrangements which might facilitate the inauguration of the new state of things

The sooner it is clearly understood that the Association is the result of the labours and the exponent of the views of the "practical men" who are, according to Prof Huxley, to be found in the professorial ranks, the better it will be for the Association and for London Prof Pearson's withdrawal from the secretaryship appears, under all the circumstances, to afford a sufficient guarantee of this

IN SAVAGE ISLES AND SETTLED LANDS

In Savage Isles and Settled Lands Malaysia, Australasia, and Polynesia, 1888–1891 By B F S Baden-Powell, Lieut. Scots Guards, F R G S (London Richard Bentley and Son, 1892)

THIS book contains the impressions of Lieut Baden-Powell during a journey round the world of over three years' duration, jottings limited chiefly to his own personal doings and observations. The journey was evidently a leisurely peregrination with many divergences to places of interest off his direct route out to Brisbane in Queensland, whither he was bound to assume official duty on the staff of the governor of that colony, and an equally unhurried saunter home again through the Pacific and America The author does not propose to look at things with scientific eyes, and it is possible here and there throughout the book to detect that he has no profound acquaintance with the *ologies* Consequently his book does not fall to be rigidly criticized in these pages. His eyes, however, if not scientific, were kept at all events very wide open, and what came under his own observation is clearly and accurately described in a chatty and pleasant style and with a good deal of quiet humour It is easy to see that the "tramp" enjoyed his trip, and the reader, drawn on by his cicerone's mood, accompanies him through savage isles and settled lands with equal satisfaction Lieut Baden-Powell started off through the European continent *viâ* Cologne and Vienna to Rustchuk, thence across Bulgaria, through which "a railway journey is not very interesting" Nevertheless, "little picturesque villages are seen nestling in the valleys, and distant glimpses of the Balkans gained" Beyond Shumla we get through the mountains and "pass through miles of swamp, the railway almost level with the water, and reeds growing up all around, in some places so high as to cut out all view from the carriage windows Passing along the edges of large lakes, the train starts up thousands of wild fowl, which fly around till the air is quite darkened by them, and on we go, mile after mile, with more and more duck rising from the water," evidently a sportsman's paradise Thence our guide conducts us to Constantinople and on to Egypt, and though he takes us by well-trodden paths and tells us little that is new or wonderful, he enlivens the way with a constant flow of time beguiling talk and anecdote From Egypt Mr Baden-Powell sets out for southern Australia, but he wanders as usual off his main road for some weeks into Ceylon and India to luxuriate amid their tropic scenery and ancient monuments Of the three southern colonies of the Australias traversed on his way to Queensland he gives us a few brief notes Of the latter colony, where he spent some years in the enjoyable and not very arduous duties of A D C to Sir Anthony Musgrave and Sir Henry Norman, he has a great deal that is interesting to tell He visited much of the country, and saw something of its aboriginal as well as of its adopted natives, and found interest and amusement in both. At a vice-regal ball at Hughenden, a town 240 miles inland, he finds himself a fellow-guest with the butler of the hotel he was staying at, and his host's housemaid, "who was quite the belle of the ball, and who, when supper was served, turned waitress again Such is society in a Bush town" "It was in this district," he continues, "that I first set eyes on some real wild blacks. The aboriginals of Australia are an extraordinary people. To look at they are quite unlike any other human beings I ever saw A thick tangled mass of black hair crowns their heads, their features are of the coarsest, very large broad and flattened noses, small, sharp, bead-like eyes and heavy eyebrows They generally have a coarse tangled bit of beard, skin very dark and limbs extraordinarily attenuated like mere bones But they always carry themselves very erect . . They wander about stark naked over the less settled districts, and live entirely on what they can pick up . If not the lowest type of humanity they would be hard to beat. They show but few signs of human instinct, and in their ways seem to be really more like beasts." Mr. Baden-Powell thus summarizes his opinions on Australia as a field for emigration (and those who know the Australasian colonies will recognize their truth): "The labouring man will find it a paradise; the professional man will find his profession overstocked, and the man with money to invest will probably be ruined. . . . My personal advice to would-

be emigrants except of the lowest [? lower] class is like *Punch's*—Don't"

From Queensland it was easy and natural for our traveller to be attracted across to New Guinea, the land of so much myth and mystery Here he fell in with the indefatigable administrator, Sir W Macgregor, and was able to lend him a helping hand in the skirmishing incident on the capture of the natives of some villages guilty of the murder of several Europeans He spent some days at Samarai, the head-quarters of the south-eastern district, and we feel sure that the almost unsurpassable panorama visible from its hill-set bungalow of "mountains wooded to the peak," and green isles, spread out on every side, basking in an azure sea, and picturesquely veiled in haze as they lessen away to beyond the horizon, must have rewarded him for his visit, even at the expense of a bout of fever His account of what he saw and did in Papua occupies some eighty pages, and contains more trustworthy and interesting information than many of the narratives of men who have spent a much longer time in the country than Mr Baden-Powell did The next region he visited was the Malay Archipelago He only gazed on Sumatra, "that extraordinary island which contains probably a greater variety of big game, of useful plants, and of wonderful scenery than any other country of its size", but he visited many of the most interesting places in Java, and the Straits Settlements, and made extensive journeys in Borneo, where he shot some of "the very extraordinary-looking proboscis-monkeys (*Larvatus nasalis*) I should imagine," he remarks, "his ponderous nose would get very much in the way of his biting any one, and he certainly has no other means of defence" Our space will not permit us to follow Mr Baden-Powell through New Zealand and the various islands of the Pacific sojourned in by him, except to note his account of the preparation of "king's cava," of which he was a witness, in Samoa —

"This was a great event None of the Consuls even had ever before partaken of 'king's cava' But there was a certain amount of sham about it. First, the root was produced—genuine enough, I dare say Six men then sat in a row outside the house, the nine-legged cava bowl before them Each man was then given some water to wash his mouth out, and a packet of cava wrapped in a bit of leaf was given to each I shuddered at the awful thought of what was about to happen In true native fashion these nasty old men were undoubtedly going to chew the root, and I would have to swallow the nauseous stuff! I watched very carefully and was much relieved when I saw the packets collected again and put in the bowl. It was ready prepared [outside in a less orthodox and less disquieting fashion] and the little ceremony was only to represent formally the mode in which it ought to be done, the cava being 'taken as chewed.' Then the bowl was solemnly brought into the house and put on the floor at the end opposite the king"

This is an interesting instance of the evolution of what might have been as meaningless a ceremonial as are many of those survivals of abandoned customs which are familiar to us in many other parts of the world.

From Samoa Lieut. Baden-Powell made his way home by the usual route *viâ* the Sandwich Islands and through the States.

"In Savage Isles and Settled Lands" is a book we can heartily recommend. It is elegantly got up, is illustrated by excellent wood engravings, and has a map of the author's route. Nearly every page presents in a few words some bright vignette that will please and inform those who have never had the opportunity of visiting those lands and isles, and will set the home-come traveller a-dreaming with grateful satisfaction of delightful days that are past, and help him to live them over again more delightfully still in the present.

H O F

PROPERTY

Property Its Origin and Development By Chas Letourneau, General Secretary to the Anthropological Society of Paris, and Professor in the School of Anthropology (Walter Scott, 1892)

LESS than a generation ago the history of early civilization was summed up, if not in the three words hunting, pasture, and agriculture, at least in the formula of Sir Henry Maine "Society develops from family to tribe, and from tribe to State" Recent inquiries have discredited both of these formulas, and taken us back to the genesis of the family itself, and beyond civilization to barbarism and savagery If we listen to Prof. Letourneau (to say nothing of Morgan and Maclennan), we may reconstruct the evolution of society in all its stages out of savagery by the "ethnographic method,"—"looking upon existing inferior races as living representatives of our primitive ancestors" (Preface, page ix) It must be remembered that in using this ethnographic method we assume that the order of progress has been substantially identical in all cases, and also that the simplest forms come first in time (p 70, cf. 126) Both assumptions would need justification before the results of the new method could be finally accepted.

Prof. Letourneau had applied the method with great learning and ingenuity in his earlier book on the evolution of marriage In the volume before us he applies it to property He begins with a chapter on property amongst animals, ants and bees, as we might expect, are shown to be more highly developed in this matter than many men, and they have many of the vices of men They provide for the future Their property is that of a community, but one community wars on another for pillage. There are not only parasites, but idle aristocrats among them. The amazon ants, who cannot even feed themselves, but depend on their black slaves, are well known from Huber's description, and are a standing refutation of Solomon's high opinion of ants. On the whole, among animals, property is due simply to the instinct of self-preservation, and Letourneau ascribes it to the same origin in the case of men Among the "anarchic hordes," which come first in his series (p. 23), and of which the Fuegians are a specimen, there is collective property If union is strength it is weakness that first leads to union (cf p 368) But there is no personal property except in tools and weapons, "the immediate result of personal labour" (p 39) Provision for the future is unknown In the second stage (among the "republican tribes") the union is more highly organized; there is tribal government, with minute regulation of conduct in regard to the dealings of individuals with the necessaries of life. The most remarkable example is perhaps that of the people of Paraguay

among whom (as our author shows) the Jesuit missionaries found and did not make a system of communism (pp. 42 seq) In nearly all the instances of this class the sense of property was most strongly developed in regard to the hunting ground of the tribe, though (in the case of the Iroquois, &c) it embraced the Long Houses of the clans of the tribe, an anticipation of Fourier's phalansteries The differentiation of the clan from the tribe is ascribed to the growth of the taste for property itself (cf. p 365) Letourneau would explain the present universality of human sympathy as a bequest to us from the days when all property was common (p. 57) The republican organization passed into the monarchical, where the tribe was governed by its chief (pp 56 seq) This political change was rather an effect than a cause of coincident industrial changes, especially the introduction of private property in slaves and women "A comparison of the American tribes, placing them in a graduated series from the primitive system of communistic equality upward, plainly shows that, at least in this part of the world the establishment of aristocracy and hereditary monarchic power has merely crowned an economic evolution whereof the point of departure was the institution of slavery, and the consequent development of agriculture, whence arose the rupture of primitive equality, creation of exchangeable values, development of private property, contrast between rich and poor, foundation of castes, and hereditary succession" (p 61) This passage, amongst others, betrays the tendency—fashionable in some quarters at the present time—to regard all social development as due mainly, if not wholly, to economic causes Not that economists by profession are *gratæ personæ* to our author On the contrary, they are only mentioned to be rebuked, and their doctrines only to be caricatured (see pp 91, 96, cf 120, 124, &c) But, as by some sections of German Socialists, so by Letourneau, we are given to understand that the politics, religion, and general character of a society are determined by the conditions of industry and the terms of property therein prevailing, while no sufficient allowance is made for the reaction of the former set of phenomena on the latter

To sum up at this third stage in the development from savagery (the early monarchical system), the idea of personal property is extended from weapons and tools which a man has made, to the trees which he has planted, and then to the plot of ground he has cleared and sown After that the idea of private property may be considered to be full formed and definitely launched on its modern career of development (p. 72) The great cause of private property is agriculture Where there was only pasture, as with the Hottentots, the private property was only in cattle, women, and children (p 79) Agriculture brings us to extended forms of slavery, and to forms of property and modes of valuing and exchanging it that approach more and more to modern ideas

We need not follow our author into the *minutiæ* of his account of "primitive monarchies" and empires. He gives a survey of mankind from China to Peru, and from the earliest times to the period of Roman, feudal, and modern civilization. The earliest stages of the development are (rightly enough) treated more fully than the later, the later being the more generally known The differentiation of clan from tribe and of family from clan, the formation of village communities for the purpose of agriculture, the introduction of inheritance, and of private property in estates, are all traced out in chapters that are full of interest even when not above cavil

Prof Letourneau has perhaps been too ready to point a moral for the benefit of his own generation But after all he gives his readers the facts, and they may find their own moral, which may or may not be his One of the best instances where the materials presented seem to justify a different moral than the one drawn from them is that of the *dessa* or village community of Java It is pronounced to have excellent results, particularly in increasing population (p 121), and is contrasted with "the selfish African system" (p 122), but by our author's own account it is a combination of private and collective property, not an example of the latter by itself (cf pp 114, 115).

The book is, we may presume, translated from the French, and this will account for the use of "alienist" for "lunacy doctor" (p 370), "disengaging" for "analyzing" (p 373), and "salaried" for "wages-earning" (p 375) But, as a rule, the language is correct and clear English

J B

LEAPER'S "OUTLINES OF ORGANIC CHEMISTRY"

Outlines of Organic Chemistry By Clement J Leaper, F C S Specially written for Schools and Classes connected with the Department of Science and Art (London Iliffe and Son, 1892)

THIS little work is intended, as the title states, for the use of beginners But the author has made the way of beginners hard, by leaving in his pages the largest collection of misprints and other slips which we recollect to have met with in so small a compass.

On the very first page, in the opening lines, there occurs a wrong formula for urea, and the book ends with a wrong formula for aldehyde-ammonia We do not propose to convert this notice into a table of errata, but the following may be given as illustrating the sort of guidance which the beginner may expect On p 75, in the brief space of three lines, we meet with "$(COOH_2)$," "$C_3H_5(OH_3)$" and "$C_3H_5(OH_2)COOH$," as representing respectively oxalic acid, glycerin, and—monoformin! The blunder, in each case, consists, of course, in placing a coefficient inside instead of outside the bracket, but we doubt whether, even with this correction, the last expression, with its carboxyl-group in place of the group O CHO, would be recognized, even by an experienced chemist, much less by a beginner, as representing monoformin

Blunders, due to carelessness, are not confined to formulæ Thus we find "Pure white precipitate of silver *oxide* (p 13), whereas the context shows that silver *chloride* is meant, "*ethene* dichloride, $C_2H_2Cl_2$" (p 37), "lead the gas into lime water, and note the formation of insoluble *carbon dioxide* (p 51); "by the further chlorination of methyl chloride we get *ethylidene* chloride" (p 67), whilst, on p 99, "grains" is twice given instead of "grams" But the worst blunder we have met with occurs on p. 109, where, possibly owing to a transposition of the pages of the author's manuscript, the explanations

which should follow Experiment 112 (Preparation of Ethyl Nitrite) have been moved on by a whole page, and made to follow Experiment 115 (Preparation of Nitro-ethane) The utterly bewildering effect of this jumble, which is enhanced by the unexpected re-entrance of the subject of nitro-ethane in the middle of a paragraph a little later on, cannot be realized without reading the passage

The work is intended to combine practical with theoretical instruction The selection of experiments is, on the whole, judicious, and the practical directions are generally good This is not to be wondered at, as the author has evidently, in these points, followed pretty closely Prof Emerson Reynolds's "Experimental Chemistry," even to such details as the substitution of a tin oil-can for a distilling flask (p 99), or a peculiarity in the bending of a tube (p 74), and to the reproduction of some of the illustrations—in every case without acknowledgment Prof Reynolds is not, however, responsible for the illustration on p 17, in which the distillate from a Liebig's condenser is represented as falling from a considerable height into a flask placed below

It is not true that (p 12) "every organic compound containing nitrogen will, when fused with metallic sodium, convert the latter into sodium cyanide" Diazo-compounds do not yield any cyanide, and compounds containing sulphur as well as nitrogen form thiocyanate Nor is heating a cyanide with excess of concentrated sulphuric acid (p 76) a method of distinguishing it from a formate

The author's style is occasionally slovenly, and sometimes worse "Observe how the fact that oxalic acid so readily split up into CO, CO_2 and H_2O support (*sic*) this graphic formula for it" (p 117)

On the whole, we suspect that teachers will prefer a text-book which calls for fewer marginal corrections

OUR BOOK SHELF

An Introduction to the Study of Botany, with a special chapter on some Australian Natural Orders By Arthur Dendy, D Sc, and A H S Lucas, M A Small 8vo, 272 pages with about 30 pages of woodcuts (Melbourne and London Melville, Mullen and Slade, 1892)

THE authors of this little work are both teachers of Natural Science in the University of Melbourne and it is specially intended for the use of students in Australia With this object in view it would have been better perhaps to have selected common Australian types to illustrate the life history of the great divisions of the vegetable kingdom; but *Pinus* is taken as a representative of gymnosperms and *Vicia* of angiosperms Whether these plants are both easily procurable in Australia we are unable to say, but even in that case it would have been better to have taken native plants Possibly the preparation of illustrations may have influenced the authors, for they are largely, in the first part, "modified," "simplified," or "adapted" figures from well known books, or they are simply copied Taken as a whole, we do not doubt that this primer will prove useful to students, but it needs much revision to make it what it ought to be Here and there, where we have tested it, we have found serious shortcomings. Take for example the account of the divisions of the vascular cryptogams

"1. *Filicineæ*.—These are the ferns which constitute a very large and interesting subdivision The full account already given of the common bracken renders a detailed description unnecessary in this place There are two principal subdivisions of the *Filicineæ*, the homosporous, which produce only one kind of spore, and the heterosporous, which produce large megaspores and small microspores The former include all the ordinary ferns and are again subdivided into six 'families,' of which the Polypodiaceæ are the best known and most abundant, including most of the common ferns, such as Pteris"

One would have expected a word or two respecting the heterosporous group—the *Rhizocarpeæ*, with some mention of *Marsilea*, so memorable in the history of Australian exploration, but the authors seem to have come to grief between the older and newer classifications of vascular cryptogams, for in another place (p 90) we read of "heterosporous ferns" The definition of the *Equisetineæ* contains no reference to the spores, and the description of the *Lycopodineæ* contains no information at all It runs thus "This group includes the club-mosses (*Lycopodium*) and the beautiful *Selaginella*, a plant frequently grown in conservatories for decorative purposes They are all of rather small size, and are popularly spoken of as "mosses" owing to the general appearance of the plant with its numerous very small leaves"

Comment on such a description would be superfluous In the classification of the cellular cryptogams, lichens are altogether left out, and are apparently not mentioned anywhere In fact the same incompleteness and inexactness pervades the book, which opens with a eulogistic preface by W Baldwin Spencer, Professor of Biology in the University of Melbourne W B H

A German Science Reader (Modern German Series) Compiled by Francis Jones, F R S E (London Percival and Co, 1892)

THE idea of introducing to English readers extracts from the works of many well known German scientific authorities will be thoroughly welcomed The author has brought together sixteen very interesting articles on several branches of science, supplemented with notes, in which difficult passages are translated, and a glossary of the technical terms not usually found in dictionaries Among the articles we may mention, Electric Telegraphs by Bernstein, Ice and Snow by Kantz, Air by Muller, Aniline Dyes by Kekulé, Spectrum Analysis by Kirchhoff and Bunsen, &c W

More About Wild Nature By Mrs Brightwen (London T Fisher Unwin, 1892)

MRS BRIGHTWEN'S book on "Wild Nature Won by Kindness" was so widely appreciated that she has been encouraged to prepare a second volume of the same general character It speaks well for her knowledge of animals, and for her interest in their habits, that the new sketches are written in as fresh and bright a style as if she had never before occupied herself with the mass of subjects with which she deals. She is a careful and accurate observer, and all readers who care for natural history will find much to please them in the facts and impressions she records The author's illustrations add greatly to the charm of the text.

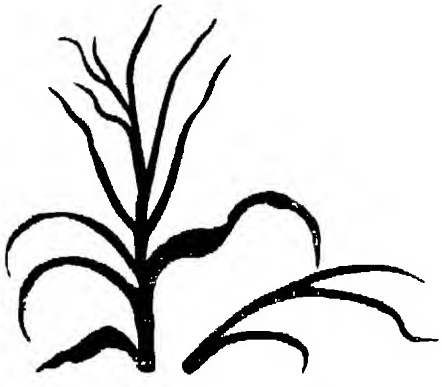
LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Arborescent Frost Patterns

ON Sunday last, December 4, I observed a curious phenomenon, which I do not remember having ever seen before in the streets of London Along the Euston Road, the Marylebone

Road, and other thoroughfares having an east and west direction the paving flags were all covered with a striking, vegetable-like pattern which might be most appropriately described as an arborescent tracery The pattern was not formed of the usual small and delicate frost figures such as we are familiar with on window panes, but was made up of large and boldly fronded designs such as shown in the sketch, which I hurriedly made on the spot —



The "fronds" were from one to two feet in length, and often most gracefully curved A keen wind was blowing at the time from a few degrees north of west and the flags had evidently been coated with a thin layer of mud from the previous night's rain I attribute the pattern to the rapid freezing and evaporation of the water in this surface layer of mud which was going on during the morning I only noticed the tracery along east and west thoroughfares, in sheltered streets not swept by the cold wind no design was visible The phenomenon may be known well enough to others, but by many, like myself, it may have hitherto been passed over unnoticed My chief object in sending this description is to call attention to the very vegetable-like appearance of the pattern If allowed to dry in a calm atmosphere and then buried under a fine alluvial or other deposit a record would be preserved which the future geologist might at first sight be tempted to read as "vegetable remains" I have seen very similar tracery in the London clay about Clacton on Sea and elsewhere. R MELDOLA

Ice Crystallites

THE interesting facts recorded by your correspondent C M Irvine on p 31 recall some unrecorded observations of my own On several occasions during recent winters I have observed these crystallographic forms of ice on a gravel walk by the side of my lawn, in places where, owing to faulty gradients, the water does not completely drain away at the surface, and the ground just below the surface is in consequence more saturated with water than at other spots. The acicular ice forms have appeared in bundles standing up between the pebbles and capped by earthy material, just as described by Mr Irvine, and in previous communications to NATURE by Mr H Woodd Smith (see his letter on p 79) The nature of the soil agrees with that described by these two observers, so far as permeability to water is concerned, and I think they appeared on the occurrence of clear frosty weather after a thaw and melting of previous snow My observations, however, extended further than theirs appear to have done I was at the time pursuing the study of the glassy acicular *crystallites* of sulphur (which are erroneously described as "crystals" in most text-books on chemistry) These, on examination with polarized light (as I have described elsewhere) are found to be destitute of any crystalline internal structure (in fact truly vitreous or isotropic masses in spite of their crystallographic outlines), such structure developing, as devitrification proceeds, by crystallization in the orthorhombic system, to which the outlines of the crystallites do not conform

In NATURE (vol. xxxvii. p 104) is a letter from myself, recording some observations on the vitreosity of ice, as exhibited under certain suitable conditions by hailstones, and referring to a previous letter (*Ibid* vol. xxxvi. p 77), wherein the vitrification and devitrification of water was suggested as the possible cause of certain structural phenomena observed in them from time to time It was with those ideas present to my mind that during recent winters I have made an examination of the acicular ice forms referred to, which struck me as made up of unusually clear and transparent ice On taking my microscope out of doors, fitted with a polarizing apparatus, when the temperature was a few degrees below freezing, with a thick overcoat on to prevent the heat of one's body from affecting the ice-needles, I found that, on taking them from the ground and placing them at once on the stage between crossed "Nicols," they appeared to be *completely isotropic*, as they had no reaction on polarized light I have concluded, therefore, that these ice needles are strictly analogous (physically) to the prismatic crystallites of sulphur, and they resemble precisely the microscopic lathe shaped forms, into which I have seen a perfectly clear minute plate of sulphur-glass break up in the first stage of devitrification The explanation suggested by Mr Woodd Smith, that they may have been formed by a slow growth of ice at their base, the molecular movement of water in the soil keeping up the supply so long as refrigeration continued, has seemed to me the most natural one, their isotropic molecular structure is no doubt due to the rapidity of freezing owing to a sudden fall of temperature at the spot A IRVINE

Wellington College, Berks, November 27

The *Volucellæ* as Alleged Examples of Variation "almost Unique among Animals"

IT is barren work for the parties in a controversy merely to deny each other's statements without adducing further evidence Mr Bateson first stated that var *mystacea* did not mimic *Bombus muscorum* I replied that it did, and the statement in my letter in no way depended on the case at the Royal College of Surgeons, but on a careful comparison of the insects in the Oxford Museum It is useless for me to repeat that I regard it as an example of mimicry, not indeed equal to that afforded by the same fly and *Bombus hortorum*, but far better than many others which are generally believed to be instances of this principle (such as the resemblance of *Clytus arietis*, or even the resemblance—admitted by Mr Bateson in his first letter—of *Volucella inanis*, to a wasp) I therefore propose to furnish the Editor of NATURE with photographs of the *Volucellæ* and humble bees for reproduction, so that readers can judge of the matter for themselves I will do my best to obtain a negative which shows the coloured bands

Although I believed that the two London Museums supported my view, it will be obvious to any one who reads the letter that I did not rely on such support, but on my own comparison of the insects

Mr Bateson has offered no further evidence in support of his remarkable assertion that the variation of the *Volucellæ* is unique I am not surprised that he should pass over this part of my letter, for I felt sure that there was no further evidence to offer It will be remembered that this evidence was contained in the "brief statement of facts" given in his first letter, and is practically summed up in the sentence "This fly exhibits the rare condition of existing in two distinct forms in both sexes" In assuming this rarity to be so excessive that the words "almost unique" may be applied to it, and in evidently considering that we must proceed as far as the peach and nectarine in order to find a parallel, Mr Bateson exhibits a want of acquaintance with the facts of variation which is very surprising in one who is believed to have spent some years in their study For there is no essential biological difference between this variation and many others, examples of which I gave in my last letter, and which could easily be multiplied In fact, many a "showcase" would have corrected such a mistake Compared with the magnitude of this erroneous statement in Mr Bateson's first letter, the details under discussion assume very small proportions In considering that "no speculation is needed to enhance the exceptionally interesting facts of the variation and the resemblances of the *Volucellæ*," it would appear that Mr Bateson seeks to replace that most invaluable servant of science, speculation, by far reaching and unsupported assertion.

In his last letter Mr Bateson says "it is admitted that in making this statement Mr Poulton relied not on original authorities, but on the general impression of others" So far from this being the case I stated my belief that the impression is prevalent among those who *are* original authorities on the Hymenoptera and their parasites, and I also showed that nothing

is advanced by the authorities quoted by Mr Bateson which can be regarded as antagonistic to this impression by any one who knows a little about the working of heredity in insect varieties

A word about "showcases" I hope that no reader of NATURE may be led to think lightly of these as a means of instruction, and as one of the chief objects of a great museum because Mr Bateson states that there is a wrong identification in one at the Royal College of Surgeons, and because of the distinction which he is so careful to draw between these and other cases Some of the most valuable specimens in the world are in "showcases" They form one of the most admirable features in modern museum arrangement, and the best material obtainable is set aside for them This is equally true on the continent and in our own country, where Prof Sir W Flower and Prof Stewart have devoted an immense amount of time and labour to this department, an important recent feature of both their museums being the illustration of the uses of colouring in animals Prof Lankester too is developing the same method of instruction with great success in the Oxford Museum

It is in no way remarkable or reprehensible that four recent writers (Mr Lloyd Morgan, Mr Beddard, Mr Romanes, and myself) concerned with this subject and knowing the care taken in choosing these illustrations, should also make use of some of them in their published works.

One "difficulty" brought forward by Mr Bateson is so futile that I did not allude to it before, and only refer to it now because he repeats it He seems to think that doubt is thrown on the theory of mimicry because *V pellucens* does not resemble a wasp, and yet lives in its nests as if any believer in natural selection maintained that all closely allied forms must defend themselves in the same way!

As to Mr Bateson's statement at the end of his letter that he only intended to draw attention to the matter (and not to hurt me thereby), I can only say that this statement implies an extraordinary want of acquaintance with the niceties of the English language It is so easy to correct mistakes without leaving anything but a feeling of gratitude in the mind of one who has made them, that, in justice to Mr Bateson's intelligence, I am compelled to doubt the accuracy of his memory

Oxford, November 27 EDWARD B POULTON

"A Criticism on Darwin"

I WRITE to protest against what appears to be a growing habit on the part of certain publishing firms of advertising their books in a most misleading manner, viz by selecting any phrase from a notice of the book which may serve to indicate that the writer's opinion on the work as a whole is favourable, whereas, if quoted with its immediate context, the passage would prove the precise opposite For example, I see in NATURE and elsewhere an advertisement of Mr David Syme's book "On the Modification of Organisms, a Criticism of Darwin" (Simpkin, Marshall, and Co), in which I am quoted as having called the writer "a shrewd critic" Standing by itself these words imply that I have somewhere recommended the work as well worthy of perusal The fact of the matter, however, is, that the words occur in a foot note which I added to the proof of my recently published book on "Darwin and After Darwin," for the expressed purpose "of showing the extraordinary confusion of mind which still prevails on the part of Darwin's critics, even with reference to the very fundamental parts of his theory" Elsewhere in the same foot-note I refer to the writer's "almost ludicrous misunderstandings", and conclude by saying that he "shows himself a shrewd critic in some other parts of his essay, where he is not engaged especially on the theory of natural selection." I may now add that the only parts of his essay to which these advertised words apply are those where he treats of the deleterious effects of in-breeding

GEORGE J ROMANES

Animals' Rights

I AM not surprised that you should find my essay on "Animals' Rights" an "absolutely useless" one, for I certainly did not design it to be a congenial hand book for the apologists of Vivisection Nor do I the least object to your drawing what conclusions you like from the premisses laid down by me, even though you seek your justification of vivisection from the very definition that seems to me to be most clearly condemnatory of it. But, as a matter of fact, and not of personal opinion, I beg to point out that you have utterly misrepresented the leading principle of the book, and that the two contradictory definitions of animals' rights, which you attribute to *my* confusion of mind, are in reality the phantom creation of your own On p 9, in referring to Herbert Spencer's definition of *human* rights, I claim for animals a "due measure" (not an equal amount) of the same "restricted freedom"—a claim which by no means prohibits *all* use and employment of animals, as you conveniently assume On p 28 I give, not a second definition, but a repetition and amplification of the one given on p 9, and the "due measure of restricted freedom" is explained as being "a life which permits of the individual development, subject to the limitations imposed by the permanent needs and interests of the community" Surely this is intelligible enough, yet the reviewer has utterly failed to understand it H S SALT

38 Gloucester Road, N W, November 26

Induction and Deduction

MISS JONES has not quite understood me I maintain that definitions should be *arbitrary*, but not necessarily that they should be made *at random* If they are so made it will, as she points out, seldom happen that they turn out useful, or have any real applications, though this would not affect their logical validity if it amused any one to make them and investigate their consequences Such definitions with no real applications are actually made by pure mathematicians The peculiar value of the definitions of geometry consists however in the fact that they have so many real applications, and it is only by a long process of survival of the fittest that a few such happy definitions are weeded out from among the many which lead to nought The definitions of geometry could not now be laid down at random, but they are none the less arbitrary, for they require no support from any *à priori* considerations EDWARD T DIXON

Trinity College, Cambridge, November 28

The Present Comets

I HAVE to notice the following mistake in my letter which appeared in NATURE (vol xlvi p 561) I called comet Brooks, comet "*c*" I now find it should be called comet "*d*"

I have since writing been quite satisfied that the head of comet Swift extends less towards the *n* than towards the *s* (as suggested in my letter) T W BACKHOUSE

West Hendon House, Sunderland, November 26

The Afterglow

AFTER witnessing, with Profs Lyon and Orr, remarkable effects of afterglow on November 27, I waited for the next issue of NATURE (No 1205), in the expectation that similar phenomena would be mentioned as having been seen in the British Isles Curiously enough, the letter on "Afterglow" in that issue comes from Honolulu, dated November 8 It is possible, however, that the effects of volcanic dust from one of the great eruptions of the past summer are now beginning to be noticeable in opposite hemispheres The Krakatão eruption of August 27, 1883, appears to have caused exceptional afterglows in Honolulu on September 5, and in Western Europe by November 9, in the same year

From the top of Killiney Hill, on November 27, at 4 30 p m, we witnessed an extraordinary combination of cloud effects, such as I do not remember having seen since the winter of 1883-4 On the west, dense clouds were forming upon Two Rock Mountain, and streaming down into the hollow of Carrickmines, but beyond them a clear golden sunset, passing above into green and intense blue, was visible above the summits of the hills Fleecy cirrus clouds in the zenith were a delicate pink against clear blue, and this glow extended to all the higher cloud-masses in the east, until the sea itself became rose pink by reflection But in the extreme east the exceptional magenta tints, almost violet, that characterized many of the Krakatão glows, were strikingly apparent, though in part veiled by the low grey cloud of the Channel These effects were at their maximum when the sun had set half an hour, they would doubtless have been of much longer duration but for the near clouds forming on the mountains.

One's thoughts at once turned to the great eruption of Sangir in the Philippines, which occurred, however, as far back as

June 7 of this year Weather and locality have been against my seeing clear sunsets until to-day, when no unusual effects were noticeable, but Mr Bishop's letter makes it possible that in other places similar effects may be observable

GRENVILLE A J COLE

Royal College of Science for Ireland, Dublin, December 4

ELECTRICAL STANDARDS

THE following supplementary report has been presented to the President of the Board of Trade by the Electrical Standards Committee —

To the Right Hon A J Mundella, M P, President of the Board of Trade

Subsequently to the presentation of our former report to Sir Michael Hicks-Beach in July, 1891, we were informed that it was probable that the German Government would shortly take steps to establish legal standards for use in connection with electrical supply, and that, with a view to secure complete agreement between the proposed standards in Germany and England, the Director of the Physico-Technical Imperial Institute at Berlin, Prof von Helmholtz, with certain of his assistants, proposed to visit England for the purpose of making exact comparisons between the units in use in the two countries, and of attending the meeting of the British Association which was to take place in August in Edinburgh

Having regard to the importance of this communication, it appeared desirable that the Board of Trade should postpone the action recommended in our previous report until after Prof Helmholtz's visit

That visit took place early in August, and there was a very full discussion of the whole subject at the meeting of the British Association in Edinburgh, at which several of our number were present The meeting was also attended by Dr Guillaume, of the Bureau International des Poids et Mesures, and Prof Carhart, of the University of Michigan, U S A, who were well qualified by their scientific attainments to represent the opinion of their respective countries

It appeared from the discussion that a few comparatively slight modifications of the resolutions included in our previous report would tend to secure international agreement

An extract from the report of the Electrical Standards Committee of the British Association, embodying the results of this discussion, was communicated to us by the Secretary, and will be found in the appendix to this report

Having carefully reconsidered the whole question in view of this communication, and having received the report of the sub-committee mentioned in resolution 14 of our previous report, we now desire, for the resolutions contained in that report, to substitute the following —

RESOLUTIONS

(1) That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by Her Majesty in Council as Board of Trade standards.

(2) That the magnitudes of these standards should be determined on the electro-magnetic system of measurement with reference to the centimentre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade

(3) That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second

(4) That the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14 4521 grammes in mass of a constant cross sectional area, and of a length of 106 3 centimetres may be adopted as one ohm.

(5) That a material standard, constructed in solid metal, should be adopted as the standard ohm, and should from time to time be verified by comparison with a column of mercury of known dimensions

(6) That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, a limited number of copies should be constructed which should be periodically compared with the standard ohm

(7) That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and submultiples of the ohm

(8) That the value of the standard of resistance constructed by a Committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as 9866 of the ohm

(9) That the standard of electrical current should be denominated the ampere, and should have the value one-tenth (0 1) in terms of the centimetre, gramme, and second

(10) That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0 001118 of a gramme per second may be taken as a current of one ampere

(11) That an alternating current of one ampere shall mean a current such that the square root of the time-average of the square of its strength at each instant in amperes is unity

(12) That instruments constructed on the principle of the balance, in which, by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current whether unvarying or alternating

(13) That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere

(14) That the electrical pressure at a temperature of 15° centigrade between the poles or electrodes of the voltaic cell known as Clark's cell, prepared in accordance with the specification attached to this report, may be taken as not differing from a pressure of 1 434 volts, by more than one part in 1000

(15) That an alternating pressure of one volt shall mean a pressure such that the square root of the time-average of the square of its value at each instant in volts is unity

(16) That instruments constructed on the principle of Lord Kelvin's quadrant electrometer used idiostatically, and, for high-pressures, instrument on the principle of the balance, electrostatic forces being balanced against a known weight, should be adopted as Board of Trade standards for the measurement of pressure, whether unvarying or alternating

ON THE PHYSIOLOGY OF GRAFTING[1]

THE volume before us contains the record of several years of research upon the effects of different forms of grafts (using the term in its widest significance) in the vegetable kingdom.

[1] "Ueber Transplantation am Pflanzenkörper. Untersuchungen zur Physiologie und Pathologie" Von Dr Hermann Vöchting. Mit 11 Lithographierten Tafeln und 14 Figuren im Texte. (Tübingen Laupp, 1892)

Opening with an historical introduction which deals briefly with the development of the art from classical times down to the present day, the author proceeds to indicate the general scope of his own investigations, and to describe the methods of experiment which he employed The immediate problems which he sets himself to solve are contained in two questions which occur on an early page of his book, namely—Is it possible to remove parts of a given plant and transplant them to any other position in the same or a similar plant? And upon this question follows the second—What is the nature of the reaction which occurs between the newly-introduced portion and the surrounding tissues?

But although these form the proximate questions which are to be answered by means of a large number of well-conducted experiments, it soon becomes clear to the reader that the chief interest which attaches to the results obtained depends on their application to the theory of polarity of cells and tissues which Prof Vochting has already put forward elsewhere

The plants chiefly (but by no means exclusively) used in the investigations were *Beta vulgaris* and *Cydonia japonica* The former is of a fleshy and succulent character, whilst the latter is a woody plant which happens to be specially adapted to the various operations of grafting, and, as it is a perennial, it admits of the results of the experiments being watched for a considerable period of time Prof Vochting distinguishes in every part of the plant between a "shoot pole" and a "root-pole," and these he considers to be always present, however small the plant member, or piece of excised tissue, may be The polarity manifests itself at the free surfaces, much as the effects of the magnetism of a bar magnet are visible at its ends, and moreover, just as the pieces of a broken magnet are themselves duly polarized, so also fragments of tissue exhibit relations of polarity identical with those characteristic of the organism from which they were derived

The first precaution necessary to secure success in grafting is to respect the existences of the shoot- and root-poles, and to insert the scion in such a way as to bring its poles into due correspondence with those of the stock Acting upon this principle it is found that, generally speaking, any member may be grafted on any other member unless there is some special reason to the contrary, such as may be connected, for example, with nutrition or water-supply The leaf of the beet will "take" if grafted on a root, and *vice versa*, and it was also found that it was possible, in the case of roots with diarch bundles, to effect a union even when the xylem planes in the two portions were made to cross each other at right angles, analogous results were also obtained with leaves Hence the author concludes that there is no inherent fixity in the organization of plants which predetermines a definite sequence of the chief members of which they are composed

Experiments were made with the object of determining the mutual reactions between the stock and the scion, and the conclusion arrived at is that beyond such changes as may be referred to nutritional and similar causes, the two remain unaltered, at least in so far as their specific characters are concerned Prof Vöchting criticises unfavourably the various alleged cases of the so-called "graft-hybrids," and points out that even in one of the best authenticated examples, that of *Cytisus Adami*, all attempts to produce the hybrid afresh have resulted in failure.

The most interesting part of the book is occupied with the account of researches into the behaviour of transplanted portions of tissue, the direction of whose "polarity" does not coincide with that of the parts into which they are introduced. When the inserted portion of tissue is rotated on its longitudinal axis so that its own tangential surfaces are applied to the radial ones of its new host, difficulties arise in the accomplishment of a complete union, and these difficulties are further increased to a maximum when the tissue is put in upside-down, so to speak, that is with its own poles presented to *similar* poles in the stock A great number of experiments were instituted to investigate these reactions, but space forbids any attempt to do more than briefly summarize the most important points In the case of *Cydonia japonica* a ring of rind was cut out of a twig and replaced in the reversed direction. In many cases the twigs behaved as if the tissue had not been restored at all, simply dying, whilst in others a subsequent healing took place. This healing was accompanied by a swelling at the upper junction, together with the appearance of a ridge of tissue which was formed along the longitudinal suture of the ring from above downwards and was derived from the cambium of the ring, and not by an ingrowth of callus from the uninjured cortex of the twig, as might perhaps be supposed In this way connection between the interrupted rind was re-established, and growth recommenced But both at the edges of the tissue-ridge, and also between it and the original underlying xylem, the cell elements were found to be disposed in a remarkable manner, forming curved unions with the cells of the healthy tissues. For the histological details the reader is referred to the original treatise, suffice it to say that Prof Vöchting believes that he has found in the appearances thus presented, additional evidence for the validity of his theory of the polarized condition of living tissues He conceives of these polarities as properties which are the expression of the innermost relationships existing between the constituents of which cells are built up He further regards the polarity of any tissue as irreversible when once the direction has been imparted to it, and he finds justification for this view not only in the details of his own experiments on grafting, but also in the results of investigations conducted by Kny and others, on the effects of compelling parts of plants to grow in a reversed position After discussing some of the objections to his theory, without, however, disposing of them all, the author concludes by stating, with considerable reserve, some of the wider applications of his theory in explaining geotropism and other allied phenomena.

The book certainly forms one of the most important of the recent contributions to plant physiology, and the experimental details are well illustrated in the eleven plates which accompany the text, whilst the diagrams in the body of the work serve to render the author's theoretical views more intelligible J. B F.

NOTES

A GOLD MEDAL is to be presented to M Pasteur on December 27, his seventieth birthday

ON Monday Lord Durham laid the foundation stone of a new wing of the College of Science, Newcastle, which, like the College of Medicine in the same city, is a branch of the Durham University The College of Science was established at Westgate hill, Newcastle, in 1871. Lord Armstrong laid the foundation stone of the present premises at Barras Bridge in 1887, and in the following year the existing wing was opened by the Marquis and Marchioness of Lorne The success of the institution is strikingly indicated by the fact that the increase in the number of students has rendered a new wing absolutely necessary

DR. WERNER SIEMENS, the well-known electrical engineer, died at Berlin on Tuesday. He was seventy-six years of age.

MR. W. H. PREECE, F R.S, has been appointed a member of the Royal Commission on Electrical Communication with Lighthouses, &c., in the place of Mr Edward Graves, deceased.

MR W MATTIEU WILLIAMS, who had a considerable reputation as a metallurgist and a popular writer on scientific subjects, died at his residence, near Willesden, on November 8 He was in his seventy fourth year Among his writings ar his well-known books on "The Fuel of the Sun," "Science in Short Chapters," and "Through Norway with a Knapsac k"

WE have to record the death of two distinguished Continental cryptogamists, Dr F v Thumen, the well known mycologist, formerly Director of the Chemico-Physiological Experiment Station at Klosternenberg, and Dr C M Gottsche, of Altona, one of the authors of the *Synopsis Hepaticarum*, and one of the leading authorities on Mosses and Hepaticæ, in the eighty-fourth year of his age

The Master and Fellows of Gonville and Caius College, Cambridge, have elected as Honorary Fellows the following graduates of the college —Alexander Henry Green, F R S, bracketed sixth Wrangler, 1855, formerly a Fellow of the College, late Professor of Mathematics, Yorkshire College of Science, now Professor of Geology, Oxford, Arthur Ransome, M D, F R S, First class Natural Sciences Tripos, 1856, Physician to the Manchester Hospital for Consumption and Diseases of the Throat, and George John Romanes, F R S, Sir Robert Rede's lecturer, 1883, late Professor of Physiology in the Royal Institution of Great Britain

AN important conference on technical education was held at Newcastle on Saturday It was summoned by the Technical Education Committee of the Northumberland County Council Sir M White Ridley, the Chairman of the Council, said that the scheme of the Technical Education Committee, generally speaking, had opened out two progressive educational roads from the elementary day school onward—first, for day scholars, by means of scholarships, and secondly, for evening students by a graduated system of classes The work in progress under that scheme had already been very extensive As regarded agriculture, there had been courses of lectures on manuring land, poultry-keeping, farm stock, dairy work, &c Educational courses had been given in mining, mechanics, electricity, engineering, ship building, &c As regarded the fishermen also, a very successful method had been adopted of teaching the men a few plain scientific facts with regard to coastal navigation, the habits of fishes, and so on. After the delivery of the Chairman's speech the Committee's scheme was carefully discussed.

PRIZES and certificates in connection with the City and Guilds of London Institute will be presented on Monday, December 12, at Merchant Taylors' Hall, Threadneedle street, by Mr William Anderson, F.R.S The Lord Mayor will preside.

AT the General Monthly Meeting of the Royal Institution on Monday, the special thanks of the members were returned to Mr Ludwig Mond for a donation to the fund for carrying on investigations on liquid oxygen

MR STREETER held a reception on Saturday at 18 New Bond Street for the first display of sapphires from the Montana mines At the same time an assortment of chrysoprase jewels was exhibited, and also a black diamond, said to be the largest yet discovered Mr Streeter also showed, among other things, a collection of different specimens of pearl-bearing oyster shell, and some curious formations of pearls in shell and loose, and in a variety of natural colours

IN the current number of the *Geological Magazine* it is noted that Mr Joseph E Carne, Curator of the Mining and Geological Museum, Sydney, New South Wales, who so ably assisted the late Mr. C S Wilkinson during the Mining and Metallurgical Exhibition at the Crystal Palace, Sydenham, in 1890, has been appointed by the Minister of Mines to the post of Geological Surveyor Mr Carne entered the service of the New South Wales Government in 1879

THE French Association for the Advancement of Science has received from an anonymous donor the sum of 600 francs, to be given in two prizes (of 400 and 200 francs), to the authors of the best memoirs containing an investigation, according to local documents, of the frequency of rabies, and the prophylactic measures in operation in a department of France, *la Seine excepted*, or in a region (two or three departments) of France or of Algeria The statistical figures must relate to ten years at least, and comprise the results of 1892 Manuscripts to be sent to the secretary in Paris before March 31, 1893. The following points are noted for investigation —The number of rabid animals, of dogs, of persons bitten, and dead through rabies, also of those vaccinated at the Pasteur Institute separate the cases of rabies in large towns from those in the rest of the department, measures of sanitary police, their effect and difficulty of application, causes of more or less frequency of rabies, and of vaccination, measures taken in frontier departments, &c

DR B PASQUALE has undertaken a study of the phenomena and causes of the very destructive disease of the vine known as "mal nero,' his observations having been made chiefly in Sicily The disease makes its appearance in the form of black spots and streaks on the leaves Dr Pasquale finds it to be always accompanied by a Schizomycete, which he believes also to be its cause, and which is parasitic, especially on the tissues rich in protoplasm and in other plastic substances, such as the cambrium, the medullary rays, the cortical parenchyma, and the soft bast of the axile organs

THE *Botanical Gazette* states that, in a report to the Cornell University, Prof L H Bailey firmly establishes the commercial value of the electric light for certain winter crops, especially for lettuce Certain kinds of plants, which are injured by the direct rays of the light, are not injured, but may even be benefited, when the light passes through a clear glass globe or through a glass roof Auxanometric records appear to show that the light accelerates growth, but does not change its normal periodicity This is in harmony with the observations of Prof G Bonnier, recorded in the *Comptes rendus*, who finds that the electric light promotes the formation of chlorophyll in all kinds of plants, both woody and herbaceous

THE third appendix, 1892, of the *Kew Bulletin* has been issued It consists of a list of the staffs of the Royal Gardens, Kew, and of botanical departments and establishments at home and in India and the colonies, in correspondence with Kew

M EDOUARD BRANLY, Professor of Physics at the Ecole Libre des hautes études, Paris, writes to us to complain that experiments made by him are attributed to Mr Dawson Turner in our account of "Physics at the British Association" (NATURE, August 18, p 384) We learn that in Mr. Turner's paper, and in the condensed report furnished by him for publication, full justice was done to Prof Branly's work The reference to Prof. Branly was unintentionally omitted when the report was being cut down for NATURE

MESSRS MACMILLAN & CO will publish immediately a new book by Professor Oliver Lodge, entitled "The Pioneers of Science" In this volume, which will be fully illustrated with portraits and diagrams, the author describes in popular language the history and progress of Astronomy His aim has been to state scientific facts and laws as simply as possible, to present in turn a living figure of each Pioneer, and to trace his influence on the progress of thought.

DURING the past week barometric depressions have reached our western coasts with considerable frequency. As these dis-

turbances were passing away from our islands, sharp frosts occurred in the north, where the shade temperature fell as low as 13° in the north of Scotland on Thursday, December 1 The gales which accompanied the depressions were confined more particularly to the north and west On Saturday, the 3rd instant, a large cyclonic disturbance appeared from off the Atlantic, and in the rear of this cold north westerly winds set in with snow or hail showers generally, in many parts of the country the snow was sufficiently heavy to interfere seriously with traffic The temperature continued to decrease, the highest daily maxima being generally below the average for the time of year, and at places in the north and north east of our islands the maximum thermometer at times did not rise above the freezing point For the week ended the 3rd instant the official reports show that the rainfall was greatly in excess in Scotland, and rather so in the south of England and some of the western districts, but in the eastern parts of Great Britain, and in the north of Ireland, there was a deficiency In the south-west of England the deficiency, from the beginning of the year, is still very great, being 22 per cent of the average amount

MR H C RUSSELL, in his presidential address to the Royal Society of New South Wales, mentions a very curious drift of a "current bottle" thrown from the Austrian man-of-war *Saida*, about half-way between Sydney and New Zealand This bottle found its way through twelve degrees of latitude and four of longitude to the coast of Australia, two miles north of Tweed River, where it was found just eleven months after it was thrown into the sea. Mr Russell states that from what is known of the currents, which set strongly to the south along the coast of Australia, it seems impossible that it could have travelled direct, and that it was therefore probably carried east ward to the coast of New Zealand, and thence northward towards New Caledonia, until it got into the current setting from there to the coast of Australia, a journey of at least 2,500 miles in 335 days, and doubtless subject to many deviations which made its course longer and all the more surprising

M W PRINZ, secretary of the Belgian Microscopical Society, has published an interesting paper on filiform inclusions in the quartz of St Denis, Mons, which strangely simulate organic structures He has at the same time discussed the origin of moss agates, and has repeated the experiments with colloid silica and certain salts by which very similar appearances are produced The paper, which is illustrated with a plate, is a valuable contribution to the literature of a very interesting subject

MR W HOLLAND contributes to the December number of the *Entomologists' Monthly Magazine* some good practical hints on sugaring Moths, he says, often come more readily when sugar is applied to the twigs and branches of the trees they feed upon, or twigs of something near their food-plant, than they will to sugar placed on the trunks of trees, *Xanthia citrago*, for instance, will hardly come at all to sugar put on the trunk of the lime tree, an occasional one only will be got in this way, but by sugaring below the tips of the outermost branches all round the tree Mr Holland generally finds about fifty on one tree, besides other species In the case of *Xanthia aurago* again, the best place to sugar is along the outside of the beech wood beneath the ends of the overhanging branches, or on the twigs of the hedge below them Mr Holland has repeatedly taken about 100 in a night in this way, when trunks sugared inside and outside the wood have not yielded one specimen Other things may be got in the same way by selecting the place according to the species wanted. Among other points to which he calls attention is the necessity of recognising early what is going to be a species of the year, for every year brings some particular kind more plentifully than usual The sugar Mr Holland uses is "Egyptian raw," a date sugar This is very dark and strong stuff, sand like, and free from lumps, and it mixes easily without boiling He simply mixes it with beer, and then adds a drop or two of essence of pears just before starting out There is rum enough in good sugar, and to add more is only to make the moths drop off before they can be bagged "Jamaica foots" is a good sugar too, but it is lumpy and needs boiling Old black treacle will do fairly well as a bait, but "golden syrup" Mr Holland believes to be a fraud Beet-root sugars, or refined sugars, are of course bad, and if he happens to be in a place where he can get only these, then, and then only, he adds rum

THE second volume of the Transactions of the Leeds Naturalists' Club, to which we referred last week, includes an interesting paper on the structure and life history of a fungus, by Mr Harold Wager, assistant lecturer and demonstrator in biology, in the Yorkshire College, Victoria University The paper deals with a small microscopic fungus, *Peronospora parasitica*, as a type of the fungi Mr Wager points out that, although in some respects this may not be the best type for the purpose, it has the advantage of having a comparatively simple structure and method of development easy to understand, and serving as an excellent introduction to the morphological study of the fungi This type is also the more interesting because many structural details, which are fully described by Mr Wager, have been more fully worked out in it than in any other The paper is carefully illustrated, and the author gives a useful summary of the methods employed in the examination of the various structures he mentions

A NOVEL utilization of aluminium is that for the construction of aluminium slate pencils Major von Sillich, of Meiningen, found that aluminium gives a stroke on a slate, and a German company has undertaken the manufacture of pencils based on that fact They are 5mm thick and 14mm long They need no pointing, and are well nigh inexhaustible and unbreakable The writing, which is as clear as with ordinary pencils, requires a little more pressure It can be erased with a wet sponge.

A COLORIMETER for comparing the intensity of colour in a solution with a standard solution has been constructed by Papasogli It consists of two graduated cylindrical vessels of equal diameter, through which light is transmitted from below A vertical telescope fixed above the tubes shows the two halves of the field equally illuminated if the amounts of coloration are the same If they are not, the heights of the liquids in the tubes can by a simple contrivance be so regulated that the colours have equal shades Under these conditions, the concentration of colouring matter is inversely proportional to the length of the column of liquid tested

THE Trinidad Field Naturalists' Club has held its first annual meeting, and has evidently good reason to congratulate itself on its success, which has surpassed the highest expecta tions of the members Mr Caracciolo, the chairman, in his presidential address, reminded the club that the gardens, plains, mountains, and rivers of Trinidad swarm with animal forms, about a good many of which very little is yet known.

THE latest instalment of the Transactions of the Institution of Engineers and Shipbuilders in Scotland includes the address by Mr Robert Dundas, president, at the opening of the pre sent session. Speaking of railways, Mr. Dundas said that a continual improvement in rolling stock generally can be noted Larger and more commodious carriages are gradually taking the place of the smaller ones, and there is a marked increase in the application of the bogie principle, which does well, and makes an easy running carriage when properly constructed

"Long carriages," said Mr Dundas, "cannot be built to go round ordinary curves without either a bogie or radial axle; and between the two experience leaves very little doubt as to which is the better. The radial axle is an awkward arrangement, and does not act with the same smoothness as a well constructed bogie with properly balanced springs to regulate its motion, and a bogie of short wheel base is not so good as a long one, the wheel base should always be more than the gauge to produce good results There is no better test to determine what is good or bad in rolling stock than the effect on the permanent way"

A valuable paper on the copper resources of the United States, read by Mr James Douglas before the Society of Arts on November 30, is printed in the current number of the Society's journal Mr Douglas notes that though for many years no new copper mine has been opened, the larger and richer ones, which have been able to maintain existence in the face of depressed prices, are directing their efforts, not so much towards increasing their capacity for production as towards reducing the cost of reduction, saving, as far as possible, the precious metals associated with their ores, and securing for themselves the profits which have heretofore been made by the refining companies, to whom they sold their furnace material "The effect of this change of policy," said Mr Douglas, "may tell upon the market It certainly will affect the copper refineries of this country and the continent It would seem, therefore, that the era of rapid expansion is drawing to its close, and a healthier one of economical treatment is being inaugurated The demand for copper is so great, that, if this policy be pursued by the large existing mines, there will be room for the appearance of new competitors, without imminent risk of over-production"

Mr W J L Abbott contributes to the new instalment of the Proceedings of the Geologists' Association an interesting note on the occurrence of walrus in the Thames valley *Trichechus rosmarus*, Linn, has been recorded from several places on the east coast, from the Dogger Bank, and from the peat near Ely In the Thames valley it was discovered at a depth of 33 feet 2 inches during the excavations for the new London Docks It was, however, considered to have "tumbled down from above," and so was passed by In 1888 Mr Abbott saw a tusk taken out of the gravel in the course of excavations for a wharf in Upper Thames-street, it was associated with bones of pachyderms Although he felt sure of its identity, he was unable to procure the specimen, probably because his eagerness to obtain it manifested itself to the workman, who immediately affected that he would not part with it. Not long afterwards, in an excavation between Leadenhall and Fenchurch streets a number of bones were taken out of the gravel which underlies the peat, which in turn underlies the Roman layer The upper part of the gravel is stained somewhat by the peat, as are the contained bones Amongst the latter there was a large part of the skull of a walrus, with one tooth still left *in situ*, the others having been destroyed in the rough usage to which it had been submitted in bygone times The state of preservation is seen to be exactly similar to that of the other bones found with it, while its position, Mr Abbott thinks, leaves no question as to its Pleistocene age He holds therefore that in future *Trichechus rosmarus* should be added to the Thames valley fauna

At the meeting of the chemical section of the Franklin Institute on October 18, Mr. Palmer read a note on a lilac colour from extract of chestnut He said that in experimenting with a commercial extract of chestnut wood, with the idea of making galloflavine therefrom, he had obtained an unlooked-for result. The extract was somewhat fermented; that is a part of the tannin had been changed into gallic acid; and the design was to convert this gallic acid into galloflavine by the usual method A solution of the 51° extract was made strongly alkaline with potash, and subjected to the action of a stream of air for about ten hours The temperature, meantime, was kept below 50° F At the end of the period of oxidation the potash was neutralized with acetic acid The solution so obtained was tested for galloflavine by working therein cotton and wool yarns with the addition of potash alum While no yellow colour was obtained, a clear, bright lilac was developed on both the animal and the vegetable fibre The body giving this colour has not as yet been separated from the oxidized extract

A book entitled "Mind and Matter an Argument on Theism," by the Rev James Tait, of Montreal, has been so well received that a third edition, revised and enlarged, has just been issued (London C Griffin and Co) Whatever may be said of Mr Tait's theology, he has a good deal to learn as to the temper in which the consideration of scientific problems should be approached It seems a little foolish, at this time of day, to talk about the "horrible plaudits" which "have accompanied every effort to establish man's brutal descent"

A paper embodying various suggestions to travellers was read at the June meeting of the Queensland branch of the Royal Geographical Society of Australasia by Mr J P Thomson, the honorary secretary of the Society The paper, revised and enlarged, has now been reprinted from the Society's "Proceedings and Transactions."

The Society for Promoting Christian Knowledge has issued a new edition of "Sinai from the Fourth Egyptian Dynasty to the Present Day," by the late Major H S Palmer The little book has been revised throughout by Prof Sayce

Messrs. Newton & Co have issued a catalogue of science lanterns, magic lanterns, dissolving view apparatus, and lantern slides, manufactured and sold by them The catalogue is accompanied by a supplementary list for season 1892-93

The additions to the Zoological Society's Gardens during the past week include a Lesser White-nosed Monkey (*Cercopithecus petaurista* ♂) from West Africa, presented by Mr W H Henniker, two Great Kangaroos (*Macropus giganteus* ♀ ♀) from Australia, presented by Sir Francis Wyatt Truscott, J P., F Z S, a Common Chameleon (*Chamaeleon vulgaris*) from North Africa, presented by Miss Truefitt, a Sykes's Monkey (*Cercopithecus albigularis* ♀) from West Africa, deposited

OUR ASTRONOMICAL COLUMN

Comet Holmes (November 6, 1892).—Computations of the orbit of this comet show now that it is an elliptic one, the period extending to 6·78 years, very nearly the same as that of Wolf Comet, 1884 III–1891 II The time of perihelion occurred on June 20·7357 of this year, and the comet's orbit may be mentioned as lying wholly between those of the planets Jupiter and Mars

The following elements and ephemeris are due to Mr. A. Berberich, and are derived from observations made on November 9 (Karlsruhe), November 18 (Hamburg), and November 25 (Berlin) —

Elements

A NEW COMET (BROOKS, NOVEMBER 20).—On the evening of November 20 a telegram was received at Kiel announcing the discovery of a new comet by Brooks on November 20. Its position on November 20·875, Greenwich M.T. was given as R.A. 12h. 57m. 40s., Decl. +13° 25′. Its physical appearance was described as "circular, diameter equal to 1′, brighter than a third magnitude star, some eccentric condensation, no tail."

From observations made on November 21, 24, and 26, Prof. Kreutz has found the following elements and ephemeris, which has been communicated by a Kiel circular post-card:—

Elements.

T = 1893, January 6·953, Berlin M.T.

ω = 84 24·5
Ω = 185 10·7
ι = 143 18·6
$\log q$ = 0·08130

A NEW COMET.—The comet which on the 24th was discovered by Mr. Freeman is now supposed most probably to be a nebula.

THE CHANNELS OF MARS.—In our Astronomical Column for November 17 we referred to the most recent hypothesis that had been put forward with respect to the doubling of the channels on the surface of Mars. Another suggestion has lately come under our notice, and this, although explaining the phenomena in quite a different way, has a point or two in its favour. This explanation appeared in the *Shanghai Mercury* on October 14, and was written by Mr. T. W. Kingsmill, the following being a brief summary of the main points:—

As Mars revolves round the sun, under the rule of gravitation, she must have tides on her surface, and since her moons are not sufficiently large to cause any sensible rise, her tides must be mostly solar. Now the best views we have of this planet is when he is in opposition, that is when we are interposed between him and the sun, so that we should always see him best at high tide. The writer then makes rather a strong point of the great eccentricity of the orbit of Mars, and the consequent heavy fall which he makes when plunging towards the sun. Situated further from the sun than we are, Mars of course must be reckoned as an older member of our system, and since he is smaller than our earth, it is only natural that his surface crust would be thicker than ours. Granting this then the internal pulp would not have such a power to compensate for this rapid fall, as our earth does internally, for there would not be much of it, so that an external compensation, assuming the crust to be too thick to alter its form, would have to take place at the surface. On the surface of course the water is the only available power, therefore we should expect, to put it in Mr. Kingsmill's own words, "that the water in the ocean would be projected into the Martial hemispheres, and as the planet approached the sun, solar tides would sweep round the planet, that the canals should sometimes appear and sometimes be duplicated . . . . is only what *à priori* might be anticipated."

Those interested in this question will be glad to hear that M. Stanislas Meunier (*Comptes rendus* for November 21, No. 21) has been continuing his experiments on this subject, which we referred to a fortnight ago. He finds now that by employing a metallic sphere instead of a polished mirror, and covering its surface with the veil as he did his former experiments the results are more striking, and bring out more clearly the phenomena really observed on the planet's surface.

ASTRONOMY AND ASTROPHYSICS.—The November number of *Astronomy and Astrophysics*, among many of its interesting articles contains one by Prof. Pickering on the lunar atmosphere, which will be read with much interest. Accompanying the article is an illustration of the recent occultation of Jupiter, at which time a dark band tangent to the moon's surface but on the planet was both observed and photographed. Prof. Coakley writes on the "Probable origin of Meteorites," the conclusions which he draws referring their origin to prehistoric lunar eruptions.

Prof. Hale, in addition to several articles on solar physics, describes generally the proposed new giant Chicago refractor, and from all accounts the observatory when finished and ready for work will be operated by simply pressing buttons; the observing chair will be entirely eliminated, the floor of the observatory, capable of motion in the vertical direction, serving the purpose. Mr. W. W. Campbell gives rather a lengthy account of his observations on the spectrum of the late Nova, and the result may be summed up in the words, "While the hypothesis of two bodies quite generally satisfies the observations, and has the further very great advantage of simplicity, there are a few not unimportant points furnished by the photographs which favour the existence of three or four bodies, two or three yielding bright line spectra and one a dark line spectrum."

A NEW OBSERVATORY.—M. S. de Glasenapp recently announced to the French Academy of Sciences that a new astronomical observatory has been erected at Abastouman, in the government of Tiflis. The observatory has been called Géorgieïoskaja, in honour of its founder, and it is situated at a height of 1393 metres above the level of the sea, its terrestrial co-ordinates being latitude + 41° 45′ 43″ longitude, east of Paris 2h. 41m. 58·5s. At present it is provisionally supplied with a refractor of about nine inches belonging to the St. Petersburg University. Work has already been begun, and from all accounts the situation seems to be most favourable, many double stars measures having been obtained, which in ordinary circumstances are accounted very difficult objects with such an aperture. The observatory was opened on August 23 of this year, and up to November 5 as many as 400 double stars have been measured, omitting observations of the total lunar eclipse and of some phenomena of Jupiter's satellites.

GEOGRAPHICAL NOTES.

DR. KARL DIENER has returned to Vienna from his geological expedition in the Himalayas, which has resulted in important additions to the data available for a geological description of the great mountain system. In June the expedition commenced work in North Kumaon, crossing the Utadurrha Pass (17,600 feet), and after more than three months spent amongst the border ranges of Tibet, returned to India by the valley of Alaknanda. For a month the party never camped at a less height than 14,500 feet, and the highest summit reached was over 19,000 feet.

DR. NANSEN is threatened with a serious rival in Lieutenant Peary, who has obtained leave from the United States Navy for three years to be spent in Arctic exploration. The base of his projected journey would be the farthest point reached by him on his recent journey in Greenland, and "an incidental object" would be to reach the pole by travelling over the frozen surface of the sea which he believes to surround it.

FRIEDRICH HELLER VON HELLWALD, well known as a writer on geography and ethnology, died on November 1, aged fifty years. He was born at Padua, and grew up with an equal knowledge of German and Italian, a fact to which much of his ultimate success as an author may have been due. He was an officer in the Austrian army, but devoted most of his time to historical research and literary work. His earliest work, "Amerikanische Völkerwanderung," appeared when he was twenty-four years of age, and later he wrote on the Russians in Central Asia, the native people of various parts of Asia, the history of civilization, and other subjects. His "Die Erde und ihre Völker" formed the basis of Stanford's "Compendium of Geography and Travel." For many years Hellwald edited the geographical journal *Das Ausland*.

CAPTAIN H L GALLWEY, vice-consul for the Oil Rivers Protectorate, gave, at the meeting of the Royal Geographical Society on Monday, a detailed account of his travels in the Benin country, of which notice has already been taken in this column (vol xlvi p 65) The fact that some of the deltaic streams are clear and transparent, while the Niger water is very muddy, makes it probable that they are small independent rivers An account of a visit to Benin city gives some idea of the decadence of native West Africa since the time of the early writers on the region, if these were to be trusted

MR F WILKINSON read a paper on the Kalahari desert, at the same meeting It described a waggon drive through part of the desert area in company with two others, whose names were disguised under initials. Although great scarcity of surface-water was found, and the draught oxen and horses had some times to be watered from "sucking holes," where natives sucked up the water and filled the buckets from their mouths, the land was fairly well grassed in most parts, and Mr Wilkinson believes it possible that it may subsequently become useful for grazing A rough geological survey of the district passed over was made Granite covered a large part of the surface, and appears to be the bed rock of the whole district examined Hard crystalline siliceo-calcareous beds and highly altered ferruginous shales, as well as quartzite were also found, but vast accumulations of blown sand masked the true geological structure in almost every place

THE Geographical Society of California claims to have achieved "an immense success" The Society was incorporated on December 11, 1891, for "the acquisition and dissemination of scientific geographical knowledge," and has already achieved a membership of 400 Monthly lectures have been given, and a bulletin has been published We hope that a society which has begun so well will fulfil the Latin proverb which it has adopted for its motto, "*Vires acquirit eundo*"

THE ANNIVERSARY DINNER OF THE ROYAL SOCIETY

THE anniversary dinner of the Royal Society was held on the evening of St Andrew's Day at the Hôtel Metropole It was more largely attended than any previous anniversary dinner, covers being laid for about 230 The chair was occupied by the President, Lord Kelvin On his right were Mr Shaw Lefevre, M P., Sir James Paget, the Italian Ambassador, Prof Raoult (medallist), Sir H Roscoe, M P, Sir James Lister, Lord Justice Lindley, Sir B Samuelson, Sir A Moncrieff, Sir U Kay-Shuttleworth, M P, Sir C E Bernard, the Dean of St Paul's, Mr. John Hutton, and Sir H Acland On the left of the chair were Mr Arthur Acland M.P, Prof Huxley, Mr James Bryce, M P, the Swedish Minister, Lord Ashbourne, Sir G Stokes, the Treasurer of the Society (Sir John Evans), Mr Alma Tadema, Sir R E Welby, Mr Herbert Gardner, M P, Sir Godfrey Lushington, Mr Bryant, and Dr Mackenzie. The vice-chairs were occupied by Sir B Baker, Prof Roberts Austen, Lord Rayleigh, Prof M Foster, Sir A Geikie, Mr Norman Lockyer, Dr Pye-Smith, Prof Vines, and Mr Rix (assistant secretary) The first toasts were "The Queen and the Prince and Princess of Wales," and "Her Majesty's Ministers and the Members of the Legislature"

Mr Shaw Lefevre, in the course of his reply to the latter, said that men of science as a rule were unwilling to abandon the quiet fields of research in order to launch on the stormy seas of politics, and if they were willing, they were too philosophical to swallow the creeds of either political party He thought that the two older Universities might help in this matter, and do more to justify their right of representation by emulating the example of the London University in returning men of science to Parliament If there was any man in the country whose presence in the House of Commons would add to its quality and power, it was Prof Huxley

Mr. Acland, in proposing the next toast, said,—I have to propose to those who are here present, and who do not bear the title of "F R.S," the toast of "The Royal Society"—a society ancient, independent, distinguished, and most beneficent in its operations during a course of more than two centuries. Why I, a mere politician, have been selected to propose this toast I do not know. In looking over a list of the late proceedings of your society a day or two ago, I tried to discover some links between yourselves and the Education Department, over which I preside I came across the words, "On character and behaviour," and I thought that that looked like the kind of language which we employ in our instructions to her Majesty's inspectors of schools But it was not so. The subject to which the words had reference was "on the character and behaviour of the wandering cells of the frog, especially in relation to micro-organisms." I feel that I must fall back upon some more substantial links than that, and I fall back upon the fact that I have the honour to preside over certain institutions in which members of your society are engaged There is the Dean of the Royal College of Science at Kensington, Prof Huxley, and your foreign secretary, Sir Archibald Geikie, and, altogether, including those who examine for us from time to time, there are something like thirty members of the Royal Society who are connected with those institutions, and I consider it a very high honour to be linked with institutions with which they are connected Whether some of my friends at Kensington look on their connection with the State in the same light, I do not know When I have the honour of going over the laboratories of my friends, Prof Thorpe and Prof Rucker, I am inclined to doubt it But as far as the present connection with the State goes, the Royal Society do most admirable service They act as unpaid judges for the administration of a sum of £4,000, which the State would find it very difficult to administer on its own account, and they do the work in so impartial and admirable a manner that no man in his senses could complain There is one other link between us There are present here a large number of men who are interested in the work of education, and I think they will agree with me that we have one great task before us Between the Universities and the University Colleges with which most of them are connected and the great sphere of elementary education there lies a large region, at present unorganized and chaotic, which we want to organize and bring into working order as soon as possible There are many men of science in these colleges who often greatly regret to find willing lads, with the highest scientific capacity, brought under their notice and care, whose only lack is a lack of adequate educational preparation for their work It is that which we want to remedy, and if I am enabled to take however humble a share in remedying it, I shall be proud of the task We want to engage in the task of the reclamation of waste, and one of the most serious of all wastes is the waste of intellect For those lads who go to our colleges in every part of Great Britain and Ireland we want to hold out one great possible goal—the blue riband of science—the title of Fellow of the Royal Society You at any rate in your scientific honours have no distinction of class, and, as your medallists to day will testify, no distinction between one country and another You regard all as equal when you adjudge your honours to the fittest men to bear them I connect with this toast the name of your distinguished President, Lord Kelvin It was truly said some nine years ago, when his claims were urged for the Copley Medal, "there is scarcely a branch of physical science to the substantive advantage of which he has not contributed", and I understand that while he has touched both the highest and the most abstruse subjects, he has not failed to condescend even to humble matters like the domestic water tap Among those of you who know far better than I do what Lord Kelvin has done, both for abstruse science and for the welfare of mankind, there can be no limit as to the value of his work to future generations I am sure that he himself cannot possibly say how great the value of what he has done may be in the far-off future But I understand from Sir Archibald Geikie that your president has attempted to put a limit to the inquiries of the geologists, when they look into the backward past. He has definitely said that in looking backwards they must not go beyond the moderate limit of twenty million years I understand that this is a grievance on the part of the geologists, but I hope that the President will not give unnecessary pain to his geological friends In the draft of the preamble of your charter—it was drafted by Sir Christopher Wren—it was said Fellows of the Royal Society, by "their labours in the disquisition of nature, would try to prove them selves real benefactors of mankind." I give you the toast of "The Royal Society," coupled with the name of Lord Kelvin, and I assert that your present President has done his part in proving himself a benefactor of mankind.

The Chairman, in replying, said,—I thank you very heartily for the kind manner in which you have received this toast. I feel the honour you do me, but I also feel my incapacity to say

what ought to be said for so great an institution I can only say in my own way that I believe the Royal Society, as an institution, has up to the present time persevered in well doing, and had been successful in its efforts The Royal Society has certainly endeavoured to carry out the objects of its institution—namely, to inquire into natural knowledge and the improvement of it The mode of carrying out that object was carefully considered, no doubt, by those who founded the Royal Society, and they determined to hold regular meetings, partaking somewhat of the character of a debating society—meetings where discussions could be raised by questions presented, and the truth arrived at thereby That object has been carried out from the inception of the Society to the present day, and the society has been imitated by other societies over a large part of the civilized world Indeed, the Royal Society itself only followed in the path of other learned societies in Italy, which had determined that by personal discussion of questions in regular meetings truth might be arrived at which otherwise might be lost We often find complaints that meetings of scientific societies are unsatisfactory We have even complaints that the important duty, the publication of their proceedings for the rest of the world, is not altogether ideally perfect Some who desire the progress of science above all, and heartily wish success to the Royal Society, think that the society ought to be a body for merely recording and indexing the work that has been done all over the world That is a part of the work of the Royal Society which is not neglected The council has had most anxious, careful, and laborious consultations from year to year with reference to this work—not only as to the publication of its own transactions and proceedings, but as to the cataloguing and indexing of the proceedings of scientific bodies and scientific workers all over the world One very important part of the work of the society consists of the cataloguing of all scientific papers published, and a very dry and fatiguing subject it is to work upon The difficulty here is *embarras de richesses* To get the titles only of these papers is itself a truly Herculean task If the Royal Society had not only capacity, but had also great funds at its disposal, it would make short work of this task It would not only index, it would publish the papers and would put them in such a form that any one could find his own particular subject at once, and the particular volume and page in which it was treated This is an exceedingly difficult subject, but the first necessity is funds, and if those were supplied all the rest would follow The publishing and indexing, however, is not the only work of the society The life and soul of its work is in its meetings and discussions, and whoever has not felt the stimulus of attending those meetings has hardly yet found out the spirit of scientific enquiry For myself, I say the fact that we can attend meetings of the Royal Society, and hear papers on subjects very far removed from the subjects of our every day work, is a stimulus which is of the highest value The worker who has heard what other people are doing goes back to his work with something which may help him in it, which, at any rate, brightens his life, and makes the drudgery and heavy work necessary for success in any scientific investigation less irksome and dry For myself I may say that my connexion with the Royal Society, extending over a great many years, has been one of unmixed benefit and pleasure, and has given to me some of the happiest of those pictures of knowledge and memory the possession of which constitutes so much of the delight of life Mr Acland remarked upon my having been hard upon the geologists I do not think that I have actually been so I do not believe in one science for the mathematician, another for the chemist, another for the physicist, and another for the geologist All science is one science, and any part of science which places itself outside the pale of the other sciences ceases for the time being to be a science The sooner it returns to the pale of the other sciences the better, and when all are working for a common good the better it will be for the progress of each

Prof. Huxley, in proposing the next toast, said that he had to discourse on the merits of the gentlemen to whom medals had been awarded There was one the adequate treatment of whose merits would occupy the whole available time, and yet Mr Shaw Lefevre wished him to say something about his capacity to become a legislator and also to give an opinion upon geological time He would answer the first interrogation by telling a story. When he was a very young man a solicitor in large practice discovered in him what that gentleman believed qualities that would command success at the Bar, which he had never discovered himself, and proposed to advance him an income for a certain number of years until he could pay the amount back out of the fees he was sure to earn He was sorry to say his reply was this, "So far as I understand myself, my faculties are so entirely confined to the discovery of truth that I have no sort of power of obscuring it" With regard to political life, the absolute contradictions that were made by politicians of opposite sides upon matters of fact were absolutely fatal to his chances in a political career Coming to the subject of the toast, he narrated the history of the Copley medal A bequest of £100 was left to the Society 188 years ago by Godfrey Copley, a Fellow of the Society, for improving natural knowledge The medal was thrown open to all the world, a step much disapproved by certain narrow-minded persons at the time, but that step was the real reason why, a century later, Sir Humphry Davy could really call it "the ancient olive crown of the society" The value of the medal was originally fixed at £5, people being able to get five per cent for their money in those halcyon days He did not like to dwell upon its appreciation now lest the County Council should put in a claim for unearned increment The medal had certainly done nothing for itself, the appreciation of its value had arisen entirely from surrounding circumstances, the chief being the wisdom and integrity of some eighty successive councils A complete list of the awards was published every year. Going back one hundred years from 1887—he had a reason for not taking a later date—the century began with John Hunter, and finished with Joseph Hooker Between them was a galaxy of the heroes of science, French, German, Scandinavian, Italian, American, and English, and, although one star might differ from another star in glory, none was unworthy of its place in the constellation The present council had not fallen below the standard of its predecessors, there was no biologist, no scientific physician, no anthropologist, no archæologist to whom the name of the illustrious Rector of the University of Berlin, Rudolph Virchow, was not familiar No one had done more to put pathology on a scientific foundation, no one had done more for critical anthropology, especially in connection with archæology Without venturing on the dangerous field of politics, he would add that these merits were, to his mind, greatly enhanced by the fact that Virchow had never merged the citizen in the philosopher, but amidst great difficulties and with undaunted courage, he had taken an active, a disinterested, and a thoroughly independent course in the Legislature of his country The next medal in order of age was that founded by Count Rumford at the commencement of this century, on equally cosmopolitan principles, but limited in scope to the physico-chemical sciences In these sciences hardly anything had attracted popular attention more of recent years than the marvellous power which spectroscopy had placed in our hands to discern the chemical composition of bodies which were millions and billions of miles away, and, for anything we knew to the contrary, these minute and careful inquiries into the constitution of stars might be *post-mortem* examinations In the accurate examination of stars by the spectroscope, he understood from others that Dr Dunér, of Sweden, had laid secure foundations for all future investigations The Royal medals were founded by the Sovereign some sixty-odd years ago, were now maintained by her Majesty, and were confined to British subjects. There were two medals every year, and they were usually allotted one to physical and chemical science, and the other to biological science They were usually given to younger men; and it was so in his own case forty years ago The value of the medal was inexpressible to him In his younger days, if a man took to science, it was thought he was going to the bad The receipt of the medal made an entire revolution in the minds of his friends, and he was a respectable person from that time On the present occasion the first of these medals was awarded to the present Director of the Astronomical Observatory in Oxford, Prof Pritchard, and he was told that there was no observatory in the three kingdoms in which so much admirable work of observation was being done Only a short time ago the Royal Astronomical Society awarded its gold medal to the Director of the Oxford Observatory. He was further told that the director was tackling what he understood was one of the most difficult pieces of astronomical work—parallax determination; and that he had already printed off more stars than anybody else. Besides this, he was hard at work on the great international chart of the heavens. It was obvious that this gentleman must be in the

full vigour of youthful energy, and therefore he treated with contempt a rumour that had reached him that the director was in his eighty-fourth year They would join with him in wishing Prof Pritchard a long continuance of the health and strength which were turned to such splendid account The second of these medals was awarded to Dr Langley, of the University of Cambridge, for the long-continued and very valuable physiological researches There was a familiar phenomenon observable before sitting down to dinner, and known as watering of the mouth If it were possible to determine the exact condition of that operation in physiology the exact knowledge would be a key to an immense range of the secrets of Nature It was these problems that Dr Langley had been investigating, and he had come nearer to their solution than any one else The Davy medal was awarded to a distinguished French *savant*, M Raoult, whose work was considered of the highest importance, and he rejoiced that the recipient of the medal was present The Darwin medal was instituted in honour of one of his best and dearest friends, and it was now conferred upon a man who was one of the stanchest friends he had had for the last forty years He might fairly appeal to Sir Joseph Hooker's present activity, put him down also among the young men, and thereby save the credit of the council in the matter of its own regulation To those who knew the "Life and Letters of Darwin," talk about Sir Joseph Hooker's right to the Darwin medal was as futile as the attempt to judge Manlius in sight of the Capitol He knew no more remarkable example of life long devotion, of stores of information laid open, of useful criticism, and of still more useful encouragement, by one man to another, than that exhibited by Sir Joseph Hooker in this picture It might be that even the man whose motto was "It's dogged as does it," and who so patiently laboured for half a lifetime at the great fabric of the origin of species, might have fainted by the way without this friend's aid And assuredly Hooker's great study of geographical distribution was a most important factor in Darwin's work It lay in the eternal fitness of things that Wallace and Hooker should receive the Darwin medal, and that these old young men should give it a heightened value for the young young men to whom it would hereafter pass

Prof Raoult returned thanks, speaking in French.

Dr Langley responded for the other medallists and himself

Sir James Paget briefly proposed "The Guests"

The Swedish Minister, in responding, said—The honour to be your guest and to participate with you in the celebration of this interesting day cannot be more thankfully felt than by me, who still has to consider this favour, above all, as a compliment to the country where you have selected this year your Rumford medallist This distinction to my fellow-countryman, Prof Dunér, whose merits Prof Huxley has so eloquently explained to you, is a new link in the long chain of tokens of sympathy and appreciation from this society to scientific Scandinavians, a chain of which one of the oldest links is the creation of the Linnean Society More than a hundred years have passed since, and in the meantime many systems have been altered, and, especially in the last twenty years, those alterations have so closely followed the one upon the other that we laymen have been accustomed to believe we were entitled to ask every new morning, "What great discovery will this day bring?" In one department, however, scientific men as well as laymen cannot admit the possibility of any alteration, and that is in our conviction and belief that this country occupies a prominent place in the universal scientific movement—a proof of which, among many others, is the fact that no other institution in the world encourages as much as does this society other countries' scientific researches

Mr. Alma-Tadema also responded, remarking in the course of his speech that there was no art without science, neither was there any science without art and that art coloured life as the sun colours the flowers of nature

AZOIMIDE

A FURTHER communication concerning azoimide, the interesting compound of hydrogen and nitrogen, N_3H, discovered two years ago by Prof Curtius, is contributed to the current number of the *Berichte* by Drs. Noelting and Grandmougin of Mülhausen, in conjunction with Herr O Michel. As described in our note of vol. xliv p. 600, Drs. Noelting and Grandmougin have previously shown that azoimide may be obtained by indirect means from the singular compound prepared somewhere about the year 1866 by the late Dr Peter Griess, and which has hitherto been known as diazobenzene imide, $C_6H_5{-}N\left\langle\begin{matrix}N\\ \|\\ N\end{matrix}\right.$ This compound is now recognised as the phenyl ester of azoimide It is, however, a substance of very considerable stability, and successfully resists the attack of concentrated alcoholic potash, even under pressure Although thus stoutly resisting direct attack, Drs Noelting and Grandmougin have shown that by undermining its constitution by the introduction of a couple of nitro groups in the place of two hydrogen atoms, it becomes weakened so greatly as to be no longer capable of withstanding the action of the alkali, and is decomposed with production of the potassium salts of azoimide and dinitro phenol—

$$C_6H_3(NO_2)_2N_3 + 2KOH = C_6H_3(NO_2)_2OK + N_3K + H_2O$$

This interesting result is now supplemented by showing that it is not necessary to introduce *two* nitro groups in order to render diazobenzene imide sufficiently negative in character as to be susceptible to the attack of alcoholic potash, that *one* such group suffices, provided it be introduced in the para or ortho position A nitro group introduced in the meta position appears to exert much less weakening power, quite inadequate for the purpose

Para nitro diazobenzene imide, , is a substance crystallizing well in colourless tabular crystals When these crystals are allowed to fall slowly into a cold solution of one part of caustic potash in ten parts of absolute alcohol, they instantly dissolve and the liquid becomes coloured a deep red If this red solution is warmed for a couple of days over a water bath, and the larger portion of the alcohol subsequently distilled off, upon acidification of the residue with dilute sulphuric acid, and again distilling, azoimide, N_3H, passes over along with the vapours of water and alcohol In order to free the azoimide from alcohol it is only necessary to neutralize the distillate with soda, and evaporate the solution to dryness, when the sodium salt of azoimide, N_3Na, is obtained, the sodium salt is then dissolved in water, the solution acidified with sulphuric acid, and subjected to distillation, when an aqueous solution of azoimide is obtained The yield of azoimide is usually only about 40 per cent. of the theoretical, owing to secondary reactions which occur simultaneously with the main one The ortho compound,  treated in a similar manner, also furnishes azoimide to the extent of about 30 per cent. A very much larger yield, about 85 per cent, is afforded by the dibrom derivative of the para compound,  a substance which is readily obtained in the form of long colourless prisms. Azoimide has also been obtained to the extent of 30 per cent. of the theoretical amount by the decomposition of a nitro toluene derivative of azoimide of the constitution 
THE NEW STAR IN THE CONSTELLATION OF AURIGA[1]

THE appearances which the new star has presented were exceedingly remarkable, and observations, both spectroscopic and photometric, were far more numerous than have been obtained during former occurrences of this kind The latter have been sufficient to establish the unsuitability of several explanations which have been suggested with regard to former new stars, suggestions which at the time appeared more or less plausible On the other hand, however, it is very difficult to establish, from the publications of observers up to the present time, all details required for a general proof of a definite hypothesis It appears to me appropriate to suggest a new attempt at explanation, which seems to tally better than others with the principal results of observation, the final tests of which hypothesis must, however, for the present remain a matter for the future But if this attempt should in the present instance meet with difficulties—a case which I admit to be possible, if not probable—it yet deserves a somewhat more detailed explanation, because it thoroughly takes account of, as I believe, possible conditions, and therefore certainly contains a possible hypothesis with regard to the appearances of certain new stars In the following remarks I shall strictly adhere to the facts which are to be considered, according to the statements of the observers, as the result of their observations, whereas a proof of the latter is beyond the limit of this article I may here mention that I have already suggested the most essential of the following remarks in March of the present year.[2]

The chief results of observations, which may be said to contain the characteristics of all the appearances, are —

1 According to Herrn Lindeman[3] the light curve of the Nova presented the following appearances —

"From February 1 to 3 the photometric curve rises quickly to a brightness of 4 7m, then gradually sinks till February 13, and then quicker until February 16 to 5 8m, reaches a second maximum of 5 14m on February 18, has a second minimum on February 23, likewise of 5 8m, and then a third maximum on March 2 again of 5 4m, upon which it sinks till March 6, slowly at first, and then quicker, in a straight line till March 22 down to 9 3" I may here add that from the photographs taken at Harvard College, it was possible to show that the star became visible from the beginning of December, 1891, that already in the period of time December 20–22 it showed a maximum of brightness which reached almost, but apparently not entirely, a maximum on February 3

2 The spectrum of the Nova was most remarkable Prof Vogel, in summing up the results obtained at Potsdam,[4] writes —

"The observations have led to the exceedingly interesting result that the spectrum of the Nova consists of two superposed spectra, and that a number of lines, especially those of hydrogen, which appear bright in one spectrum and dark in the other, are closely adjacent to one another This fact admits of hardly any other explanation than the presence of two bodies, the component motions of which in the line of sight are very considerable . The bodies separate from one another with a relative velocity which during four weeks' observations (in February) suffered no appreciable change, and which amounted to at least 120 miles per second" It may be further added[5] that among the very broadened bright lines there were noted several intensity maxima, two being especially striking

It has been suggested as an explanation of the facts of observation that two heavenly bodies have passed very close by one another, and that thus changes in their atmospheres have arisen which have caused the sudden brightening up of the bodies The above hypothesis is, however, in this form too vague to be followed in detail In reverting to an idea of Klinkerfues, it is true that a more distinct picture of the whole occurrence has been drawn, by assuming tidal effects of the two bodies upon each other in this manner where the tidal crests of the atmosphere appear, there the darkenings take place by absorption, and where the ebb predominates a brightening is the result, because here the absorbing strata of the atmospheres are less powerful It must be mentioned, however, that the statical theory of Ebb and Flow that has been applied is altogether inappropriate to give an idea of the deformations which doubtlessly occur at such a near proximity The effect of the two heavenly bodies on each other in Nova Aurigæ, as is still to be shown, would have to be one that is almost always suddenly appearing and immediately afterwards vanishing Moreover it must not be overlooked, that with incandescent bodies their atmospheres must be regarded as outward shells which quite gradually emerge into denser strata, while these also are deformed in a lesser degree In other respects, too, it will be difficult to explain the appearances of a new star as a consequence only of the effects of absorption of atmospheres It has also been assumed for the most part that besides these (absorptions), eruptions of gas from the centre of the body take place This assumption, it is true, contains nothing impossible, but without a definite form it hardly admits of discussion At all events it will be necessary to suggest further hypotheses in order to apply this attempt at explanation to single cases Moreover, it remains yet unexplained why in Nova Aurigæ the one spectrum is chiefly an absorption spectrum and the other a gas spectrum By special assumptions this difficulty can be certainly eliminated, but it is not very probable that on this account confidence can be placed in the correctness of the hypothesis

Other facts appear, however, in the case of Nova Aurigæ which do not speak in favour of this hypothesis, however generally it may be expressed It is at least very striking that just in this case such enormously great velocities of cosmical bodies appear, such as have hitherto not been found anywhere else The occurrences of these velocities must therefore be numbered among the facts to be explained Further on formulæ will be given from which, at least to a certain degree, the mechanical conditions of the close approach of two bodies can be computed From this it follows that in the case of Nova Aurigæ the two bodies can describe a parabola round each other only if their masses are much larger than 15,000 times the sun's mass. For a hyperbolic movement one can obtain an essentially smaller value of the mass, by assuming that the enormous relative velocity of 120 miles observed has been produced to a small degree by attraction and has existed almost entirely from the beginning Thus the choice is left between the assumption of extremely large masses or the giving up of an explanation of the great relative velocity Neither of these two assumptions contain, it is true, an impossibility, but I do not think that doubtful proofs for the correction of the hypothesis can be noticed in either of them According to my opinion they rather render it (the hypothesis) very little plausible

The formulæ already mentioned indicate what will be explained further on, namely, that the supposed effect of the two bodies, in the case in hand, must have taken place very quickly indeed, perhaps even in the period of a few hours. This effect must necessarily have occurred upon the first brightening up (beginning of December 1891) Why then the Nova attained several weeks later (beginning of February 1892) a second maximum, and to all appearances a greater maximum, and why the light curve sank only very little till the beginning of March but afterwards very rapidly, seems to me, on the ground of the hypothesis in question, to be explainable only with great difficulty, if it can be explained at all. At all events, this difficulty will remain unless it be altogether removed in detail

The difficulties hinted at above entirely disappear in the following supposition. There is no doubt, especially in accordance and with the results obtained from stellar photographs, in which Mr. Max Wolf has co-operated, that space is entirely filled with more or less extensive formations of very thinly scattered matter With regard to their physical properties, these formations will probably show very varied constitutions, the reason for which we will leave an open question, as we do not wish to investigate it here. It is itself not very improbable that a heavenly body should get into such a cloud, but in any case it is more probable than the grazing together of two compact bodies, as is required in the above-discussed hypothesis. As soon now as the body commences to enter a cosmic cloud a surface heating will be set up at once, and indeed it must be so, whatever may be the constitution of the thinly-scattered matter In consequence of this heating, the products of vapourisation will form round the body, these will partly be separated

from it and will adopt very quickly that velocity which the adjacent parts of the cloud possess.

It is interesting to compare this process with a similar one, which takes place in a well-known way in the appearance of shooting stars or fireballs. In this case a compact body enters with a certain velocity into a formation of very thin matter (the upper strata of the atmosphere), is heated and partly vapourized, and a luminous tail, which is clearly visible for a long time after the sudden appearance of the meteor, marks the path which the latter has taken. The detached particles have quickly lost their relative velocities against the air, for they apparently do not partake of the movement of the meteor.

If we consider spectroscopically the star on its commencement to become bright by resistance, two superposed spectra will openly reveal themselves, one in general continuous and provided with absorption bands in consequence of the heaping up of the glowing gases, and the other in the main consisting of bright lines. Both spectra, according to the relative motion in the line of sight, will appear pressed up against one another. Thus altogether an appearance is found very similar to that observed in Nova Aurigæ, and they will agree entirely if one assumes that also those parts of the cloud nearest the body have sustained physical perturbations by a direct frictional warming of the detached particles, &c. This assumption seems to me to contain by no means a difficulty considering our lack of knowledge with respect to the properties of this cloud matter. Whether this is at all necessary I am unable to say on the ground of the publications at hand.

The investigation is important to decide whether, on the lines laid out, we can obtain a plausible explanation of the great relative velocities shown by the two spectra. When the body approaches the cloud the latter will evidently lengthen itself in the direction of the former. This lengthening will grow with the mutual approach, just as the relative velocity of the single parts of the cloud will grow towards the body. Without certain suppositions on the structure of cloud matter it is difficult to conceive of the processes of movement which take place, so we must content ourselves with contemplating the one or the other case, which admits of a closer investigation.

If, for instance, we suppose that the single particles of the cloud follow for the main part the effect of the body, they will describe conic-sections—that is, hyperbolas round the centre of the latter as forces. Their greatest relative velocity decreases quickly with the distance of the body, so that the surroundings of the latter will be filled with particles moving with very different velocities. One can easily see that no very extraordinary assumptions are necessary to suppose very great velocities for these particles that pass near the surface of the body, velocities amounting to those stated in the case of Nova Aurigæ, even if they are at the outset very small. It follows from the above that the spectral lines of the particles which are moving from the body with such different velocities must be very much enlarged, and that to explain the different brightenings of the single parts of the lines as probably intensity maxima does not raise the least difficulty, but is a necessary accompanying phenomenon. This point seems to me to be important, for it cannot be deduced from the hypothesis of two compact masses passing close by one another, and must here lead to the rather improbable assumption of several moving bodies.

As long as the body remains in this, so to speak, atmospheric formation, the appearances above mentioned must always be called forth anew, whence it follows that the peculiarities of the spectrum conditioned by the whole state of things, not considering smaller perturbations, must on the whole remain constant for some time, a point which in the above hypothesis is at first not by any means clear. In a similar manner it will not be astonishing if the star during that time changes its brightness less strongly, while after its exit from the cloud this brightness will decrease rather rapidly. This too agrees with the light-curve in the case of the Nova. Finally, even the periodical fluctuations of the magnitude can be explained quite naturally. We call to mind here the well known fact confirmed lately by the photographs of Max Wolf, that similar occurrences appear in shooting stars, which may, indeed, be explained with difficulty.

We must, however, in any case assume that the star entered the cosmical cloud in question about the beginning of December and left it not long before the beginning of March. Now the question is urged upon us: How was it possible that for such a long time the great relative velocity could remain constant though such a resistance must have taken place that could develope the heat necessary for the glowing of the body? We are here going to decide this question by comparing the resisting power of the star to that of a meteor in the upper strata of our atmosphere.

Let us assume, quite generally, that the motion of the star in a straight line is given by the equation

$$\frac{dv}{dt} = -\lambda v^n \qquad (1)$$

(1) where v is the velocity, n a positive number > 1 and λ a constant, which is directly proportional to the surface of the globular body and the density of the medium and inversely proportional to the mass of the body. We compare equation (1) with the equation for the motion of a meteor

$$\frac{dv'}{dt'} = -\lambda' v'^n$$

in which the time t' is referred to another unit selected for the purpose. If we suppose $v' = \mu v$, $t' = \nu t$, $\lambda = \lambda' \nu \mu^{n-1}$. The latter equation becomes identical with (1), that is the movement of the star corresponds point to point with the motion of the meteor, if the latter equations are satisfied. Representing now m, O, r, δ, m', O$'$, r', δ', as masses, surfaces, radii, and densities of the star and meteor, and D and D$'$ the density of the cosmical clouds and the upper strata of the atmosphere in question, we have —

$$\frac{\lambda}{\lambda'} = \frac{\mathrm{DO}m'}{\mathrm{D'O'}m}, \quad \nu = \frac{1}{\mu^{n-1}} \; \frac{\mathrm{DO}m'}{\mathrm{DO'}m}$$

or also

$$\nu = \frac{t'}{t} = \left(\frac{v}{v'}\right)^n \frac{r'\delta'\mathrm{D}}{r\delta\mathrm{D'}}$$

If we put $r = k$ times the sun's radius (= 700 million metres) and $r = r$ metres, and further corresponding to the observations of the new star $v = 30$ (unit of velocity of Earth in its orbit) and $t = 100$ days and $v' = 2$ which corresponds to a relatively quickly moving meteor and finally $n = 2$, we have —

$$\nu = \frac{15}{k} \; \frac{\mathrm{D}\delta'}{\mathrm{D'}\delta} \; \frac{r'}{700 \text{ millions}}$$

$$\text{and } t' = 0^s \cdot 185 f, \quad f = \frac{r'\delta'\mathrm{D}}{k\delta\mathrm{D'}}$$

Thus the movement of the star takes place proportionally in 100 days, just as that of the meteor in 0.185 seconds if we suppose $f = 1$. As we are free to assume $\frac{\mathrm{D}}{\mathrm{D'}}$ small, we can obtain a very small fraction of a second, and since within a hundredth part of a second the movement in the highest regions of our atmosphere shows no longer a perceptible decrease of velocity, such a decrease will not enter in the case of the star. We have evidently to deal here with the same appearance which points out that small heavy objects possess a far greater resistance to air than large ones, and that with large meteors (fireballs) the air resistance, as it has been proved, influences the elements of the orbit far less than is the case with small meteors.

We have still to show that in spite of the small decrease of movement, enough energy of movement is changed into heat in order to bring the star into a surface-glowing condition, and such a condition has by all means taken place in the Nova. We must therefore calculate the quantities of heat Q and Q$'$ which is radiated in one second of time, and from a unit of surface on both bodies. If we call P and P$'$ the losses in acting power during the times t and t', v_0 and v_0' the velocities before the entrance into the resisting media, we have:—

$$\mathrm{Q} = \frac{\mathrm{P}}{\mathrm{O}t}, \quad \mathrm{Q'} = \frac{\mathrm{P'}}{\mathrm{O'}t'}$$

$$\text{and } \mathrm{P} = m\,(v_0^2 - v^2), \quad \mathrm{P'} = m'\,(v_0'^2 - v'^2)$$

and taking into consideration the above equations:

$$\frac{\mathrm{Q}}{\mathrm{Q'}} = \frac{\mathrm{D}}{\mathrm{D'}}\left(\frac{v}{v'}\right)^{n+1}$$

with the above numbers $\frac{v}{v'} = 15$, n will be $= 2$

$$\frac{\mathrm{Q}}{\mathrm{Q'}} = 3375 \cdot \frac{\mathrm{D}}{\mathrm{D'}}$$

so that we can assume that the density of the cosmic medium, compared to these already very thin air strata, in which evidently

the glowing of the meteor occurs, is not very dense, and that one yet gets the necessary quantity of heat.

It may be remarked that we can vary all these numbers within very wide limits without fearing any contradiction, so that we may conclude, therefore, that no difficulty in the suggested hypothesis arises from this point of view.

I have now to deduce the formulæ I have mentioned above, and it will be seen that these are very interesting.

If we take μ as the sum of two masses revolving round each other in a conic section, V the velocity, and retaining for the rest the customary nomenclature, we have for the parabola

$$V^2 = k^2\mu \frac{2}{r}, \quad r = \frac{q}{\cos^2 {}^1/_2 v},$$

$$\tan {}^1/_2 v + {}^1/_3 \tan^3 {}^1/_2 v = \frac{k\sqrt{\mu}\, t}{q^{3/2}\sqrt{2}}$$

Whence it follows without further difficulty

$$\mu = \frac{V^3 t}{4k^2 \sin {}^1/_2 v\,[1 - {}^1/_3 \sin^2 {}^1/_2 v]}$$

One takes c as the velocity of the earth in its orbit with the radius R and puts the sun's mass and the mass of the earth = 1, so that $k^2 = c^2 R$. If we consider further that the expression

$$\sin {}^1/_2 v\,[1 - {}^1/_3 \sin^2 {}^1/_2 v]$$

can attain the maximum value $\frac{\sqrt{2}}{3}$, it follows that

$$\mu > \frac{3}{4\sqrt{2}} \left(\frac{V}{c}\right)^3 \cdot \frac{ct}{R}$$

or if t be given in solar days

$$\mu > 0.00912 \left(\frac{V}{c}\right)^3 t \tag{4}$$

To apply this to the Nova we must remember that $\frac{V}{c} > 15$, because the orbital velocity may be greater than that in the line of sight. Besides, more than two months have passed since the supposed grazing of the bodies took place, which time must coincide closely with that of perihelion, up to the time that we have still spectrum observations in hand. Thus t is much greater than 60. Formula (4)—

$$\mu > 14779 \times \text{sun's mass}$$

gives thus a limit which supposes masses far too small. In reality we might perhaps assume double this without challenging contradiction.

The consideration of a hyperbolic movement takes a similar though less simple form.

If V_0 represents the velocity at an infinitely large distance, we have

$$V^2 - V_0^2 = \frac{2k^2\mu}{r},$$

and according to the Theoria Motus—

$$\frac{r}{a} = \frac{e - \cos F}{\cos F},$$

$$e \tan F - \log \tan (45° + 1/2\, F) = \frac{k\sqrt{\mu}\; t}{a^{3/2}},$$

from which it is found at once that—

$$\left.\begin{aligned} \mu &= \left(1 - \frac{V_0^2}{V^2}\right)^{3/2} \left(\frac{V}{c\sqrt{2}}\right)^3 \frac{ct}{R} X \\ X &= \left(\frac{e - \cos F}{\cos F}\right)^{3/2} \cdot \frac{1}{e \tan F - \log \tan (45° + 1/2\, F)} \end{aligned}\right\} \tag{5}$$

The expression for X, if one allows F to vary from 0°–90°, first decreases, reaches a minimum, and then increases to infinity. The minimum value can easily be determined for then

$$\frac{3}{4}\frac{e \sin 2F}{(e - \cos F)^2} [e \tan F - \log \tan (45° + 1/2\, F)] \text{ must be } = 1$$

This equation can be easily solved for special values of e. For the theoretical calculation which is requisite, I have employed another proceeding, as I have already computed the serial values of X for a special value of e, as the following table shows:—

	$e = 1.5$	2.0	4.0	6.0	8.0	10.0
F = 4	10.207	14.393	24.882	32.111	37.988	43.071
8	5.224	7.302	12.554	16.182	19.135	21.689
12	3.614	4.987	8.494	10.930	12.913	14.630
16	2.852	3.866	6.505	8.348	9.853	11.156
20	2.429	3.226	5.345	6.835	8.059	9.118
24	2.178	2.827	4.603	5.806	6.902	7.802
28	2.017	2.569	4.343	5.204	6.112	6.902
32	1.941	2.400	3.753	4.740	5.555	6.265
36	1.900	2.293	3.510	4.411	5.158	5.810
40	1.892	2.234	3.345	4.181	4.877	5.486
44	1.911	2.211	3.240	4.029	4.688	5.266
48	1.953	2.220	3.187	3.941	4.574	5.131
52	2.017	2.257	3.179	3.911	4.528	5.072
56	2.101	2.323	3.217	3.936	4.547	5.086
60	2.208	2.420	3.301	4.020	4.633	5.175
64	2.341	2.552	3.438	4.170	4.797	5.351
68	2.510	2.729	3.644	4.404	5.056	5.635
72	2.728	2.968	3.944	4.754	5.451	6.070
76	3.026	3.307	4.390	5.286	6.055	6.739
80	3.477	3.830	5.108	6.152	7.048	7.843
84	4.308	4.802	6.480	7.824	8.972	9.991
88	6.991	7.938	10.960	13.320	15.321	17.091

For very large values of e the minimum of X occurs if

$$\sin F = \sqrt{2/3},$$

and the minimum value of X becomes

$$\text{Min X} = \sqrt{\frac{3\sqrt{3} \cdot e}{2}} = 1.612\sqrt{e} \tag{6}$$

But one practically commits no error if one employs (6) also for the values of e nearly equal to 1, as is evident from the following computation of the minima values taken from the above table, and calculated according to formula (6).

e	Direct	Formula
1	1.5	1.6
1.5	1.9	2.0
2	2.2	2.3
4	3.2	3.2
6	3.9	3.9
8	4.5	4.6
10	5.1	5.1

One obtains:—

$$\mu > 0.0104\left(1 - \frac{V_0^2}{V^2}\right)^{3/2} \left(\frac{V}{c}\right)^3 \sqrt{e}\; t \tag{7}$$

For the above assumptions—

$$t = 60, \; \left(\frac{V}{c}\right) = 30,$$

we find

$$\mu > 16850\sqrt{e}\left(1 - \frac{V_0^2}{V^2}\right)^{3/2}$$

which formula holds good for values of e, which do not quite equal 1. In order to include also the parabola we suppose

$$\mu > 15000\sqrt{e}\left(\frac{V^2 - V_0^2}{V^2}\right)^{3/2} \tag{7a}$$

Thus in this case we result in extremely large masses, which are not very probable, or we must assume that $\frac{V_0}{V}$ = very nearly 1. Even for $\frac{V_0}{V} = 0.9$, according to the above formula, $\mu > 1200\sqrt{e}$, and we may consider the above given assertion as justified. It has already been remarked that this suggested inequality proves only that μ is very much greater than the right side (of the equation).

It is easy to find a higher limit for μ if $\frac{V_0}{V}$ does not differ much from unity.

If we put $\frac{V^2 - V_0^2}{V^2 + V_0^2} = \nu$, we obtain $\cos F = \nu e$, and according to formula (5)

$$\mu = \left(\frac{1 - \nu}{1 + \nu}\right)^{3/2} \left(\frac{V}{c}\right)^3 \frac{ct}{R} \cdot \frac{\nu}{e\nu \tan F - \nu \log \tan (45° + 1/2\, F)}.$$

Given t, e, and ν, we can calculate the right-hand side. But we seek, however, the maximum value of

$$y = e\nu \tan F - \nu \log \tan (45° + 1/2F) = \sin F - \nu \log \tan (45° + 1/2F)$$

by determining e as function of ν. It is

$$\frac{\partial y}{\partial e} = \left(\cos F - \frac{\nu}{\cos F}\right)\frac{\partial F}{\partial e} = \frac{\nu(1 - \nu e^2)}{e\sqrt{1 - \nu^2 e^2}}$$

Thus y increases so long as $e < \frac{1}{\sqrt{\nu}}$, and decreases continually for $e > \frac{1}{\sqrt{\nu}}$. The maximum for y takes place when $e^2 = \frac{1}{\nu}$, and is

$$y = \sqrt{1 - \nu} - \nu \log\left(\frac{1 + \sqrt{1 - \nu}}{\sqrt{\nu}}\right)$$

Thus we have

$$\mu > \frac{ct}{R}\left(\frac{V}{c}\right)\left(\frac{1 - \nu}{1 + \nu}\right)^{3/2} \frac{\nu}{\sqrt{1 - \nu} - \nu \log\left(\frac{1 + \sqrt{1 - \nu}}{\sqrt{\nu}}\right)}, \qquad (8)$$

and with $\frac{V}{c} = 30$ and $t = 60$ days,

$$\mu > 27800\left(\frac{1 - \nu}{1 + \nu}\right)^{3/2} \frac{\nu}{\sqrt{1 - \nu} - \nu \log\left(\frac{1 + \sqrt{1 - \nu}}{\sqrt{\nu}}\right)}$$

For the above example $\frac{V_0}{V} = 0.9$ results $\mu > 2800$ as considerably larger masses than formerly.

I have now further to prove that a very close proximity of the two bodies can have only taken place for a very short space of time. To do this we use the following relations.

We find above for the parabola

$$\mu = \frac{V^3 t}{4k^2 x}, \quad x = \sin \tfrac{1}{2}v(1 - 2/3 \sin^2 1/2v)$$

It follows, therefore, that

$$V^2 = \frac{2k^2\mu}{r}$$

$$r = \frac{Vt}{2x}$$

Thus we have

$$r > \frac{3}{2\sqrt{2}} \quad Vt = 1.06Vt \qquad (9)$$

For the hyperbola we have

$$r = \frac{2k^2\mu}{V^2 - V_0^2}$$

and, according to formula (5)

$$2k^2\mu = \frac{(V^2 - V_0^2)^{3/2}}{\sqrt{2}} tX$$

Therefore,

$$r = \frac{\sqrt{V^2 - V_0^2}}{\sqrt{2}} tX$$

For eccentricities which are not very nearly equal to 1, we had

$$X > \frac{3^{3/4}}{\sqrt{2}} \quad \sqrt{e},$$

and it is certainly

$$r > \frac{3^{3/4}}{2} \sqrt{e} \sqrt{V^2 - V_0^2} \quad t > 1.05 \sqrt{V^2 - V_0^2}\, t \qquad (10)$$

For $V_0 = 0$

(10) is naturally changed into (9). For the hyperbola, however, it is possible to suggest a second relationship.

Since

$$2\frac{a}{r} = \frac{V^2 - V_0^2}{V_0^2}.$$

(5) can also be written

$$k^2\mu = \left(\frac{a}{r}\right)^{3/2} V_0^3 tX$$

and because $k^2\mu = aV_0^2$, it follows that

$$r = \sqrt{\frac{a}{r}} \quad V_0 tX = V_0 ty,$$

where

$$y = \frac{e - \cos F}{\cos F} \cdot \frac{1}{e \tan F - \log \tan (45° + 1/2F)}$$

An easy calculation yields now

$$\frac{\partial y}{\partial F} = \frac{-1}{e \sin F - \cos F \log \tan (45° + 1/2F)} [(1 + e^2) \cos F - 2e + e \sin F \log \tan (45° + 1/2F)].$$

It is quite evident that the quantities in brackets always remain positive, for it is

$$\log \tan (45° + 1/2F) = 2 \tan \tfrac{1}{2} F + \tfrac{2}{3} \tan^3 1/2 F + \ldots > 2 \tan 1/2 F,$$

and in consequence of it the quantity in brackets $> (e - 1)^2 \cos F$.

Thus, $\frac{\partial y}{\partial F}$ is negative, and y decreases as F increases. From this it follows that $y > 1$, and the relation $r > V_0 t$, is the result.

If we apply this formula to Nova Aurigæ, we obtain for

$\frac{V_0}{V}$	$\sqrt{V^2 - V_0^2}$	V_0
0.5	108 miles,	60
0.6	96	72
0.7	86	84
0.8	72	96
0.9	—	108

In the vicinity of perihelion the velocity has been under every condition greater than 120 miles, and we shall therefore obtain values of r that are considerably too small, by supposing $r > t \times 85$ miles. One day before or after perihelion it is therefore certain that $r > 7.3$ million miles.

It will therefore hardly be possible to assume that any noticeable influence of the supposed two bodies can have lasted longer than a few hours.

Since the above article was written Nova Aurigæ has by its reappearance attracted considerable attention, and especially by the observation as made by Prof. Barnard. With regard to this reappearance one must necessarily see an evident confirmation of the critical part of my article. Nor has my hypothesis been contradicted in any way, for it is evident in itself that the supposed formations of the nebulous or dusty matter are more copious in certain parts of space, and one may have different ideas of the distribution of density of these formations.

To the observation made by Prof. Barnard (*Astr. Nach.*, 3114) I wish to add the following remarks. I had formed an idea of the whole process which caused the outburst of the Nova, which idea is as perfectly represented in Prof. Barnard's drawing, kindly communicated to me by Prof. Kreutz, as I could expect. During the appearance of the Nova in the winter nothing similar was seen so far as I know. It does not follow from this, therefore, that it did not exist, and it would also have been possible to have expected information from the photographs as has often occurred before. I applied on this account to Dr. Wolf, in Heidelberg, and asked him whether he had photographs of the region of the Nova at that time, and whether, perhaps, any nebulous object was to be seen on them; but, unfortunately, Dr. Wolf did not possess such photographs. It remains doubtful, I am sorry to say, whether so delicate an object would have been visible on the plates. W. J. LOCKYER

HINTS FOR COLLECTORS OF MOLLUSKS.[1]

AFTER the collector has brought home the spoils of his excursion there is still a good deal to be done before the wet and dirty shells, covered with parasitic growths or inhabited either by the original mollusk or some hermit crab, will be ready to be placed in the cabinet. Some of them, if living, may find a temporary place in an aquarium for the study of their habits, but, for the most part, the collector will wish to prepare his specimens either for anatomical use in the future or as dry specimens for his cabinet. The preparation of mollusks for anatomical purposes has been described in a special chapter of these instructions. For ordinary rough work nothing is better than clean 90 per cent. alcohol diluted with a proper proportion of water. If the specimens are large they should be first put into a jar kept for that special purpose, in which the alcohol is comparatively weak, having, say, 50 per cent. of water added to it. After the immersion of specimens in this jar for several days the fluids will have been extracted by the alcohol, and a specimen can then be removed, washed clean of mucus and dirt, which will almost always be found about the aperture of a spiral shell, and

[1] Reprinted from "Instructions for Collecting Mollusks, and other Useful Hints for the Conchologist," by William H. Dall; issued by the Smithsonian Institution as Part G of *Bulletin* of the U. S. National Museum, No. 39.

placed in its own proper jar of 90 per cent alcohol diluted in the proportion of 30 per cent. with pure water Specimens to be prepared for the cabinet require the removal of the soft parts if they are still present, the cleaning off of parasitic or incrusting growths, and, in the case of bivalves, securing the valves in a convenient position for the cabinet The different classes of shells may be treated under several heads

Land and Fresh Water Shells

Land and fresh water shells are much more easy to deal with than marine shells. In the case of spiral shells, such as *Limnæa*, *Planorbis*, *Paludina*, &c , the shell may first be washed clean of mud or comfervoid growth, which may be conveniently done with the assistance of an old tooth or nail brush In the case of these forms the easiest way to remove the soft parts is to place the shell for twenty four hours in weak alcohol, after which those parts can readily be removed , but in any case where the expense of alcohol is an object to be avoided, it will be sufficient to place them in a small tin kettle, or other receptacle suitable for the purpose, and cover them with cold water, which should then be slowly brought to the boiling point. As soon as it has reached the boiling point it may be removed from the fire The shells should not be put into water already boiling, as it frequently cracks delicate shells, and the sudden change of temperature injures their polish and general appearance

For removing the soft parts from spiral shells the collector will usually find a crooked pin sufficient For this purpose one of those long steel pins used by ladies as hat pins is convenient By heating the pointed end in the flame of a candle or alcohol lamp the temper can be taken out of the steel, so that it can be readily bent into any shape desired The proper form for reaching the retracted parts in a spiral shell will of course be a spiral. With a small pair of plyers, different forms can be experimented with, and those which are most satisfactory decided upon. After the right form has been obtained, by heating the pin again and plunging it suddenly into cold water, the temper of the steel will be measurably restored and the instrument ready for use Similar pins in their ordinary condition are convenient for cleaning out sand or parasites from the recesses of sculptured shells, and for other purposes The attachment of a gastropod to its shell is at the central axis or pillar of the shell, usually from half a turn to a turn and a quarter behind the aperture. By applying the pressure of the extractor carefully in this vicinity the attachment will give way and the extractor may be withdrawn, bringing with it the soft portions of the animal In large and heavy shells, in which the muscular attachments are strong and deep-seated, and it is desired to obtain a good hold of the animal in order to extract it from the shell ordinary steel fish-hooks may be used These may be softened by heat, straightened out, and twisted into a spiral of the proper form, and retempered Then they can be securely fastened to small wooden handles by the shank of the hook In this way the barb of the hook will assist in retaining the soft parts on the extractor when it is withdrawn from the shell Several German firms advertise sets of implements for cleaning, cooking, and extracting the animals from shells of mollusks, but it would seem to the writer that any person of ordinary intelligence and some little mechanical ingenuity, such as all naturalists are expected to possess, should be able to provide himself with the necessary apparatus without purchasing expensive paraphernalia of this kind. Shells which have no operculum require merely to be cleaned after the animal has been removed, and in the case of land and fresh-water shells this is usually a very simple matter Shells which possess an operculum should retain it in the cabinet, as it is often of great value in determining the relations of the species, since the operculum is a characteristic feature in the economy of the animal It should be detached from the body of the animal after the latter has been extracted from the shell, carefully washed and cleaned, and if flat and horny may be dried between two pieces of blotting paper, under a weight This will prevent it from becoming contorted in the process of drying For removing the thick incrustation of lime and peroxide of iron which frequently forms upon fresh-water shells, a few tools resembling engraver's tools or the little chisels in use by dentists for excavating teeth are very convenient. A suitable tool, however, can easily be made by softening and grinding down an old file to a triangular point. A little experience will enable the collector to become expert in scaling off the objectionable matter without injury to the surface of the shell.

Naked slugs should be preserved in alcohol, after being sketched in the living state Some of the older naturalists had a way of skinning slugs, inflating and drying the empty skins for preservation in their collections, much as entomologists sometimes treat caterpillars , but this ingenious device has nothing to recommend it to a scientific collector, even if he has the dexterity to practise it The internal shell of such slugs as *Limax* may be represented in the collection if desired, but, in any case, specimens should be carefully preserved in spirits.

The bivalve shells, such as *Unio*, if taken alive, may be left in the sun for a short time, when they will usually open, and, the muscle connecting the two valves being cut, the valves may be cleaned It is desirable for cabinet purposes to preserve the two valves in their natural position, attached to each other by the ligament which holds them together in life This ligament dries to a very brittle, horny substance Consequently the shells must be placed in position when fresh in order to make a success of the operation After cleaning away the animal matter and thoroughly washing the interior of the shell, it is a good plan to note the locality with a soft lead-pencil upon the shell itself. Then bring the two valves together in their natural position and tie them in that position with a piece of tape or soft twine, which should be allowed to remain until the ligament is thoroughly dry Specimens prepared in this way are more valuable for exchange and more attractive to the eye than those with which less care has been taken It is always desirable, however, to have some specimens with separated valves of every bivalve species in the cabinet, in order that the characteristics of the interior may be easily examined

Fresh-water bivalves are usually covered with a thin and highly polished, often very elegant, greenish or brownish epidermis. Sometimes the shell is so thin that, in drying, the contracting epidermis splits and cracks the shelly portion so that it becomes worthless for the cabinet This often happens with marine mussels, but it is almost characteristic of the thin fresh-water *Unionidæ* Various methods have been adopted to prevent this unfortunate result Some collectors have varnished their shells immediately after they were obtained. Others have used sweet oil or other oils in the hope of keeping the epidermis in a soft condition These applications are all objectionable for one reason or another, as the first endeavour of the collector who desires to make a really scientific collection should be to keep his specimens as nearly as possible in a perfectly natural condition The most satisfactory substance for application to the shells in question is probably ordinary vaseline, which should be applied in very small quantities, so that the specimen will have no greasy feeling and will absorb the vaseline sufficiently not to become sticky to the touch Glycerine, which has been recommended by several collectors, like oil, leaves the surface sticky and offensive to the touch, besides rendering it liable to catch everything in the way of dust with which it may come in contact

Very small gastropod shells need not have the soft parts removed If they are put into a vial of alcohol for twenty-four hours, then taken out and allowed to dry, the soft parts will become desiccated without any offensive odour, and they may be placed in the cabinet without further preparation. It may be noted, however, that if the cabinet contains many such shells, care should be taken to guard against the access of mice and vermin, which are apt to attack them in the absence of something more attractive in the way of food For those shells which possess an operculum, after the operculum has been dried and the shell cleaned and ready for the cabinet, it is customary to insert a little wad of raw cotton, rolled so as to fit the aperture snugly, the outer surface of it being touched with a drop of mucilage The operculum can then be laid upon this in its natural position and the mucilage and cotton will retain it so without making it difficult to remove for an examination of the shell if desired at any time For the preservation of eggs of mollusks when they have a horny or calcareous shell, small glass tubes securely corked are the best receptacles. Most of these eggs are so small that they may be preserved in a dry state or in alcohol without trouble, but the eggs of some of the tropical land snails are so large that it will be necessary to drill a small hole and extract the fluid contents as if they were bird's eggs in order to preserve them. Such eggs are the best preserved in alcohol.

Marine Shells.

The preparation of marine shells for the cabinet does not essentially differ from that required for land or fresh-water shells, except that in the marine shells the muscular system is

often much more strongly developed and the creatures themselves much larger than the fresh water forms, and the manipulation is therefore somewhat more difficult. The marine forms are also more apt to be incrusted with foreign bodies, bored by predatory sponges, like *Cliona*, or even by other mollusks, or perforated by certain annelids which have the power to dissolve the lime of which the shell is composed, and in this way secure a retreat for themselves.

Shells which do not contain the living animal are frequently occupied by hermit crabs or by tubicolous annelids. The latter fill up the larger part of the spire with consolidated sand or mud, in the centre of which they have their burrow. The hermit crabs do not add anything to the shells which they occupy, but, on the contrary, by their constant motion are apt to wear away the axis or pillar of the shell, so that often a specimen of this sort may be very fairly preserved and yet on the pillar show characters entirely different from those which one would discover in a specimen which had never been occupied by a crab. A shell which the crab has selected for its home is often taken possession of, as far as the outside is concerned, by a hydractinia, a sort of polype, which produces a horny or chitinous covering which is very difficult to remove from the shell to which it is attached. As the hydractinia grows it finally covers the whole shell, to some extent assumes its form, and then, if the creature has not attained its full growth, this is apt to take place around the edges of the aperture, which are continued by a sort of leathery prolongation which assumes in a rough way the form of a shell. The crab, when he grows too large for the shell in which he has ensconced himself, is usually obliged to abandon it and find a larger one, which is always a difficult and more or less dangerous operation, but if his shell is overgrown by the polype referred to, it often happens that the polype and the crab grow at about an equal rate, so that the latter finds himself protected and does not have to make a change. It is supposed that the polype profits to some extent by the microscopic animals attracted by the food or excrement of the crab, so that this joint housekeeping is mutually beneficial, and, for such cases, since the word *parasite* would not be strictly accurate, the word *commensal* has been adopted. These modified shells often assume very singular shapes. The polype is able in the course of time to entirely dissolve the original calcareous shell upon which its growth began, so that if the spire be cut through it would be found throughout of a horny or chitinous nature. Some of the older naturalists were deceived by forms of this sort and applied names to them, supposing that they were really molluscan shells of a very peculiar sort.

In removing the animal matter from the shell of large gastropods it will often require a good deal of time and care to get out all the animal matter from the spire, but it is well worth while to take the trouble, as the presence of such matter forms a constant attraction for museum pests of all descriptions. A medium-sized syringe is convenient for washing out the spire of such shells. The ordinary marine gastropods may be treated in a general way like the fresh-water gastropods. There are, however, abnormal forms, especially among tropical species, which require particular attention. Some species become affixed to corals and overgrown by them, retaining only a small aperture through which the sea water can reach the prisoner. Such specimens are best exhibited by retaining a part of the coral and cutting the rest away, showing at once the mode of occurrence and the form of the covered shell. Borers are always more difficult to handle and prepare for the cabinet than other mollusks. They are usually more or less modified for their peculiar mode of life, and frequently rely upon their burrow as a protection, so that the shell is reduced, relatively to the animal, to a very small size. Most of these forms are best kept in alcohol. The hard parts may properly be represented in the cabinet by other specimens. Some of the bivalves, such as the American "soft clam," possess very long siphons, covered with a horny epidermis, and it becomes a question as to whether an attempt should be made to preserve this epidermis in the cabinet or not. The writer has seen very nicely prepared specimens in which the fleshy portions had all been taken out and replaced by cotton, so that the epidermis of the siphon retained its original position and form; but such specimens are always very delicate, easily broken, and liable to attack by insects, so that it would seem hardly worth while to go to the trouble, when specimens may be preserved complete in alcohol showing all the features referred to. Boring shell-fish, like *Pholas*, frequently have accessory pieces, which are liable to be lost when the soft parts are removed unless care is taken to avoid it. Other bivalves have the internal ligament reinforced by a shelly plate, which is called the ossiculum. This is very easily detached and lost, and, being an object of great interest, special pains should be taken to preserve it, even if it should become detached.

JAPANESE CAMPHOR

THE United States Consul at Osaka gives in a recent report the following particulars, reprinted from the November number of the *Board of Trade Journal*, respecting the Japanese camphor trade:—

The camphor tree, from which the resinous gum is distilled, is a species of the laurel, and is found in the provinces of Tosa, Hiuga, and Satsuma, in the south of Japan. Large groves of the trees are owned by the Japanese Government, the wood being very desirable for shipbuilding. The districts in which the camphor tree is found are mountainous and situated far from the sea. No reliable information can be obtained as to the cost of producing the gum before being transported in junks to Hiogo. The peasants who engage in distilling the roots and branches of the trees are said to be poor, and employ the rudest machinery.

The market value of crude camphor gum and of oil of camphor per picul ($133\frac{1}{3}$ lbs.) during the past year was as follows:—Drained, 38.25 dols.; wet, 37.00 dols.; old dry, 43.50 dols.; average, 36.50 dols.; camphor oil, 5.25 dols.

The highest and lowest prices during the same period were as follows:—Highest, 40.00 dols.; lowest, 33.00 dols.

Camphor gum is exported in tubs measuring about $6\frac{1}{2}$ cubic feet; oil in kerosene tins and cases. The grades are from old dry down to new wet, and the various grades depend upon the quantity of adulteration. In oil there are two grades—white and brown.

Adulteration is practised for the most part by adding water and oil just as far as the buyer will tolerate. In some cases 20 lbs. of water will run out of a tub in twelve hours. The unadulterated article, known as the good old dry, can sometimes be bought. The only system of tests in determining value of the different qualities is by burning and by absolute spirit. The percentage of pure camphor which the crude yields when refined varies according to the quality of the crude. The average percentage of gum produced from the wood as compared with the original weight of the wood cannot be accurately ascertained here, the only foreigner known to have visited the camphor districts having declined to furnish any information on the subject.

The total exports of camphor from Hiogo during 1891 in catties of $1\frac{1}{3}$ lbs. each amounted to 3,850,400 catties consigned to the following destinations: Europe (countries not specified), 1,777,300 catties; London, 335,600 catties; Germany, 209,200 catties; United States, 1,277,000 catties; China, 51,900 catties; France, 199,400 catties.

As regards the manufacture of camphor the following particulars are extracted from a report by the United States Consul at Nagasaki.

Camphor is found alike on high elevations and in the valleys and lowlands. It is a hardy, vigorous, long-lived tree, and flourishes in all situations.

Many of these trees attain an enormous size. There are a number in the vicinity of Nagasaki which measure 10 and 12 ft. in diameter. The ancient temple of Osuwa, at Nagasaki, is situated in a magnificent grove of many hundred grand old camphor trees, which are of great age and size, and are still beautiful and vigorous. It is stated that there are trees at other places in Kiu Shiu measuring as much as 20 ft. in diameter. The body or trunk of the tree usually runs up 20 and 30 ft. without limbs, then branching out in all directions, forming a well-proportioned, beautiful tree, ever green and very ornamental.

The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark-green colour all the year round, except for a week or two in the early spring, when the young leaves are of a delicate, tender green. The seeds or berries grow in clusters and resemble black currants in size and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet-work, while it is used also for shipbuilding. The roots make excellent knees for ships.

In the manufacture of camphor the tree is necessarily destroyed, but, by a stringent law of the land, another is planted

in its stead The simple method of manufacture employed by the natives is as follows —

The tree is felled to the earth and cut into small pieces, or, more properly speaking, into chips

A large metal pot is partially filled with water and placed over a slow fire. A wooden tub is fitted to the top of the pot, and the chips of camphor wood are placed in this The bottom of the tub is perforated so as to permit the steam to pass up among the chips

A steam-tight cover is fitted on the tub From this tub a bamboo pipe leads to another tub, through which the enclosed steam, the generated camphor and oil flow This second tub is connected in like manner with a third The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw, which catches and holds the camphor in crystal in deposit as it passes to the cooling process The camphor is then separated from the straw, packed in wooden tubs of 133½ lbs each, and is ready for market

After each boiling the water runs off through a faucet, leaving the oil, which is used by the natives for illuminating and other purposes

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Cambridge —Mr W Ridgeway, late Professor at Queen's College, Cork, has been elected to the Disney Professorship of Archæology for the customary period of five years Prof Ridgeway's recent work on the origins of weights and measures have made him well known as a scientific archæologist

Mr R T Glazebrook, F R.S , Assistant Director of the Cavendish Laboratory, has been appointed a member of the Financial Board , Mr Lewis, Professor of Mineralogy, and Dr Gaskell, F R S , have been elected members of the General Board of Studies , and Mr E W MacBride, Scholar of St. John's College, has been appointed Demonstrator in Animal Morphology, in the place of Mr J J Lister, of the same College

The Museums and Lecture Rooms Syndicate propose to introduce the electric light into the dissecting room of the Anatomy school, the lecture room, and histology class room of the Department of Physiology, and the Philosophical Library, at an expense not exceeding £100

By the death, on November 30, of Dr F J A Hort, Lady Margaret Professor of Divinity, the University has lost not only a great theologian, but a distinguished student of science Dr Hort was second to Prof Liveing in the Natural Sciences Tripos of 1851, the first ever held He received the mark of distinction in Physiology and in Botany In 1856, and again in 1871, he was an examiner for Honours in this Tripos Throughout his life his interest in the scientific progress of the University was deep and hearty.

A Syndicate has been appointed to consider the whole question of the times of holding Tripos examinations, and the changes that would follow if these were altered The disadvantages of the present system, by which much of the benefit of the Easter term and of the Long Vacation are lost to students and teachers alike, have of late been forcibly brought before the Senate. It is to be hoped that, by bringing about a rational "Easter" or otherwise, the Syndicate's efforts may lead to a reformation.

SCIENTIFIC SERIALS.

American Meteorological Journal, November, 1892.—Wind measurement by H W. Dines. The two instruments generally in use, viz. the Robinson cup anemometer and the pressure plate, are both more or less unsatisfactory in obtaining the extreme pressure. The wind never blows uniformly, whereas the instruments are calibrated on the supposition that it does so. And the method of exposure is often unsatisfactory ; any obstacle to the free circulation of the wind either at the side or even behind or below the anemometer, vitiates the results. The usual factor k for conversion of velocity to pressure in the equation $P = kv^2$ is too high. The value ·005 was given originally in a book on engineering, with a footnote stating that the experiments on which it rested were doubtful, but it has since been copied without the note Recent experiments show that ·003 is probably more correct, but with such a varying element as the wind, any factor is of little use in deducing extreme pressures from velocity anemometers. Instruments of different sizes give different results, and those calibrated by indoor trials give more wind than those tested out of doors In some respects it is more desirable to register the pressure than the velocity, but a pressure plate which is to register 30lb per square foot is hardly suitable to record so small a force as one ounce, so that on many days no sign of motion is given The author concludes from many careful experiments that the tube form of anemometer is most likely to give satisfactory results, as, apart from electricity, it is the only kind in which the motion or pressure can be transmitted to a distance without loss by friction In this instrument the registering apparatus is placed away from the part exposed to the wind —The storms of India, by S M Ballou In this article, which is a continuation of previous papers, the author treats of the storms which accompany the winter and summer rains —The first aerial voyage across the English Channel, by R de C Ward This voyage was successfully carried out by Dr Jeffries and M Blanchard on January 7, 1785 The balloon left Dover at 1h p.m , and descended a few minutes before 4h p m , not far from Ardres —On the production of rain, by Prof C Abbe. The author reviews the natural process of the formation of rain, viz. saturation by aqueous vapour, condensation into visible particles, and the agglomeration of these into drops large enough to be precipitated The problem of artificial formation of rain will be partially solved if some method is invented to bring about a sudden formation of large drops out of the moist air that exists between the small particles of every cloud

SOCIETIES AND ACADEMIES

Paris

Academy of Sciences, November 28.—M d'Abbadie in the chair.—Note accompanying the presentation of a work on the new methods of the "Mécanique Céleste," by M Poincaré —On the existence of distinct nervous centres for the perception of the fundamental colours of the spectrum, by M A Chauveau If one goes to sleep on a seat placed obliquely in front of a window which allows the light from white clouds to fall equally on both eyes, the coloured objects in the room appear illuminated by a bright green light during a very short interval when the eyelids are opened at the moment of awakening The phenomenon is not observed except at the moment of awakening from a profound sleep. From this it is concluded that there are distinct perceptive centres for the green, and probably also for the violet and the red Of these, the green centres are those which first regain their activity on awakening —Note on the observatory of Mont Blanc, by M J. Janssen —On the laws of expansion of liquids, their comparison with the laws relating to gases, and the form of the isothermals of liquids and gases, by E H Amagat The substances examined were water, ether, alcohol, carbon bisulphide, hydrogen, nitrogen, air, oxygen, ethylene, and carbonic acid, the pressures ranging from 50 to 3000 atmospheres, and the temperatures from 0° to 200°. For both liquids and gases, the isothermals present a slight curvature turned towards the axis of abscissæ The angular coefficient increases with the temperature. This effect is specially pronounced in the liquids, where it corresponds to a widening-out of the network, well exemplified in carbonic acid, in the part corresponding to the lower temperatures. This widening-out gradually disappears as the temperature rises , in the lighter gases, the variation with the temperature is very small.—Observations of Holmes's comet ("f" 1892), made at the Paris Observatory (west equatorial), by M. O Callandreau —On a remarkable solar protuberance observed at Rome on November 16, 1892, by M P. Tacchini.—On universal invariants, by M Rabut.—On straight-line congruences, by M. E Cosserat —On the passage of a wave through a focus, by M P Joubin. An apparatus for showing the complementary character of transmitted and reflected Newton's rings is mounted vertically, and illuminated by a small bright point placed at a distance of 1·20m along the axis of symmetry. On moving a microscope along the axis of reflection the rings first appear with a black centre, which changes into white at the first focus of reflection, and again into black at the second.—On the depression of the zero, observed in boiled thermometers, by M L. C Baudin. The secular

depression of the zero, brought into prominence by heating to 100°, may be greatly reduced by keeping the thermometers for several days immersed in a liquid boiling at 400° or 500°.—On the fusion of carbonate of lime, by M. A Joannis —Action of antimony on hydrochloric acid, by MM A Ditte and R Metzner.—On the zincates of the alkaline earths, by M G Bertrand —On anhydrous and crystallized fluorides of iron, by M C Poulenc —Preparation of metallic chromium by electrolysis, by M Em Placet An aqueous solution of chrome alum, to which is added an alkaline sulphate and a small quantity of sulphuric or other acid, is electrolyzed Pure chromium is deposited at the negative pole It is very hard, and of a fine bluish-white colour It resists atmospheric influences, and is not attacked by concentrated sulphuric acid, by nitric acid, or by concentrated potash solution Articles made of brass, copper, or iron may be coated with chromium, thus giving them a metallic lustre resembling oxidized silver Large quantities of the metal can be prepared without difficulty —On the preparation of hydrobromic acid, by M E Léger —Reply to M Friedel's observations on the rotatory power of the diamine salts, by M Alb Colson —Point of fusion of solvents as the inferior limit of solubilities, by M. A Etard —Action of the chlorides of dibasic acids on cyanacetic sodium ether, succinodicyanacetic ether, by M Th Muller —On the functions of hydurilic acid, preparation of potassium hydurilates, by M C Matignon —Researches on the colours of some insects, by M A B Griffiths —Microbicidal action of carbonic acid in milk, by M Cl Nourry and C Michel —On a nervous ganglion of the feet of *Phalangium opilio*, by M Gaubert —Myxosporidia of the bile duct of the Fishes, new species, by M P Thélohan —On the modifications of absorption and transpiration which occur in plants under the influence of frost, by M A Prunet The rapid dessication of the young shoots of frozen plants is due to the substitution of an intense evaporation for the normal function of transpiration, and to an almost complete suspension of absorptive function —*Æcidiconium*, a new genus of Uredineæ, by M Paul Vuillemin —On the classification and the parallelisms of the miocene system, by M Ch. Depéret —On the existence of micro granulite and orthophyre in the primary formations of the French Alps, by M P Termier —On the mineralogical modifications of the calcareous strata in the inferior Jurassic of Ariège due to lherzolite, and their bearing on the history of this eruptive rock, by M A. Lacroix —On the geographical distribution, the origin, and the age of the ophites and lherzolites of Ariège, by M. de Lacvivier —Geological observations on the *Creux de Souci* (Puy-de-Dôme), by M Paul Gautier

BERLIN

Physiological Society, October 28 —Prof du Bois Reymond, President, in the chair —Prof Gad spoke on the respiratory centre on the basis of experiments made in his laboratory by Herr Marenescu. According to these, the centre for the co-ordination of the respiratory muscles lies in the *formatio reticularis grisea* and *alba* below the hypoglossal centre, on each side of the hypoglossal tract, whereas in the apex of the *calamus scriptorius* there is an inhibitory centre (nœud vital) whose stimulation may cause death It further appeared from these experiments that the respiratory centre is not confined to a limited area, but is diffuse and quite distinct from Flouren's "nœud vital"

November 11 —Prof du Bois Reymond, President, in the chair.—Dr. Ad Loewy had investigated the influence on respiration of the upper tracts leading from the cerebrum to the respiratory centre, an influence which is specially marked after section of the vagi. He found that these tracts do not simply hand on to the centre impulses received from the periphery up the trigeminal nerve, but that they automatically maintain the rhythm of the centre after the vagi have ceased to function Dr. René du Bois Reymond spoke on the sensation of warmth which ensues on immersing the hand in a vessel of carbon dioxide. Sulphurous acid, bromine vapour, nitrogen peroxide, ammonia and hydrochloric acid gas produce the same effect. The intensity of the sensation varies with the different gases. Thus carbon dioxide produces the same sensation as air warmed to 20°, while that of nitrogen peroxide is as of air at 30° and that of ammonia and hydrochloric acid gas as of air above 40°. The phenomena do not as yet admit of a physical explanation, but must be regarded rather as resulting from a chemical stimulation of the sensory nerves for heat perception. The President exhibited a torpedo recently born in Berlin, in which he had detected an active electric organ immediately after birth, by means of a nerve muscle preparation and a galvanometer This observation was first made in 1831 by Davy, but had not since then been repeated

CONTENTS.

In the chapter on blood and lymph a fuller account of leucocytes with their varieties and functions, and especially of the proteid and other substances associated with them, would certainly have been desirable. It is of course easy, in reviewing so small a book, to find instances of curtailment and of omission, but the life history of the leucocytes is of supreme importance medically, that even the account of the derivatives of hæmoglobin might, for their sake, have been shortened.

The phenomena of muscular contraction are well described, and the account of muscle and nerve currents is especially clear and to the point.

In the chapter on the vascular mechanism two tracings of pressure in an artificial schema are taken from Prof. Foster's text-book. The tracings are accurately reproduced. In the description of these we are told that, after a high peripheral resistance is introduced into the circuit, "the pressure on the arterial side at first rises with every beat till it has attained a certain height, where it remains stationary, merely oscillating with every stroke of the pump. The venous manometer, on the other hand, shows no rise of pressure, and its oscillations becomes less and less, till they disappear and the flow becomes continuous." A glance at the tracing shows, however, that there is a rise of pressure on the venous side, and moreover a maintained rise. This is a very important point about the tracing. A student grasps readily the action of the arterial blood pressure in forcing the blood from the aorta to the capillaries, but he is at a loss to understand why it comes back again from the capillaries towards the heart. It cannot be too much insisted on that we have a pressure, a small and gradually falling pressure, in the veins, and that this is the important determining cause of the venous flow. The author, in this the proper place to bring this prominently forward, leaves it out entirely, though it is incidentally referred to later on, and leads the student to suppose that the presence of the valves in the veins and the aspiration of the thoracic movements, important though they may be, are the chief factors.

The subject of endocardial pressure and of the pulse is treated, clearly and concisely, in the light of Hurthle's important work. This is particularly welcome, as, if I am not mistaken, this is the first occasion that these researches have been brought before English readers.

In the discussion of the causation of the heart's beat it does not seem clear why "the beat always starts in the sinus" when we are told that the sinus contracts feebly and slowly. The fact that the sinus has a more rapid rhythm than the other chambers of the heart, and so initiates the whole cycle, is not distinctly brought out. The author follows Schmiedeberg's opinion in stating that muscarin acts by stimulating the nerve-endings of the vagus. This is by no means certain, and we should have welcomed some mention of Gaskell's opinion that its action is a direct one on the muscular tissue, and some of the reasons for taking that view. In the description of the vasomotor mechanisms I have found no adequate statement of the important part vaso-dilator nerves play in regulating the circulation in skeletal muscle.

In the account of the nervous mechanism of respiration, which is well up to date, in including some of the results of the work of Head, we should have expected also some statements of Marckwald's observations on the influence of section of the medulla above the respiratory centre. No reference seems to be made of the influence of impulses reaching the respiratory from higher centres of the brain. It is also unfortunate that when the student turns, as directed, to Fig. 61 he finds that the tracing selected of the effect on the respiration of section of the vagi does not show the increase in amplitude as it does the decrease in rate, although he is told that both the changes are brought about. On page 266 there is an obvious misprint, the word "expiratory" should be "respiratory." On page 291 there is another misprint, "B_2" in the equation should be, of course, "Br." A few lines further on there is, however, a serious error. We read, "From the amount of nitrogen given off the amount of urea present in the urine, may be calculated. 35.5 c.c. of nitrogen correspond to one gram of urea." The theoretical amount calculated for one gramme of urea is 372.7 c.c. at standard temperature and pressure, while 35.5, or more exactly 35.4 c.c., is the amount which Hufner found was actually liberated not by one gramme, but by one decigramme of urea.

The chapters on the special senses and on the central nervous system are some of the best in the book. The methods of tracing fibres in the cord and brain are fully gone into, so also is localization of function, and indeed the account of the brain throughout is very clear and good.

At the end of the book is a short appendix, in which is given a description of apparatus purely physical in nature. Every teacher will agree with the author that it is not only desirable, but necessary, to put this in a manual of physiology. The ignorance of the construction and use of the simplest physical apparatus, which the average medical student carries with him into the physiological laboratory, is usually almost as perfect as it can be. Much of the time of a demonstrator of physiology has at first to be given to the teaching of some of the simplest physical methods.
